TELEPHONY AND TELEGRAPHY

AUTOMATIC TELEGRAPHY.—III.

BY P. B. DELANY.

(Concluded.)

THE new system embodies many improvements without which practical use would be greatly hampered. Heretofore the chemical solution was applied to the tape by drawing it from one reel to another through the liquid. Now the tape comes in loosely wound rolls from the factory. They are dropped into the solution bodily. After a few hours' saturation the rolls become solid by absorption of the fluid. Kept in stoneware or dark glass jars with lids, the tape will remain in good condition for several weeks. It is ready for use twelve hours after soaking. The margin of moisture is very wide, as may be seen from the long time it remains in condition. It is less trouble to handle than perfectly dry tape, but, as a matter of fact, it is not handled at all after having been placed on the horizontal reel of the receiver. It is automatically reeled up after passing under the recording wires. One message or twenty may be received at a time.

The spool containing the tape being removable, it is taken to the translator who may use a typewriter or write it out in manuscript. The spool is placed on a spindle to the right of the table, the end of the tape is placed between the pulling rollers of a simple clockwork at the left side of the table, leaving 2½ feet of the tape in plain view of the translator. When this is read, by touching an auxiliary key on the typewriting machine or table, the pulling machine instantly draws another definite length of tape in view. Thus the tape is not handled. No time is lost in shifting copy, and the translator always knows where to begin. Typewritten translation can be made from these plain and unmistakable signals with the same facility and accuracy as from print. An ordinary speed for a translator would be 35 to 40 words per minute, or about twice the speed reached when receiving by sound from the average Morse sending.

A perforating operator will easily equal the Morse operators sending speed, while the typewriter will translate from the tape twice as fast as the sound receiver who is held down to the speed of the sender. In this way there would be a saving of one operator out of three, but even though the receivers in both cases were put on an equality, in what respect does the operation of the automatic system differ essentially from quadruplex Morse? The quadruplex has one actual wire and three "phantom" circuits. Reckoning a perforator and typewriter as being equal to a sending and receiving operator, or a Morse circuit, the automatic system would have one wire and fifty to one hundred phantom circuits, according to distances. No. 1 perforator would work with No. 1 typewriter at the other end. The number of the typewriter for whom the received tape was intended would be the first signal on the tape. Any corrections or other necessary inquiry relating to the business handled by these two people would be exchanged between them alone. Those unaccustomed to it have an exaggerated idea of the difficulties of handling business by automatic, not appreciating the fact that a million words of press news is sometimes handled in a night in the London Main Office in this way.

It is a curious fact that the main objection advanced against the new system is that it is too fast, and would require too many hands to keep it busy. The question is asked, Where could sufficient traffic be found to keep it going? The elastic capacity of the system will, of course, adapt it to any condition, and its excessive efficiency will find employment as soon as the tolls are reduced. The remaining objections raised against the new system are carried over from the old state of the art, viz.: "Nothing to detect an interruption to the circuit during transmission;" and, "Nothing to show when the message is finished," etc. It has been explained and demonstrated on several occasions within the past year that these difficulties have been overcome, and much else besides.

The reel holding the chemical tape is set in motion automatically before any tension is applied to the tape by the drawing rollers, so that it never breaks, and the start is made at full speed. When the sending tape has run through the transmitter the receiving tape is instantly stopped, also automatically, and at the same time a brake is put on the tape reel to prevent accumulation of slack. Not an inch of tape nor an instant of time is wasted. The machine tender knows that when the tape stops transmission is ended. A tell-tale sounder constantly chattering instantly indicates any interruption to the work, and if necessary the machine tender at the receiving end can by pressing a key stop the transmitter instantly at any stage, and upon giving the last word recorded, the transmitter tender pulls back the tape to that word and transmission is resumed. In other words, the receiving operator can "break" the sender as in ordinary Morse. After receiving the signal to start, the transmitting operator has full control over the receiving instrument, starting it simultaneously with the transmitter.

In view of this explanation it is to be hoped that those opposed to machine telegraphy per se will give up going down among the dead men for material upon which to base their objections to a perfectly worked out system of automatic telegraphy of the present day. A great deal of rubbish has been put forth of late on this subject, recounting the faults of a quarter of a century ago and studiously evading acknowledgment of well proven remedies for them all.

This system will transmit and record perfectly legible signals (which any one can translate after a week's practice) at any speed that may be required up to 3,000 words per minute, according to the line employed. It will carry 1,000 words per minute 1,000 miles over a one ohm per mile wire.

To disparage high speed telegraphy the companies take the ground that with their present slow methods of operating they have ample wire facilities for all the business offered. Of this there can be no doubt, but it is folly to argue that, with a system which will increase the capacity of a wire twenty to thirty times over the quadruplex, thereby warranting a reduction of rates to about one-quarter of the present tolls, would not increase the business to an extraordinary degree.

In the United States the average number of letters per head per annum is 36; postal cards, 7; telegrams, about 1, and the average cost of a telegram is 30 cents for ten words. If fifty words can be sent for 15 cents, surely a large proportion of the communications now sent by mail will be telegraphed—leaving the present companies all the business they are now doing. An automatic system using the magnificent postoffice system of collection and delivery, and practically eliminating the railway time, would attract a large portion of the correspondence now going by train, amounting to about seventy million dollars per year, especially between points widely separated, such as New York and Chicago, and all cities beyond.

If it pays to erect and maintain two copper wires 1,000 miles for 60 words conversation per minute, it ought to be profitable to put the same amount of copper in one wire and record 1,000 words per minute, and if the 300 words resulting from a five-minutes' talk at a cost of nine dollars between New York and Chicago can be delivered typewritten for 90 cents, it is reasonable to expect that there will be a field for the new system.

It is thought that in this country at least the time is near at hand when all cities of 25,000 inhabitants and upward will be connected up by large copper conductors, few in number but great in carrying capacity, and that all correspondence of any urgency will be carried by them. The old cries of induction, static capacity, etc., have lost their significance.

When it is proposed to lay down an Atlantic cable having in its initial construction ample compensation for all these obstacles, it seems absurd to say that a bare copper wire on poles accessible at every foot cannot be balanced so as to carry signals at the highest rate of its conductivity.

Comparisons made from the most careful study of the subject show that by the new automatic system one wire is made equal to 100 Morse circuits simplex, 50 duplexes, 25 quadruplexes, or seven Wheatstone duplexes, and that by reason of its simplicity it is adaptable to almost every class of traffic. Five or six drop copies of press matter can be made without serious detriment to through working, or the same tape can be used any number of times on different circuits for news distribution. Traffic can be exchanged with any number of stations on a way wire in rotation from a central or terminal point. Repeaters will not be necessary even on the longest circuits, for the slowest speed working through will exceed the highest reliable repeater working.

An Atlantic cable nearly 2,000 miles in length having 650 pounds of copper per mile is operated at 50 words per minute with 40 volts. A wire of 850 pounds of copper per mile be-

tween New York and San Francisco, 3,500 miles, with about one-eighth the total electrostatic capacity, should yield at least 250 words a minute by the automatic system, using 300 volts, and having recourse to all the compensating expedients well understood in modern telegraphy.

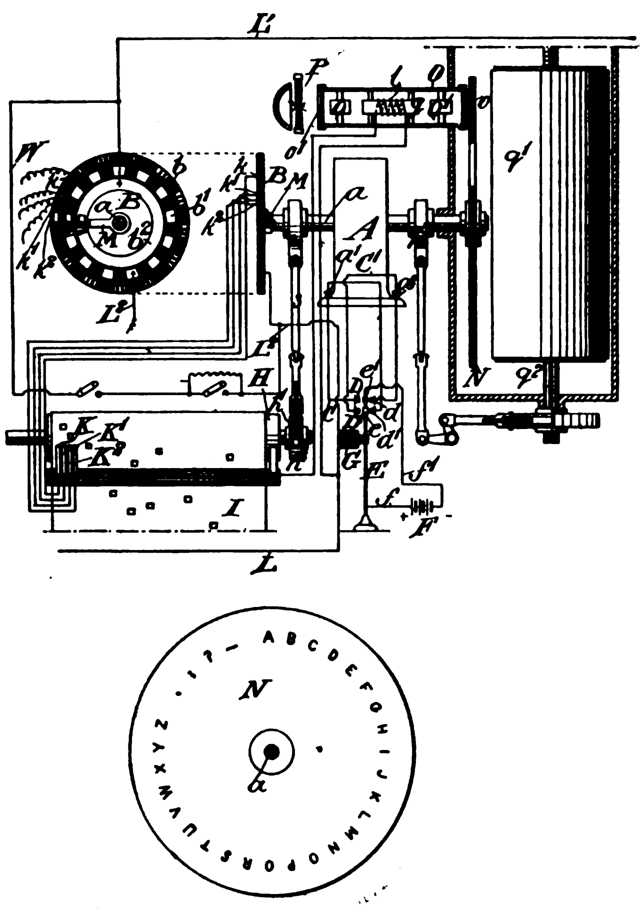
South Orange, N. J.

THE EATON PHOTOGRAPHIC PRINTING TELEGRAPH.

BY C. F. EATON, JR.

THE chief desideratum for a telegraph instrument is that it shall secure the transmission and receiving of ordinary messages, provide for express service and the transmission of a larger amount of intelligence automatically at a high rate of speed which shall entail the least amount of time and labor, with a simplicity of construction that will enable its easy use by any practical telegraph operator.

It is evident that this instrument must be of the printing class if the labor and time of receiving and translating are to be much lessened. Heretofore the main faults of this class of instruments has been their lack of speed for automatic work and their complexity, involving as it does a special training of the operator. This lack of speed in printing instruments is largely due to the fact that in all of them the printing mechanism has to be stopped for an instant for each character transmitted.



EATON PHOTOGRAPHIC PRINTING TELEGRAPH.

The following is a description of an automatic instrument in which the printing is done by the aid of light and instantaneous photography, obtaining thereby, it is claimed, a speed equal to the chemical telegraph in actual transmission over the line besides having all the advantages in speed and otherwise of the printing telegraph and is believed by the writer to meet all the requirements above stated.

The following is a description of the apparatus and its methods of operation: A represents an alternating current motor, a its armature shaft, in axial alignment with a commutator, B. The arm E serves as a pole-changer by making contact alternately with the two sets of contact pieces under the influence of an electro magnet, G, toward and away from the core of which the positive pole of the arm, E, is drawn and driven as the magnet, G, receives the alternating pulsations from the line-wire with which it has a shunt connection, as will be described later. The roller, H, is adapted to receive the perforated pattern strip, I, and cause it to pass step by step in engagement with a series of electric conducting brushes, $K\ K'\ K^2$, etc., one for each character within the scope of the instrument. These brushes, when opposite a perforation in the strip I, make electric contact with the roller, H, and through it with the line-wire, L, coming, as shown, from the left to the instrument, and including at the station here illustrated a helix, l, for operating a shutter.

The commutator, B, consists of three concentric rings $b\ b'\ b^2$, insulated from one another and the whole fixed relatively to the motor shaft, a, with which the commutator is in alinement. The outer ring, b, has alternate spaces of contact and insulation of equal length, the middle ring, b', similar alternating spaces of contact and insulation, but arranged to alternate radially with the spaces on the outer ring, viz., to bring an insulation-space on the middle ring radially opposite a contact space on the outer ring—and the inner ring, b^2, has a continuous annular contact surface.

The contact spaces on the outer ring, b, are provided with groups of contact points, $k\ k'\ k^2$, one for each character within the scope of the instrument and each electrically connected with its coresponding brush, $K\ K'\ K^2$. A trailer, M, carried by the motor shaft, a, is so located as to sweep the faces of the three rings, $b\ b'\ b^2$, with each revolution of the shaft, a, and in so doing make electric contact between each of the points, $k\ k'\ k^2$, etc., and the contact face of the inner ring, which is in permanent connection with the outgoing main-line wire, L', at the right, as shown. As the trailer passes over the alternate insulation spaces on the outer ring it will make electric connection between the contact spaces on the middle ring, b', and the inner ring, and hence will electrically connect the outgoing wire, L', with the shunt-wire, L^2, which connects the middle ring, b', with the incoming main-line wire and includes the magnet, G. The alternate contact and insulation spaces on the commutator are made to correspond to the pulsations of the alternating current, the positive pulsations being received through the outer ring, inner ring, and main line, L', to operate the shutter at a receiving station, and the negative pulsations being returned through the line-wire, L', inner ring, b^2, middle ring, b' magnet, G, and line-wire, L, to the origin of the main line current.

As the positive pulsation passes along the main-line wire it will render the magnet, G, neutral with respect to the positive pole of the arm, E, and it will swing into contact with the pieces, d d', causing the current from the battery, F, to pass through the magnet of the motor, A, and when the negative pulsation passes along the main-line wire it will cause the magnet, G, to attract the arm, E, and hence draw it into contact with the pieces, D D', and hence cause the current from the battery, F, to pass in the opposite direction through the magnet of the motor, A.

The roller, H, with its mechanical pattern, the commutator, B, and the motor, A, constitute the important elements of the sending division of the instrument or apparatus.

The receiving division of the apparatus includes also the motor, A, and in addition thereto a disc, N, having in an annular series the several characters included within the scope of the instrument and mounted to rotate with the shaft, a, the motor to present the several characters during each revolution of the shaft in alinement with an opening in the end, o, of the opaque tubular casing, O. An opening in the opposite end, o', of the tubular casing admits light from a suitable source.

The casing, O, with its polariscope and helix, l, constitutes an electrically operated shutter for disclosing the particular character at the receiving station which may be selected by the commutator at the sending station, the movement of the disc, N, being made to harmonize with the movement of the commutator at the sending station to present that particular character opposite the shutter which corresponds to the contact point, $k\ k'\ k^2$, etc., on the commutator which is at that moment connected by the trailer with the inner ring, b^2, and hence with the main-line wire, L'.

The disclosed character at the receiving station may either be observed directly by the eye of the person receiving or the character may be photographed upon a sensitized film, q', in a dark chamber, q^2, the film being made to move step by step by means of a pawl and ratchet by the motor, A.

A TELEPHONE MAN'S TROUBLE.

The manager of a telephone exchange has many amusing and at the same time exasperating experiences during the discharge of his duties. Almost every day he is called upon by some subscriber, who reports that his telephone is out of whack, and then the manager or one of the telephone company's employés starts out looking for trouble. He doesn't

wear brass knuckles or carry a revolver, but he begins at the exchange and follows the wire along which the difficulty is supposed to exist, picking out his way through alleys, backyards, climbing fences and telegraph poles in his endeavor to find the trouble. After hours of time, the telephone man finds that the difficulty is in the subscriber's 'phone, and this, perhaps, caused by a thoughtless or careless act of some person. Manager Middleton, of the Merchants' Mutual Company, says that he has many times been called upon to locate trouble in some telephone, only to find that a hatpin, a watch, button hook, nail or some other metallic article had been carelessly placed on top of the telephone in such a manner as to connect the little nickel-plated posts and cut off the circuit, thus destroying the connection of the telephone with the exchange. Several instances of this kind have lately occurred and much trouble and delay resulted, which could easily have been prevented had the actions of metallic bodies coming in contact with two electrical poles, been understood or a little forethought used by telephone subscribers.—Michigan News.

PRIVATE TELEPHONE CONSTRUCTION.—I.

BY F. H. SMITH.

THE early private telephone outfits were made by beginners, installed by beginners, and cared for by beginners. As a person looks closely into the private telephone business at the present time, he can see plainly the results of the work of the amateur. It is time to call a halt, to cause the "genius" as he calls himself, to get conversant with the work so that he can do it properly. At a rapid pace some of the most expensive buildings in the country are getting cobwebbed. In some cases the wires are bundled in cables and the large cables run on hard finished ceilings; these ceilings were designed to be ever kept clear from such obstacles, so that they can be kept clean and free from vermin.

The contractor should go to work rightly and tell those for whom the work is to be done, that it costs money to do good work, show them how it should be done and tell them the reasons why. Any sane person will be convinced that he don't want loose, dirty wires on the floors or walls of a building if the thing is properly presented in the start. Most people like to see the wires at first and think they are a sort of an indication of some wonderful pieces of skill and work, but this notion wears off after a time and in most cases they have the work done over.

If the telephones are going into a wooden building arrangements should be made to have every wire concealed in the partitions, or if it is impossible to get inside a partition, to put the wires in a substantial moulding on the outside. Too much cannot be said against running common annunciator wire in bundles inside a partition. Rats and mice will eat off the insulation and then there is everlasting trouble. Put the wires into a tubing that cannot be eaten by the rats and mice, or, if the wires are used without the tubing, have an insulation that you are sure will not be destroyed, or nail the wires up separately. A person should not try to convince himself that rats and mice will not eat the insulation off paraffined wire. The writer has never seen any traces of rats eating the insulation off K. K. or rubber wires, and would be pleased to learn if others have ever had such insulation destroyed by such means. In such buildings as hospitals it seems criminal to run wires and tubing on the walls, but such is being done in some of the best buildings of this kind.

When the telephones are not scattered about much, No. 18 copper wire, B. & S. gauge can be used, or possibly a smaller size. If seven instruments were to be wired the eight wires could be run in a small channel cut in the wall; if the wires were covered with a thin layer of rubber and the rubber with a light braid, the whole bundle could be covered with a compound and the compound covered with the usual finish or with plaster of paris. Possibly to make a real good job a lead-covered cable would be best. The insulation on the wires in this case could be very light cotton, paraffined, and the lead need be but thin. The lead would make the most compact arrangement, and if it was lead cable that was run on the ceilings instead of dirty tubing, which it is impossible to get up neatly, the work could be done neater and the lead cover would be easily kept clean.

The factory with its unfinished walls seems like an easy place to run wires, but it is difficult to get in a telephone system, even in a factory, without much thought and care, if a good job is wanted. When annunciator wire is used every wire should be tacked up by itself and where the wires pass through the floor every one should have a separate hole. Never tack the wires close enough together so that metal double-pointed tacks can touch each other. Two wires should never be put under one metal staple or double-pointed tack.

When a factory building is new and the partitions and walls are clean, if the wires are well tacked to the woodwork and given a good coat of lead and oil, after once dry the wires are so well fastened that they can be swept over without disturbing them. In some places we see the wires run close together on small knobs; this is wrong unless it be a very damp or wet place. Through wet places the writer would recommend lead-covered cable, the cable to be covered with a molding unless well tucked away to prevent getting bruised.

When manufacturing buildings are separated some small distance apart, it is much better to use a piece of lead-covered cable to carry the circuits from building to building than to run the wires separate as so many wires side by side, even though they be small, make a hiding place for various things.

Where a combination of cable and open wires is used much care must be taken when the cable is feathered out not to leave the open end of the lead casing so that water can run into or moisture creep up into the cable as the wires are close together and the insulation very thin usually. Cover the end of the cable with some hot compound, having the cable quite warm, then bend it down, feather out the wires, and fasten each one to a small peg or tack it down firmly so that the wires cannot be moved where they come from the end of the lead casing. The end of the cable and the place where the wires are feathered out should be covered with a wooden block nicely fitted and the block screwed down tightly, especially on to the end of the lead cable to keep it from being moved about or pulled back from the wires that are fast. The permanency of the cable job depends very much on holding the ends of the cable firm. From the lower side of the block the wires can be spliced on to and continued through the building. As the wires are mostly inside of buildings there is no need of making provision for lightning arresters.

If the distance from building to building be more than a few feet, or so far that the cable cannot be supported from a 2 by 4 scantling by means of a piece of No. 14 K. K. wire wound around the two, a piece of cable similar to what the electric roads use for span wire, should be well fastened in one building and then pulled up tightly in the other and fastened; to this steel cable the lead cable can be secured by a No. 14 K. K. wire wound spirally full length of the span.

When it is decided to put the telephones in a factory, school building, etc., it is often a question whether to have a small central station, or to use the system in which each instrument is connected directly to a small board at every other instrument, so that a person at any one can call up another person at any other in the system without the use of a central.

The great trouble with the system with a central is that it often occurs that when a person wants to use the telephones there is no one at the switchboard. The writer knows of a high school building that cost about $125,000. The electrical devices are supposed to be the most convenient, but the telephone system is controlled by a switchboard in the office of the principal of the school. During school hours there is usually some person in the room where the switchboard is, but before and after school hours if the janitor wants to speak to some person that he may have working in some remote part of the building he has got to walk. This should not be. During the course of a short conversation the writer has seen the principal have to stop and answer a call at the switchboard. This is very nice at first, but a terrible nuisance after the novelty wears off.

Where buildings are scattered some 1,000 or 2,000 feet apart this system must be adopted if many telephones are used, but where the telephones are all in one building, the circuits not more than one thousand feet long the system with independent call is much the better.

In this article we will confine ourselves to the systems where no switchboard is used, or consider only the usual warehouse system, together with the system with two or more instruments on one circuit.

There are a number of firms, independent of the Bell Company, that are now manufacturing telephones that have had experience sufficient to enable them to make good apparatus. The instruments should be secured from reliable manufacturers or dealers; the transmitters should be carbon; the pattern with the granulated carbon seems to be the most popular; hence, in a commercial sense, it must be the best. Since there are no two people of the same height, and the instrument has got to be fastened to the wall, it should have an adjustable arm.

When the instrument is in place the mouthpiece should be at such a height that it is just midway between its highest and lowest position when in use by a person of medium height. If so placed the range of adjustment is sufficient to enable both the short and tall to use the telephone with comfort. No telephone job is a good one without the adjustable arm. It is very amusing to see a very short lady try to use

the average telephone; the same is true of the very tall man.

There are many telephones in use that have no battery box attached; this might do in some factories, but it seems like false economy to run an extra circuit for a battery, and the telephone is much harder to get connected with the line properly.

THE COUNTING AND CHARGING OF CABLE MESSAGES.

THE submarine cable companies of this city have issued some important information with regard to the rules which on and after July 1 will regulate the rules for counting and charging cable messages will be modified to meet the changes agreed upon by the International Telegraph Convention, held at Budapest, in 1896.

Messages may be written in plain language, code language or cipher language. Plain language offers an intelligible sense in one or several of the languages authorized for international telegraphic correspondence. In messages written entirely in plain language, the maximum length of a chargeable word is fixed at fifteen characters. Words of more than fifteen characters are charged at the rate of one word for every fifteen characters or fraction thereof.

Code language is formed of words of not more than ten characters taken from standard vocabularies of the English, French, German, Italian, Spanish, Portuguese, Dutch and Latin languages, or from the Official Vocabulary. In messages written partly or wholly in code language, the maximum length of a chargeable word is fixed at ten characters. Words of more than ten characters are charged at the rate of one word for every ten characters or fraction thereof.

Cipher language is formed exclusively of Arabic figures having a secret meaning. In messages composed of cipher language, every group of five figures or fraction thereof is charged as one word. Groups of more than five figures are charged at the rate of one word for every five figures or fraction thereof.

In messages written in plain language and cipher language, the words in the passages in plain language are charged at the rate of one word for every fifteen characters or fraction thereof; and the groups in the passages in cipher language at the rate of one word for every five figures or fraction thereof.

In messages written in plain language, code language and cipher language, the words in the passages in plain language and code language are charged at the rate of one word for every 10 characters or fraction thereof; and the groups in the passages in cipher language at the rate of one word for every five figures or fraction thereof.

Numbers expressed in figures are counted and charged at the rate of one word for every five figures or fraction thereof, each group being considered separately.

Trade-marks formed of letters are counted like figures, but when formed of letters and figures, the characters interrupt each other and are counted separately; example, a5c is counted as three chargeable words.

INDEPENDENT TELEPHONY FOR NEW ORLEANS.

A movement is actively afoot in New Orleans to organize a joint stock company to own and operate a new telephone exchange, and, judging from the fact that Mr. J. J. Fowler, late manager of the Great Southern, is interested and one of the prime movers in the new organization, it is expected that the project will be pushed forward with energy. The capital stock of the new company is fixed at $250,000, most of which will be subscribed for by local capitalists, but some of the stock will be floated in the North and East. It is the intention of the new company to have everything in readiness to perfect organization in the course of the next two weeks, and it is said that the initial meeting of the new company will be held before the 15th of July.

The new organization intends to, in the first place, reduce the price of the telephone service not only in private residences, but also in business houses, and to start in will fix upon a tariff of $30, and $50 per annum for telephones in dwellings and business houses, respectively. Each subscriber will be credited with 1,000 calls per year, and this number is deemed more than adequate to meet the demands of almost any residence or place of business. Snould, however, the 1,000 calls be exhausted before the end of the year the subscriber can, by payment of the original sum, receive 1,200 additional calls, and, if at the end of the year any of the calls should remain, they would be credited to tne ensuing year. In other words, say that 500 of the 1,000 calls remain at the end of the year, the subscriber would have to pay for only 500 calls the second year, which, in addition to the 500 calls remaining over from the first year, would entitle him to 1,000 calls the second year. This method would in a great measure do away with the indiscriminate use of the telephones by non-subscribers, and would tend to prevent in a great measure the frequent useless or unnecessary calls.

The company intend to use at once $125,000, on which to commence operations, leaving $125,000 in reserve. They intend to lay all their wires underground. Mr. Fowler, who has had great experience in telephone and telegraph construction, apprehends no difficulties whatsoever in placing the wires underground, and his velws are concurred in by the most experienced electricians and practical constructionists in the city. The new company intend to avail themselves of all the more recent and modern approved switchboards, appliances, telephones, etc., and expect to give the public a first-class service.

INDEPENDENT TELEPHONE LINES IN WISCONSIN.

While independent telephone toll lines, covering about 3,000 miles of line, have approached within forty miles of Minneapolis on the southwest, it is now announced that an independent company is planning to put independent exchanges in every town in northern Wisconsin, which has over 1,000 people. These towns will also be connected with long distance toll lines, which will reach from Minneapolis and St. Paul to Marquette, Mich. Among the towns which will be connected will be Eau Claire, Chippewa Falls, La Crosse, Winona, Wausau, Merrill, Bayfield, Ashland, Spooner, Stevens Point and their tributary towns. The work involves 200 local exchanges, 5,000 miles of toll lines and an expenditure of about $2,000,000. When completed, it is said, this system will be the most complete and extensive system of State toll lines in the country. If one of the independent companies now applying for a franchise in Minneapolis is allowed to put in an exchange it will connect with these toll lines. Leading Duluth and Superior capitalists are interested in the new company.

LOW RESISTANCE TELEGRAPH RELAYS.

AT the recent convention of the Railroad Telegraph Superintendents, the committee appointed at the last convention to conduct the low resistance relay experiments made its report through Mr. W. W. Ryder (C., B. & Q.). At last year's convention Mr. U. J. Fry (C., M. & St. P.) gave an account of some experiments he had made on his company's telegraph lines in the use of relays of low resistance (25 ohms) in place of the standard instruments (150 ohms each), and stated that the results were remarkable. With the low resistance instruments on wires that previously had had to be abandoned temporarily in stormy and wet weather there was now very little difficulty experienced, thus apparently indicating positive advantage in the use of the low resistance instrument. It was to investigate the subject further that this committee was appointed. The results of the committee's experiments during the year have been so conclusive as to leave no room for doubt.

Two lines of experiments were conducted, viz., the splitting of the coils of standard relays—that is, connecting the two magnets in parallel—and the use of low resistance, series wound, "pony" relays. The scheme of splitting the coils was tried on fifty-one circuits under the varying conditions of five railroads, and the results showed a decided improvement in service, especially in bad weather. The most marked improvement was obtained, however, with the use of a 25-ohm series wound relay. Lines equipped with these instruments work equally well in good or bad weather, as shown by the tests, and in every case the low resistance instrument worked much more satisfactorily than the one it replaced. Another important consideration in this connection is the fact that the battery power can be reduced in the same ratio as the instrument resistance, thus effecting a corresponding saving in battery material and maintenance costs. Telegraph engineers have always based their calculations on the old law that the combined resistance of the instruments on a wire should equal the resistance of the wire itself plus that of the battery. The committee's opinion is that this law never applied to telegraph circuits.

CITIZENS' TELEPHONE CO., Grand Rapids, Mich., an "independent" concern, reports 1,975 subscribers. It started last year with 500, and reports doing profitable business. It has 300 stockholders, 297 of whom live in the city.

ELECTRIC LIGHTING

THE HAMILTON, O., MUNICIPAL PLANT.

BY W. N. GRAY.

IN your issue of June 16, I notice a paper on "Municipal Lighting" by W. Worth Bean and feel that a few words should be said for the other side.

Mr. Bean's position is of course consistent if he is interested in the lighting business, and his paper was no doubt received with great satisfaction by his hearers, all of whom probably—if members of the National Association—would agree with him, and applaud his opinions. My objections to the paper are, however, that the arguments are too old; a good many of them beg the question, and then the writer is not at all sure of his facts.

While I have been in the electrical business for thirteen years and during that time have never advocated the operation of lighting plants by municipalities, and on some points agree with those who are opposed to such ownership, I have never been able to see that it was absolutely necessary that a municipal plant should be a failure, or that because city officials are usually corrupt, the people must therefore pay a profit to a corporation—often a foreign one—for what they can obtain at cost in another way.

Because some municipal plants have failed, proves nothing. How many private lighting companies have failed? Is it not possible that some of the municipal enterprises have been made to fail purposely through the insidious attacks of persons who, like Mr. Bean, are probably interested in seeing them fail, and through the constant, determined and very powerful efforts of the allied gas and electric light interests which are always on the alert to oppose city plants which may injure them. I have seen enough of the business to know that these interests will stop at nothing to prevent the success of municipal plants. And why should they? They are afraid of them, and when they assert that they will not succeed the "wish is father to the thought."

The stock argument against municipal ownership is that public officials are corrupt. Have you never heard of corruption in connection with a city lighting contract? When a town pays a lighting company $150 a year per lamp, or when there is competition and a contract is given to a company at $120, when there is a bid of $90, is it not safe to suppose that there is something in the transaction fully as unsavory as there could possibly be in the management of a plant by the same officials? As long as there are such things as city officials there will be corruption, and it seems to me that they might just as well work direct as to have the aid of a corporation, which aid in most cases simply increases the burden laid upon the people.

There is a great deal that is unjust, no doubt, in a city going into a business of this kind in competition with parties who are already in it, but I think if the facts were known it would appear that in a majority of cases the city plant was the outcome of the greed of the old company. Through manipulation of the officials and consequent large profits, corporations after a time begin to feel too secure, and act as if they "owned the town." They treat their customers with a scant courtesy; they hold up the city with outrageous lighting contracts; and then, when the people become roused and go into the business, they complain of what they have only brought upon themselves.

Now in regard to Mr. Bean's facts. I do not pretend to know the "inside" in regard to all of the plants he refers to—and he may be correct in regard to some of them; it would be strange if all of them were successful, and I will not make the mistake he does by referring to things I know nothing about. Mr. Bean is, however, unfortunate in referring to this city of Hamilton, and he is so far wrong in this case that a shadow of doubt is thrown upon all his assertions.

Through the pressure of the hard times of the last four years and the usual amount of bad management on the part of the Council—which can hardly be prevented in any town, and is chargeable to the people who elect them—the city finances have gotton into a tangled condition, and the revenue is not sufficient even for the legitimate expenses of the city. This has nothing whatever to do with the plant owned by the city. Municipal ownership has NOT cost Hamilton $575,000.

It is true that $625,000 has been spent for a water works, a gas works and an electric light plant, but I venture to say that no one in Hamilton except the owners of the private gas works would say that this money was lost, or that municipal ownership has "cost" the city this amount. It is NOT reported that an order is made to discontinue the light for lack of funds.

Last December, due to lack of cash, there was some trouble of this kind, but if the city had been lighted by contract it would have been just the same unless the contractor had been willing to wait six months for his money. Hamilton has NOT had an expensive experience in this direction, and the "taxpayer who has burned nothing but oil is NOT now helping to pay the bill."

I will show why:—In the first place $350,000 of the $625,000 referred to was spent for a water works, so that the large sum mentioned by Mr. Bean was not all sunk in a lighting plant, as one would suppose, and in this connection let me say that one of the most peculiar features of these attacks on municipal plants is the fact that water works are usually excepted.

People who will cry down lighting plants and talk about confiscation and robbery, etc., generally seem to think that the supplying of water is a legitimate business for a city to engage in and that it can be done honestly, too.

The water works in Hamilton are operated by Trustees; water is supplied for ALL city purposes free; the rates to private consumers are much lower than the average in towns of the same size, and not only are all expenses paid, but all extensions, interest on bonds, and some of the bonds themselves have been paid. Of the gas works and electric light plant I can speak more specifically: They are both fine pieces of property and are managed successfully by one Board of Trustees.

Twenty-five years ago the people of Hamilton paid $4 per 1,000 feet for gas; by hard work and long continued efforts they managed to get the price down to $2. While in other towns of the same size gas was being sold for from 80 cents to $1.50, the local company refused to reduce the price from $2, saying they would lose money if they did. The city then built gas works, put the price of gas at $1 and lighted the streets at about one-half the former cost. The gas company met the price and proved the falsity of their former claim by making a profit.

About two years ago the city built an electric lighting plant; whether it was a necessity or whether it was a wise thing to do, has little to do with the question. The people wanted electric light and were willing to pay for it, and they got it. The plant is large and rather elaborate and probably cost a little more than it would if it had been built by private parties. There is no doubt that before its acceptance it was run rather loosely, and like most new things took a little time to settle down and get into good running order, but it can not be said that it has ever lost money because the plant is operated principally for street lighting, and it has cost no more to light the streets than it should. The streets of Hamilton are lighted by 210 arc lamps and about 300 gas posts, and the allowance made the Trustees by Council is about $2,000 more per year (the city having a population of 25,000) than was paid the gas company ten years ago for less than 600 gas posts, the city then having a population of about 15,000.

Does this seem very bad for the taxpayers, the people who "burn oil?" Gas is supplied to private consumers at 80 cents per 1,000 feet, and the result is that the families who would probably be burning oil if the city had not built the works number about 2,200, 1,600 of whom are supplied by the city. Do you suppose that gas would be sold at less than $2 or that there would be over 1,000 gas consumers in the town if the city had not built these works?

The electric light plant furnishes 210 arc lamps for the streets, and the Trustees are allowed by Council per year per lamp for all-night service; current is sold to private consumers (metered) at 8 cents per kilowatt-hour (the prevailing rate in neighboring towns being 15 cents), and there are 3,000 lamps connected to the system. At these prices and with the worst kind of competition from the gas company (who are doing about one-fourth of the business) both of the plants are earning considerably more than their running expenses; in fact the plants are kept in good order, are continually making extensions, and are more than earning the interest on the bonds. If these plants were doing the entire business of the city they would be creating a sinking fund, but there are always some people who are susceptible to influences of various kinds, and the gas company do their share of the business, and work against the city, make charges against the plant and its managers which they cannot sustain, and then claim that city plants do not pay.

If it was a fact that these plants did not pay it would be the fault of the people who own them, and the very people who have the most to say about municipal plants losing

money are the people who aid the opposition with their patronage.

SOME THINGS ABOUT WIRING AND WIREMEN.—II.

BY S. H. SHARPSTEEN.

IN appearance the wiring inside the building should resemble Fig. 3. On leaving the main block, A, which is provided in all cases with a cover when not placed in a cabinet, the entrance switch, B, comes next; this should be some good make of knife switch and should open downward as illustrated in Fig. 3. It should be a knife switch for three reasons. The first is that a knife switch shows plainly that the circuit is open or closed. Second—It makes, or should make, a big break in both sides of the circuit, so that in case of a bad cross inside the house and current passing from high pressure mains the trouble could be remedied by opening this main switch. Third—During a bad thunder storm the knife switch of proper break can be opened and save the cracking on combination fixtures that is common in some places and unpopular with nervous people. The entrance switch should always be left open when people leave their homes for any length of time.

As seen in Fig. 3, the next thing we encounter is the meter, C. A meter loop should always be provided for in wiring a building. In many cases it might be advisable to have the meter on the floor below to save the meter man the trouble of entering the attic.

After leaving the meter comes the question of risers or mains. The wires pass down the gable end of the attic to the floor joist and through under the floor, if there be one, to a convenient place to go down to the floor below.

At this juncture we have to determine the size of wire for

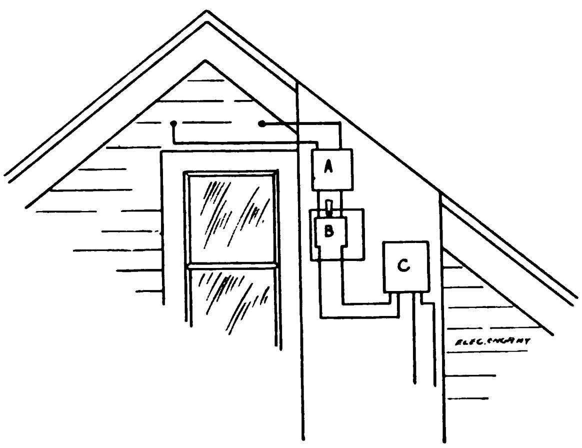


FIG. 3.

our mains. Some wiremen would conclude that all the lamps would never be burned at one time, and would commence by putting in a small main to start with; this the underwriters will not allow and it is poor practice, let it be where it may; it has cost much trouble in the past. We will decide on a No. 1 wire, B. & S. gauge, stranded, rubber-covered.

The matter of insulation will depend much upon what the underwriters may demand. In New York State rubber-covered wire must be used for concealed work, but just over the line in Pennsylvania K. K. or fire and weather-proof is used and allowed by the fire underwriters' inspector. If the floor joists run parallel with our wires we fasten one wire to one floor joist and the other wire to the next, having one floor joint between the wires. Knobs should be large enough so that the wire can be drawn up tightly and tied firmly.

If the wire has got to pass through the floor joist then the conditions are much different. Holes should be bored through them about 12 inches apart, porcelain tubes put in, and the wire run through the tubes. One of the first things that some people will think of when they see men running wire is, to saw a slot in the floor joist and lay the tubes and wire in that. Such practice weakens the floor joist very much if the wire is large, and if the wire is too close to the floor the carpenters are apt to drive nails into it. If the holes are bored in the usual way with bit and angle brace there will be some slope to the hole. The tube should be a good close fit in the hole, and the head of the tube should be on the high side, to keep it from working out with the jar of the building.

The mains should pass down through to the second floor in some place selected by the architect or owner, that will be convenient for a cabinet in which to put fuses to control the various circuits of the house.

Usually the mains would end at the fuse cabinet, and a branch run into the cellar for the lamps there, but in a city of any size the proper thing to do is to extend the mains into the cellar; then in case the street wiring should be put underground the house will not have to be torn up to get the proper connection with the street. In course of erection it is a small job to put in these extra wires and the expense of getting them in after the building is finished would be very much more.

ELECTRICAL CENTRAL STATION ECONOMIES.

BY I. H. BABCOCK.

THE business of the central station manager is, not only to "keep the wheels moving," but out of the material furnished him to develop results which will pay the investor a fair income upon the capital invested. If he cannot do this, either the enterprise with which he is connected is unworthy of prosecution, or else he is lacking in the skill and ability to utilize the elements of profit which are in the materials placed at his disposal. To throw away products which can be turned to profitable account and made to pay dividends is an evidence of lack of thrift which admits of no palliation. When we come suddenly from darkness into the light of day, we are partially blinded, and this seems to be the case to some extent in the electrical enterprises. There has been a sudden and wonderful development in this line, millions of dollars have been invested, and thousands of our brightest young men have enlisted to conduct the business affairs of these corporations. This development has been so rapid that many seem to be in a sort of maze, and have not yet taken a comprehensive view of the situation that surrounds them. The manager of an electric lighting company who possesses the technical skill to produce the most perfect light and yet has not the business ability to turn his waste products to practical account, cannot be said to worthily fill the position he occupies. He must look beyond the mere production of a dazzling light, however pleasant and attractive that may be. In Mr. T. C. Martin's very able paper read before the National Electric Light Association at Niagara Falls in June, he remarks, "It is as apparently true to-day as when the association was formed that the companies restrict themselves injuriously in their natural and logical advance by remaining mere lighting corporations." By so doing they are only doing business between dusk and daylight, and are standing idle all the rest of the time. Continuous work is necessary for the greatest success. Interest charges go on just the same if machinery and capital are idle more than one-half of the time. Mr. Martin further says: "We are led to believe that the isolated plants are the real backbone of the electrical power industry to-day. Why this is so it is difficult to explain, except on the hypothesis that station current when obtainable often costs too much, and is generally not obtainable." How then can we have continuous work, and how can we supply current at a profit, and yet so cheap that it will be called for in outside power work? I answer, by utilizing the by-product of exhaust steam, and making the lighting station a heating and power station as well. This added profit will enable the manager to increase his day work at a lower price. The more day work, the more steam produced, until soon the station is carrying a fair load at a profit during the entire twenty-four hours. Heat is as staple an article for eight months of the year as light. This proposition is neither a theory nor an experiment, as some of the more far seeing are doing this already with great success. Many managers sell exhaust steam enough to more than pay all fuel bills at the station. One manager states that while making no money in lighting, he yet pays 8 per cent. dividends on the entire capitalization for electric and steam plant out of the income from exhaust steam heating. The same thing holds good in street railway work. Resources and liabilities bear the same relation in electrical operations as in any other. The fuel bill at the station creates a liability, but when it evaporates a certain amount of water into steam, that becomes a resource. How shall this be turned to practical account, so as to put the most money in the treasury? The engine utilizes about 10 per cent. of the steam produced. When the remaining 90 per cent. is allowed to escape into the air it is a waste of resources, and if this policy is carried far enough it leads to insolvency. The gas companies, as competitors in lighting, maintain their ground by selling everything produced that has a value. When the electric light companies do the same thing they will have established themselves more firmly than ever in the field now occupied by them.

SHOULD GENERATING PLANT BE MOUNTED ON SPRINGS?[1]

BY JAMES SWINBURNE.

THIS is really part of a larger question: Should moving machinery be mounted on springs? The question concerns both the health of the moving machinery and of the people who may be moved by it. In central stations and in passenger steamers the shaking caused by machinery is most serious. In flour mills, for example, it is rather a question concerning the gear itself.

If we consider, say, a direct acting pump in space, it is a system that, of course cannot move its center of gravity as a whole. If then its pistons and plunger move in one direction the rest must move in another direction, the distance depending on their masses. Any imperfectly balanced machinery must, therefore, move its bed plate if freely suspended. A perfectly balanced engine is thus an engine whose center of gravity never varies relatively to its bed plate. This definition is really too small, because a moving system, such, for instance, as two cranks at 120 degs. on opposite ends of a shaft, do not change their center of gravity, but give the bed plate a rocking but non-translational movement. A gas engine with a flywheel similarly tends to rotate its bed plate at each impulse round an axis parallel to that of the shaft. A balanced engine is, therefore, really one which does not move its bed plate if freely suspended. Such an engine is practically never realized.

When an engineer sees an engine bed plate moving his first instinct is to bolt it down; it then moves a little less, but still moves, and he has a sort of feeling it must shake itself to pieces if allowed to move. Bolting down an engine to a bed of concrete is merely increasing the size of its effective bed plate, but the whole bed plate, including the concrete, must now be moved. It rests on the earth, moves slightly and communicates vibration to neighbors who are longing to be compensated for disturbance. Sometimes the concrete bed plate is isolated by mounting it on felt; that means that the larger bed plate is mounted on rather imperfect springs. A rather striking case is that of church bells. Bells are very much out of balance and the bed plates are mere cages of timber, so the bed plates would tend to move a good deal. The bell people do not like to see it move, so they wedge it to the steeple, and the result is a cracked steeple. The consequence is that you often hear that such a church has a very fine peal of bells, but they cannot be used, as the steeple will not stand it. Though this may be a relief to people whose ears are in tune, it might be cheaper not to make bells than to make them and hang them so that they cannot be used.

The question is, if the bed plate of an engine wants to move, why should it not have free play? As far as the engine goes, a little thought will show that all parts are subjected to smaller stresses if the bed plate is free to move. An engine will, therefore, wear longer if it is allowed to move its bed plate. As to the foundations, if the bed plate is allowed to move no foundations to speak of are needed, and there is no vibration communicated to the ground. The writer has tried this arrangement on a small scale. There is a small dynamotor on one of the top floors of Mr. Crookes' house which is very much out of balance and rendered the house uninhabitable at first. It is now on springs and makes no noise. There is also a dynamotor for electrolytic work in the writer's laboratory. It is on springs and no one has any inkling of a chance of complaining.

In passenger steamers the throb of the engine is exceedingly unpleasant—in fact, many people would rather go by a slower boat than travel 21 knots and be at the same time shaken 42 more knots by his pedometer. Mounting marine engines on springs seems rather a bold suggestion, and perhaps we ought not to begin there. The moving systems are so heavy in proportion to the fixed (or "attached" is the better word), that the marine engine is a particularly difficult case.

STEALING COLORED ELECTRIC GLOBES.

A dispatch from Oakland, Cal., of June 22, says: The beautiful colored globes for the electric lights in the grounds of A. Schilling, corner of Nineteenth and Jackson streets, have been stolen by the hundreds. The grounds have been open to the public heretofore and have been visited by a great many people, but if this vandalism continues they will be closed.

BROKEN GLASS.—An electric lighting company in New England was notified recently by the city authorities to remove from the streets broken glass falling out of its globes. The glass is a menace to horses and bicyclists, and there is an ordinance against letting it be scattered on the roadways.

[1]Abstract of a paper read before the Inst. of Civil Engr's.

WHAT ELECTRICAL ENERGY COSTS.—I.

BY ALBERT B. HERRICK.

THE cost of production of electrical energy is that value at which the whole output of the plant could be sold continuously, under the conditions of actual demand without a profit or without a loss. This statement is apparently controverted by the array of statistics involving all possible partial combinations of the items entering into a true cost; these published statistics form a disjointed, inconsistent mass of figures which cannot be analyzed with any result as to the legitimate cost of output, and each statement is a separate mystery as to what was charged against current production, as many items rightly belonging to this cost were relegated to other accounts.

These varied costs have common characteristics, which indicate what their probable function would be. The promoter's cost is an estimate of what the energy produced might cost, and includes generally an underestimate of development, investment and operating expenses. Fixed charges and depreciation are in many instances conspicuous by their absence; an overestimated demand, and the resultant combination of figures show a highly profitable undertaking. According to two well known writers, Niagara, three years ago, was to reach Albany, N. Y., 330 miles, with power at $22 per h. p. year; to-day, Buffalo, 15 miles from Niagara, is supplied at a figure near $30 per h. p. year.

Costs bear on their face an appearance of veracity which is not as a rule maintained on closer inspection, besides lacking items of actual expenditures for a given production. Neither the gross output nor the load factor is given, which have direct bearing on the costs cited. Such costs, when published, have a very bad effect on the electric lighting business, and establish precedents as to the cost of production which cannot be upheld in practice, and yet are not readily disproved.

These so-called costs operate in preliminary basic estimates as follows: A new station wishes to estimate the cost of producing current; operators of plants of a similar character are questioned; a certain plant, B, is generally selected as approximating to conditions of A's prospects, but A can condense, has free water and lower taxes than the selected case, and A's values are reduced to accommodate these improved conditions of operation. Yet it is overlooked that B supplies a class of customers who give him a load factor which allows him to capitalize for less per unit output, and which will more than offset in reduced fixed charges, any internal improvements of A. In this way A's price is based on the false assumption that they are analogous plants.

Then again, there are essential expenditures omitted or divorced from the costs which are necessary elements, even such charges as interest on plant, depreciation and unproductive labor; or labor and supplies required on repairs are charged to construction accounts. The construction and miscellaneous accounts seem to be flexible enough to include any charges the exact location of which is doubtful, and this doubt only arises from not having clearly before the mind that which constitutes a cost. It is these costs that are disturbing legitimate lighting and power industries, and the showing made by them establishes competitive electric light and power plants, and is the element which results in financial disaster.

The cost of power, developed in power houses for electric railway purposes is published for obvious reasons, and in a number of cases the items essential to the maintenance of the investment or returns on capital so invested, are disregarded; yet, why they do not enter into a statement of costs, is beyond explanation. In the upbuilding of any plant these charges are a more inflexible and inseparable part of the investment than the items usually added together and presented for consideration as a cost—labor, plus supplies, plus coal, plus repairs. All of the latter charges cease when the plant shuts down or is abandoned, yet the fixed interest charges are maintained against this investment as long as it exists, and these charges are disregarded as a functional part of the cost of output of the plant, and as long as their introduction in power costs are withheld, the value of the engineering feature in power plants, and its true worth, will be unknown to the art.

It must be said in defense of these various methods of arriving at partial power production costs, that they have a long list of lineal descendants as references for this practice; nevertheless, the perpetuation of an established wrong will not relieve the conditions which false costs have brought about in the electric current production industry of to-day.

These partial costs, among other things, have been used for the establishment of power plants for railways which have

been buying their power; through this medium of flexible costs a showing can be made that any railway can make power cheaper than it can buy it. There are several causes for this method of financiering, such as to secure the contract for the installation, to sell apparatus, and it may even come from within the company, as the plant extension may redound to somebody's advantage. Some recently published so-called power costs have several essentials missing, such as interest, fixed charges, taxes and insurance, all of which ought to be included in a true cost.

As to the effect on existing companies, of competitors with new and improved apparatus, there need be no uneasiness engendered so far as the electrical end of the plant is concerned; the gross gain in all electrical improvements instituted in the past seven years will not aggregate one-tenth of the gain, which would result, if the losses in the steam, operating in the engine cylinder were reduced one-quarter, and which can be effected by properly proportioning units to the output.

Viewing these railway figures for cost of power from another standpoint, some extraordinary results are arrived at in this way: The ampere meter, sometimes an old type, not within 10 per cent. of accuracy, is read half hourly! As a result of a number of tests, the reader of fluctuating currents will naturally take a higher, rather than a mean reading, and multiplying this again by normal voltage of dynamos will obtain the watts. The result of this method of taking power output is from 40 to 60 per cent. in excess of the reading of an integrating wattmeter, and consequently with the output determined in this way, and divided into the gross cost, a much lower cost per unit is obtained.

The street railway business has inherited from its predecessor the steam road, the "car mile" basis for figuring cost of transportation, and power stations are even to-day required to sell their product by the number of miles they propel the cars. Grades, weight of car, speed, controller, traffic density, track construction, line losses, motormen, are all variables which have to be considered if the results of different roads are being compared; hence, with the "car mile" basis for power cost of railways, there can be no comparable data.

The cost obtained by municipalities who contemplate doing their own illumination, is generally arrived at with such notorious disregard of general principles, as not to require serious consideration; besides, their political bearing, so obvious in many cases. Yet they are very hard to controvert, and they tend to establish a price, and their publication can only injure and menace established legitimate lighting industries. Matters have come to such a pass that conservative lighting companies are arranging for other business, so that they can lose or hold their city lighting, which source of revenue depends largely upon which way the wheels turn, as they do not care to depend upon such hazardous loads for fixed income.

Naturally this matter of cost is coming more to the front, as it is the all important element in financiering new plants, and as the most lucrative locations for electric light or power production are occupied, the true cost is becoming more and more bereft of elements which it should bear, so that the resultant figuring will show a comfortable profit and attract the unwary investor. The result is that the investing public to-day, looks at established electrical development investments with suspicion, and it has a just cause, and will continue to do so until the returns on the investments are figured on a legitimate basis.

These published costs act on every hand to the detriment of legitimate electric distributing enterprises. The large customers, by comparing their costs of current supply bills with some costs of current production, get the idea that their bills are too large. This false conclusion fosters the isolated plant idea, which is the worst thing that can happen to both parties and legitimate business, and false costs have again to be harmonized. The central station manager will probably recognize some of his troubles depicted in the above, as they are taken from actual examples met with by clients of the author.

Having now exposed the operation of the present usual method of determining cost, the writer will attempt to enunciate a proper system of making up costs. This is not a matter of bookkeeping solely; it includes largely common-sense, and any set of books can be analyzed where all expenditures are noted, and a true cost arrived at.

ST. PAUL, MINN.—The Board of Control has awarded the contracts for engines, dynamos and wiring for the new city and county hospital to Jas. G. Robertson, representing the Ideal Engine Company, of Springfield, Ill., for the engine; to the Western Electric Company, of Chicago, for the dynamo, and John A. Gorman, of St. Paul, for the wiring contract.

THE SPECTROPHOTOMETRY OF INCANDESCENT LAMPS.

BY W. R. TURNBULL.

IN the January 1, 1896, number of The Electrical Engineer, Dr. W. H. Birchmore published an article on "The Mistaken Ideal of Artificial Light Improvers." His curves are plotted from, and his paper is based on, a table of mistakes which unfortunately appears in Palaz's excellent book on "Industrial Photometry."

This table purports to come from O. E. Meyer, but the Beiblaetter reference[1] to Meyer's article gives tables which are, in main essentials, the same as the tables of other investigators. Apparently Palaz, in copying Meyer's table, did not give sufficient attention to having the ratios right, and therefore, the table gives, for the most part, the reciprocals of the proper values: e. g., Palaz gives $\frac{\text{Sunlight}}{\text{Gaslight}} = 4.07$ at the "B" line, whereas Meyer gives $\frac{\text{Gaslight}}{\text{Sunlight}} = 4.07$.

The result is that the entire table is a mistake, through which he attributes a large amount of blue rays to incandescent lamps, and it is surprising that Dr. Birchmore did not compare such startling results with the work of others, for to a worker along these lines, the error is apparent.

In aiming to improve our light sources, we should indeed take sunshine as the ideal and normal light, but the combined work of Schumann, Meyer, Vierordt, Nichols, Franklin and others shows that our artificial sources are weak, not strong, in violet rays and they are strong, not weak, in red rays. There is, therefore, no mistaken ideal in attempting to get higher percentage of blue rays in our artificial lights, for we need them.

Had this mistaken table been quoted by one writer alone, it would hardly have been necessary to call attention to it, but again, and more recently[2], it has been made use of by Mr. M. A. Edson in an article on "Vacuum Tube Lighting." In the context of this table (which is transformed into percentages) he says, "As is well known violet light should be avoided."

How has this become "well known" when it is in direct variance with the results of all workers who have studied the matter thoroughly? It is true that a violet light is to be avoided, just as a red light or a green light is to be avoided, but a light with its proper proportions of violet light, as determined by our natural illuminant, the sun, is to be desired and not avoided. The light from vacuum tubes often has a preponderance of violet and ultra-violet rays, but this is not always the case, for a tube containing traces of hydrogen gives a bright red light, one containing nitrogen, a purple light, and so on. It is probable that if vacuum tubes were filled with proper proportions of several different gases, before exhaustion, that the remaining traces of the gases would give to the light the proper proportions of all rays from red to violet.

I am sorry to have to speak so critically of the two articles above cited, but it is time that our inventors and engineers were helped by the investigations of physicists, who have studied the subject, and not misled and confused by articles which, were the tables on which they are based, corrected, would disprove just what the writers attempt to prove.

The following curves give the results obtained by Nichols and Franklin[3] and by Schumann[4] in extended studies of the incandescent lamp. Their results are in good accord with those of other investigators and may be considered typical.

Fig. 1 shows the proportion of colored rays in different sources of light; the light from a 16 candle-power Edison lamp (operating at normal candle-power) being taken as a standard of comparison and all of the sources being made equal to unity in the yellow region of the spectrum (at the "D" line). It is obviously necessary to reduce the intensity of the light from different sources to unity at some point (e. g., the "D" line), since we are only concerned with proportions of colors and could make no measurements, that would mean anything, by comparing the total brightness from sources such as the sun and any artificial light.

No. 1 is the curve for daylight, when the sky is clear, and it shows in a most marked manner how very intense the blue end of the spectrum is in comparison with the incandescent lamp (V) and with other artificial sources such as the arc light (III) and lime light (IV); although in the case of the arc light there is one region, in the violet, where the radiation is

[4] Proc. Amer. Ass. for the Adv. of Sci., August, 1888.

unusually intense. Curve II shows that with a clouded sky, daylight is not so predominatingly strong in blue rays,

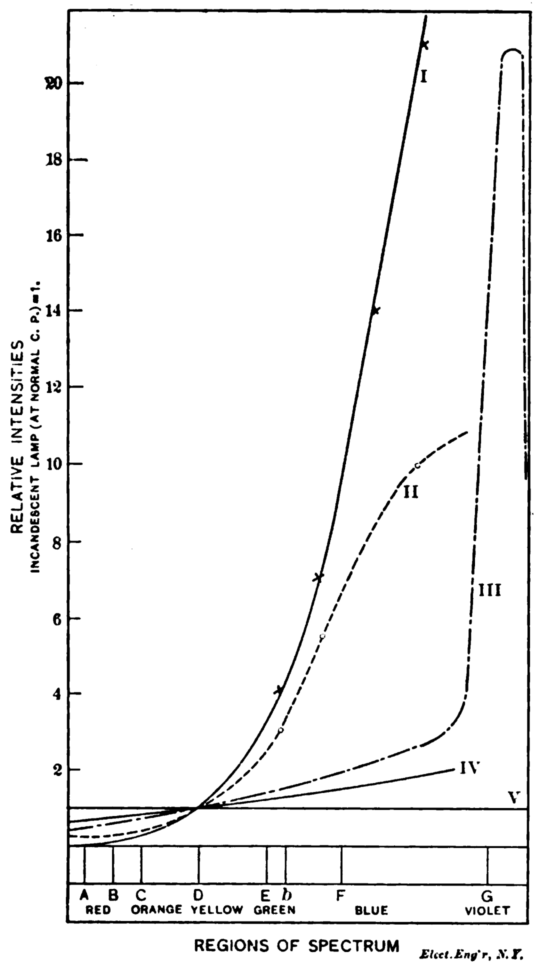

FIG. 1.—CURVES SHOWING PROPORTIONS OF COLORED RAYS IN DIFFERENT SOURCES OF LIGHT.—I. DAYLIGHT (Clear); II. DAYLIGHT (Clouded); III. ARC LIGHT; IV. LIME LIGHT; V. INCANDESCENT LAMP (Nichols & Franklin).

although it still shows itself much stronger than most artificial sources. Were curves for petroleum and gas plotted on Fig.

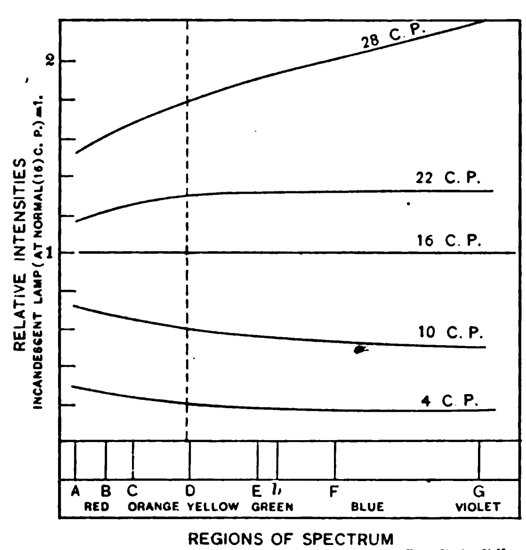

FIG. 2.—PROPORTIONS OF COLORED RAYS IN LIGHT FROM AN INCANDESCENT LAMP AT DIFFERENT CANDLE POWERS. (Nichols & Franklin).

1, they would be a little above curve (V) at the red end of the spectrum and somewhat below it at the violet end.

Fig. 2 shows curves for a 16 candle-power Edison lamp operated at the abnormally low candle-powers of 22 and 28, and at the abnormally low candle-powers of 10 and 4. It will be noted that at the red end of the spectrum the intensity increases more slowly than candle-power, and at the violet end the intensity increases more rapidly than candle-power. There

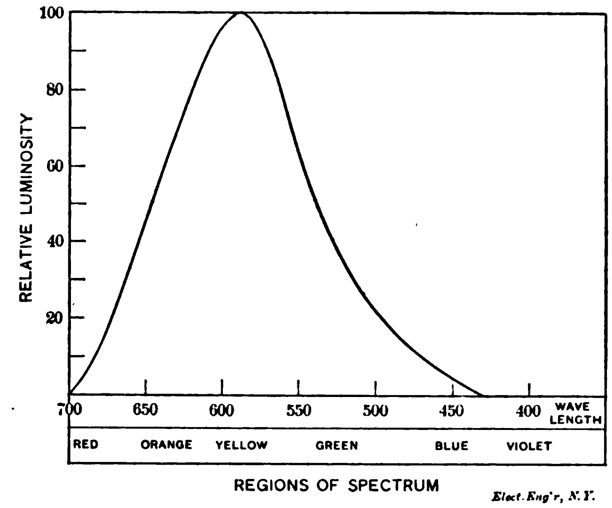

FIG. 3.—LUMINOSITY OF INCANDESCENT LAMP (Ferry).

is an intermediate region in which the intensity is proportional to candle-power and the dotted line in the figure shows at what position this holds true; it is in the yellow, very near the "D" line.

It is to be hoped that in considering Fig. 1, no confusion with luminosity will arise. The curves of Fig. 1 simply give comparative values for the intensities of different sources in

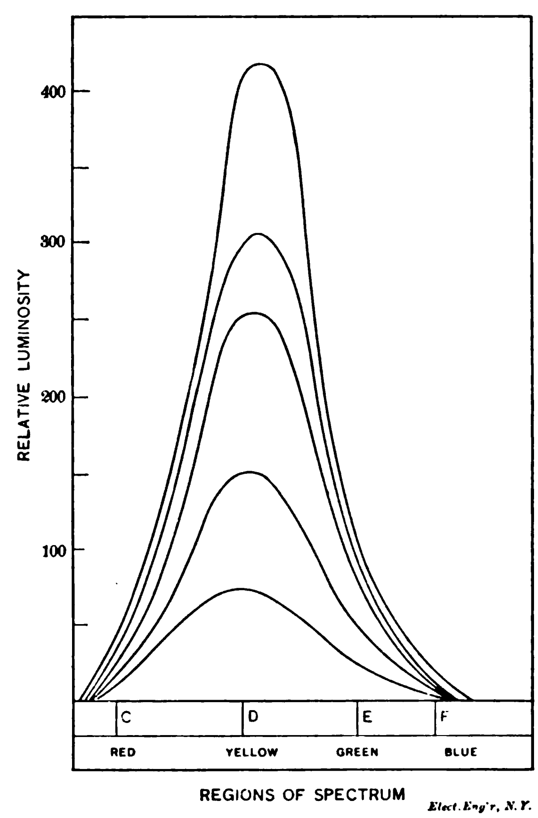

FIG. 4.—LUMINOSITY OF INCANDESCENT LAMP OPERATED AT DIFFERENT EFFICIENCIES (Schumann.)

different regions of the spectrum, when these sources are compared with a 16 candle-power lamp and when the intensities at the "D" line have previously been made equal. For example, No. 1 shows that sunlight, in the blue region, is proportionately 20 times brighter than the light from the incandescent lamp in the same region, and so on, but it tells nothing of the luminosity of a single source for any region

of the spectrum and it gives no comparisons of luminosities for different sources.

Information of this kind can only be obtained from such a curve as that shown in Fig. 3, which is the luminosity curve of an incandescent lamp at normal activity. This curve shows to what extent the different colored rays, making up its light, contribute to the light-giving power of the source.

Luminosity curves may be plotted in several ways, but the most usual one is to hold a book (one that necessitates reading, not inference, such as a table of logarithms) in the different parts of the spectrum and regulate the intensity of the light until one is just able to read the print at a fixed distance. Holding the book first in the red, then in the orange, and so on, the light will, in general, be decreased until the yellow is passed when it will have to be increased as we approach and enter the green, blue and violet. The inverse of the values thus obtained for intensity of the source, when different parts of the spectrum are considered, are then plotted as ordinates (the maximum luminosity being called equal to 100) and the regions of the spectrum are made the abscissæ.

This curve of Fig. 3 is similar in form to curves for most other sources of light having a complete spectrum, but it is, of course, not identical with these and for the incandescent lamp itself, the luminosity curve changes in magnitude and form as the watts per candle change. (See Fig. 4, from Otto Schumann's results[5].) The lowest of these curves is that for a lamp operated at a low efficiency, and the highest of them is for the same lamp at a much higher efficiency. Luminosity curves of all sources, that emit a complete spectrum from red to violet, must be similar in general form, from the very nature of our organ of vision with its limitations beyond both ends of the visible spectrum.

An examination of these curves shows that one ought to manufacture yellow light in order to obtain maximum efficiency, for yellow light gives a maximum return for the energy expended, but at the same time it is obviously necessary, for the health of our eyes, to have a light with the proper proportions of all rays in it, and no one, for instance, would advocate the use of the sodium light by which to read.

"The most important wave lengths, so far as light-giving power is concerned, are those which form the yellow of the spectrum, and the relative luminosity falls off rapidly both towards the red and the violet. The longer waves have, however, much more influence upon the candle-power than the more refrangible rays, as will be seen by an inspection of the curves Fig. 4, the relative falling off of the red end of the spectrum being compensated by larger and larger accessions in the blue and violet as the state of incandescence increases.

"Luminosity is the factor which we must take into account in seeking a complete expression for the efficiency of any source of illumination, and the method to be pursued in the determination of luminosity must depend upon the use to which the light is applied. If we estimate light by its power of bringing out the colors of natural objects, the value which we place upon the blue and violet rays must be very different from that which would be ascribed to them, if we consider merely its power of illumination as applied to black and white. In a picture gallery, for instance, or upon the stage, the value of an illuminant increases with the temperature of the incandescent material out of all proportions to the candle-power, whereas, candle-power affords an excellent measure of the light to be used in a reading room[6]."

It is not my object to go further into this subject at present; this paper simply strives to correct a mistake which already has become far too wide-spread, and if it serves to make matters at all clearer regarding both the composition of the light from different sources and the meaning of the term "luminosity," it will have served its end.

NIAGARA POWER IN BUFFALO GRAIN ELEVATORS.

Not only will one elevator in Buffalo use Niagara power to handle grain, etc., but two of these great structures in the Queen City will use the transmitted energy to operate their machinery. The latest to announce their intention to avail themselves of the power is the Electric Elevator Company, whose elevator building is now going up on Buffalo Creek. They will take 450 horse-power, and the motors have been ordered. Electricity is popular with elevator establishments because it is less likely to create fires than power generated on the premises.

THE HISTORY OF AN X-RAY BURN.

BY S. H. SHARPSTEEN.

An account of the X-ray trouble I have had may be of interest to the readers of The Engineer. During the latter part of December, 1896, I was experimenting to find the best position of the body in relation to tube and plate in order to get a picture of the hip joint. There was a young man in the shop who used to help me with that work, and I had him lie on a table back down, with clothes all on. I placed the tube over the body near the point where the abdomen wall joins the leg. The tube was large size, double focusing, current high frequency; the small anti-cathodes in the tube were of platinum. Most of the time anti-cathodes were at low red heat. The anti-cathodes were about 6 inches from the body or skin. The exposure was about twenty minutes. The plate was not affected much, and I could not see the outline of the bone.

After about ten days the young man's leg became sore, the skin came off, and a physician was called. Our company also had a physician see the boy. Our physician thought that the wound was commencing to heal and that the young man would soon be out to his work. During this time he used to take a car near his home and go to see his physician. About a month from the time the young man's leg began troubling him he was in the shop and expected soon to go to work, but the next thing we heard was that the flesh had died to a depth of about ⅛th of an inch and about 1½ inches in diameter. At this writing, June 2, 1897, the young man is still in the house with the wound as large as a silver half dollar.

About a week after the young man was exposed I exposed my wife, same set, same place exposed, same tube, time of exposure about thirty minutes. After ten days the skin turned a dark red color and commenced coming off. Carbolic salve was applied for a time, and later a physician was called. By this time the wound was sloughing serum and the doctor had Squibs' sub-nitrate of bismuth put on it occasionally as part of the dressing, the other part was vaseline and carbolic acid. The sloughing was checked some, and soon the wound appeared to get better. Size of wound about 1½ inches in diameter. After about three weeks the skin stopped growing, sloughing had ceased, wound commenced to get inflamed; the bismuth had formed a thin layer over the wound up to which the skin had grown.

At this time the physician dug off the layer of bismuth; the nerve action seemed all right as the whole procedure of removing the bismuth was painful; the circulation was there as the wound bled during the removal of the bismuth. This was about seven weeks from time of exposure and flesh was not dead yet, but one week from this time there seemed to be a layer of dead tissues and in about two weeks this tissue was as dead and tough as a piece of sole leather and as large as the original wound.

The doctor treated the wound with proto-nuclein after the removal of the bismuth, leg swelled and became inflamed and patient was compelled to take to her bed; until this time she had been about the house during the day, bending slightly to favor the wound when she walked.

At this juncture I took my wife to the Post-Graduate Hospital, New York, and left her under the treatment of Dr. Seneca D. Powell. After about twelve days of hot carbolic applications the inflammation and swelling were diminished very much, and Dr. Powell dissected out the ulcer and left a place about 4 inches long by 3 wide, and in some places it was over an inch in depth. Almost immediately the flesh commenced filling up where it had been cut away and now, six weeks from time of operation, the wound is nicely filled in.

There are several things to be considered.

I don't think that the X-rays had anything to do with affecting the flesh as a long exposure with an abundance of rays passing through the body at 2 feet distance from tube will not affect the tissues in a harmful way. A person can get a good bright screen 10 feet from tube, but cannot detect any sensation upon the softest tissue in the body, whereas if he gets closer to the tube there is a decided sensation. If the X-rays are harmful to the flesh why will they not affect it, regardless of distance from the tube, as long as they are present in abundance?

1. After careful consideration I am of the opinion that the harmful effect comes from the pulsating current passing

through the flesh outside the tube. It seems reasonable to think that under so high a pressure the pulsations would, to some extent, be transmitted through the medium near the tube, be it flesh or otherwise. This would explain how Prof. Thomson got an X-ray burn through a piece of metal placed over the flesh during the exposure. If the piece of metal had been large enough it would no doubt have taken the pulsating current of electricity and protected the part exposed to the X-rays.

2. The flesh did not become dead until about two months after the exposure; if the proper treatment had been pursued at once the affected tissues possibly would have rallied and become sound again.

3. The condition of the health of the persons subjected to the rays has something to do with the trouble. I had been using the same outfit and style of tube for various X-ray exposures, just previous to the time that the two troublesome cases were exposed. I took an X-ray picture of a bullet in a man's leg above the knee, exposed him longer than the cases mentioned and had no trouble.

ELECTRICALLY DRIVEN PLOUGHING TACKLE IN GERMANY.

FROM time to time during the last ten years and more, says "Engineering," we have heard rumors of steam and horses being supplanted in ploughing by electricity, but the affairs have usually been only experimental and have led to no permanent results. Lately, however, the system has been worked out in Germany on a commercial basis, and we are now able to lay before our readers illustrations of machines constructed by Mr. A. Borsig, of Berlin, and now being used in many localities. Electric ploughing tackle is best adapted

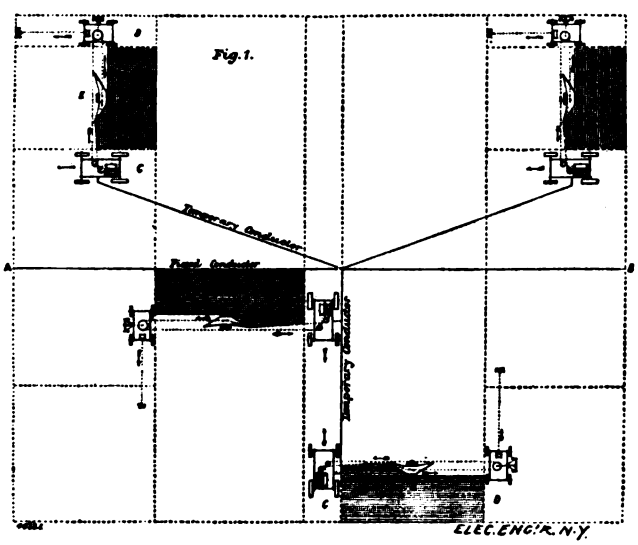

FIG. 1.—ELECTRIC PLOW CIRCUIT ARRANGEMENT.

to meet the requirements of the great beetroot estates in Germany, which are devoted to the manufacture of sugar, for they are of large extent, and have command of capital to enable them to adopt all labor-saving appliances. Further, there are, on such estates, large installations of steam power, which lie idle a great deal of the year, including that period at which ploughing is done. Hence, by the addition of dynamos, and of a system of overhead conductors in the fields, it is possible, at small cost, to adopt electric ploughing over a large area.

The overhead conductors do not extend into all the fields, but are tapped by temporary wires laid on the ground, as required. Fig. 1 shows eight fields, with four sets of tackle at work, all drawing current by temporary connection with the overhead wire A B. Each set of tackle comprises a "motor wagon" C, an "anchor wagon" D, and a plough E, which is drawn backwards and forwards between the other two, cutting five furrows, as shown by the parallel lines. On the motor wagons is fixed a 40 horse-power alternate current motor, with necessary switches and driving gear, both for the hauling and traveling, while the anchor wagon carries the anchor, and a sheave round which the hauling cable runs. It is possible with an electric conductor of 500 meters (1,640 ft.) and a ploughing rope of 300 meters (985 ft.) working length to plough 222 acres from one center of operations.

The motor wagon, Fig. 2, carries two drums on horizontal axes. On these the two ends of the rope are wound, the bight passing round the sheave on the anchor wagon. One drum is driven to draw in the rope, while the other runs under a brake, to keep the tail rope fairly taut. The two parts of the

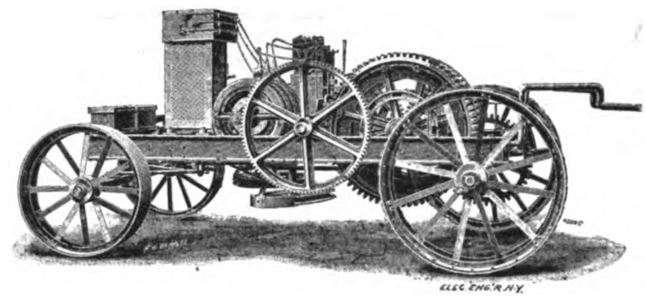

FIG. 2.—ELECTRIC PLOW MOTOR WAGON.

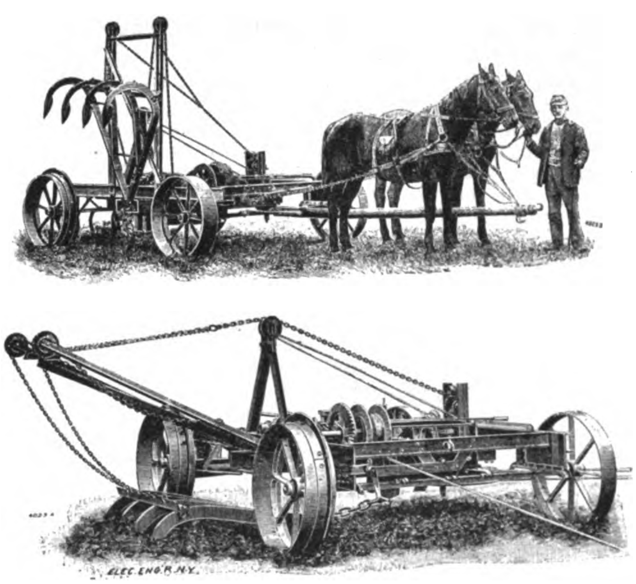
rope are led round guiding sheaves, revolving in horizontal planes, under the wagon. The two rear wheels can be connected to the motor by clutches and gearing to propel the wagon, while the two leading wheels serve to steer it. On the opposite side of the wagon to that shown in the view, there is a platform for the attendant, with the various handles and levers grouped in front of it. The weight of a motor wagon is 7 tons.

Mr. Borsig states that with fixed steam engines of 250 horse-power, and with five ploughs, 6,000 acres of medium heavy ground can be ploughed to a depth of 14 inches at a cost of 92 cents per acre. If separate engines have to be employed, the cost per acre is increased by 14 cents per acre.

The anchor wagon, Figs. 3 and 4, carries a sheave round which the ploughing rope runs. The sheave is fixed in a



FIGS. 3 AND 4.—ELECTRIC PLOW ANCHOR WAGON.

guide, and is connected by a chain to the anchor. Hence as the anchor sinks into the earth under the pull of the rope, the sheave and it move together. The anchor itself has four prongs, and is hung from a light crane, or derrick, by which it can be completely raised for traveling (Fig. 3), if the jib be wound up by the worm hoist at the opposite side of the frame At other times it is manipulated by the chains running round the pulleys at the head of the jib. The slack end of the ploughing rope, when the plough is moving towards the motor wagon, actuates gearing which winds the anchor out of the ground, and moves the anchor wagon forward into the right position for the next double set of furrows. At the same time the anchor and sheave are moved backwards relatively to the frame to allow for the slip of the anchor in the earth. The anchor is then dropped by the attendant and the next set of furrows cut. The strain of the rope goes direct from the pulley to the anchor, and not through the wagon frame.

VOL. XXIV. NEW YORK, JULY 8, 1897. No. 479.

GROUT ON MUNICIPAL PLANTS.

THE latest number of "Municipal Affairs," a quarterly issued by the New York Reform Club, contains an article by the Hon. E. M. Grout in favor of municipal gas ownership for New York; an article by Mr. A. R. Foote controverting the other; and a rejoinder by Mr. Grout. The three are extremely interesting reading, and although the arguments are addressed to the subject of gas, they would, of course, apply in general with equal force to the municipal ownership of electric lighting plants or street railways. In fact the discussion does cover electric lighting not only inferentially, but directly, and the merits of that part of the subject are also gone into in some detail.

The value of Mr. Grout's article may be gathered from the fact that he quotes Philadelphia as an example for New York at the very moment when a scathing report has been presented urging "that it is better to lease or sell the works while they are yet valuable than to wait until their main value is destroyed by competition, fostered and maintained by inadequate management." Philadelphia buys more than half of its gas supply from a local company at 37 cents per 1,000 cubic feet, and it makes a profit on this by selling it again. Its own municipal plant and staff make 10,000 feet per day per man, when the average should be 30,000.

But we can leave Mr. Grout's fantastic gas figures to gas experts and journals. Mr. Foote polishes off a good many of them in neat style; and as Mr. Grout very ingeniously proposed to revise his paper after it had been answered, Mr. Foote neatly provides for that policy of evasion by quoting Mr. Grout bodily in his own text. It is evident that Mr. Grout does not relish being pinned down in such fashion. Turning, however, to the electric light figures given in his "rejoinder," which he obviously thought was safe, we find that most of them are derived from the notorious falsifications of the soi-disant "Prof." Frank Parsons and are two years old. Still, to take them as they stand, we note, for one instance, that Boston, Mass., with $139 per lamp per year from a private company is compared with Braintree, Mass., municipal plant, $66 per year. Very beautiful and convincing! But what are the facts? The arc lamps in Boston are 2,000 candle-power, 10½ hours per night, 30½ nights per month. The arc lamps in Braintree are 1,200 candle-power, 7.7 hours per night, 27½ nights a month. In other words, the Boston lamps give nearly double the light nearly twice the time, and yet Mr. Grout has the audacity to hold this up as an example of superior municipal cheapness, when on the most casual investigation he would have seen that Braintree was paying too much for its lamps. Another example cited by Mr. Grout is Alexandria, Va., with lamps at $72 per year. The last report from that city is that there is a strong movement to sell the plant, as the electrical service alone is operating at a loss of $1,000 per year, while the citizens are intensely dissatisfied with the running of things and the inadequacy of the service. Such articles as Mr. Grout's make us sick, yet we have no doubt it will be peddled out as the latest truth and gospel about municipal ownership.

FAN MOTOR WORK.

THE summer has thus far been cool beyond the ordinary, but with the coming of the Fourth of July a hot spell begins as usual, and the one now here will last with little interruption until some time in September. This heated period is the season within which the fan motor has of late years made itself most useful and conspicuous, creating a new branch of industry and throwing upon the central stations a load that forms an appreciable part of the total, in hot weather, when lamps and power motors are least taxed.

It seems to be accepted in some quarters as a self evident fact that only in very hot summers can one expect a fan motor boom, and that the fan market is necessarily dull if the months of June, July and August happen to be at all cool. Our own impression is that a demand for fan motors may be created that will last the year around, so far as the manufacturer is concerned, while the unused opportunities for introduction, even in winter, are still numerous. We know some offices and rooms where the fan remains always in circuit ready to help ventilate or cool the place. It is not always convenient to throw doors and windows wide open, for example, after several people have been smoking in a room; but if a fan motor is handy, the air can be quickly changed and the room freshened up. The same idea applies to the sick room or the bedroom, or rooms in which food is served. Fan motors can add a great deal to the comfort of life, altogether aside from their function of stirring up a breeze in a down-town office in midsummer.

One branch of work upon which we still build high hopes, is the more general employment of fan motors in hotels. The average hotel bedroom is a stuffy place, and in summer it is often more restful to stay out of them than to try to win sleep within their walls. We believe that hotel proprietors can materially add to their income and to the popularity of their houses by putting a fan motor in every room occupied by a guest. At any rate, if one hotel tried it, we venture to assert that competing hotels simply could not escape doing the same. In large apartment houses, also, where the bedrooms are frequently small, inner rooms, the use of fans would be a great boon and would help to secure staying tenants.

When we consider the large areas of the world, outside this country, where intense heat has to be endured, it does seem likely that in due course a large export trade can be built up in fan motors. It is a branch of business this country has little or no competition in. England, Germany, or France, where the fan motors might be made, are almost wholly ignorant of their uses and advantages, and have not at all studied the many points connected with their manufacture. Regions like South America, the West Indies, South Africa, Egypt, India have a ready welcome for this neat little modern appliance of comfort, and are rapidly becoming better equipped with the requisite sources of current supply. One other field of general utility is that of ship board, where electric current abounds, and where a good breeze between decks is a perfect boon at any season of the year, and particularly in the tropics. Altogether, the market for fan motors has but barely opened up.

NATIONAL TELEPHONE TOLL TRUNK LINES.

ONE of the most important underlying questions discussed openly or quietly at the Detroit independent telephone convention, was that of toll lines. Many of the independent local companies are building, or have built such lines. Others have "pooled their issues" so as to enjoy in common a toll system connecting their various local systems; and as one speaker put it, great States like Wisconsin are already covered with the webs of independent toll lines. But it is when the competing system comes into rivalry with the superb network of the American Telegraph and Telephone Company's long distance lines, that the absence of anything to compare with it is deeply felt, and the weakness of the independent service without it becomes painfully apparent.

How shall this condition of affairs be dealt with? If the expectations of Mr. J. E. Keelyn, of Chicago, are realized, the time is rapidly approaching when telegraphing, telephoning and possibly the postal system of the United States, will be operated upon sound business principles, in which the government will have supervision and, to some extent, a co-operative interest, and in which the charges will be limited to a

figure insuring a fair profit on the investment, but also providing a perfect service. The plan may take any one of several different forms, but the most feasible and probable is one involving a trunk system of wires, extending East and West and North and South, built by the federal government and operated partly under its control, though not necessarily so. These trunk lines will furnish a means for the establishment, through existing telegraph and telephone lines, of a system of interstate communication, covering the entire continent. The plan has merit, but we doubt whether the government just now or at any time wants to add to its big burden of debt and worry by owning and operating telephone or telegraph trunk lines. It would be better to have the government hold its hands off, just as it would be better to have the post office operated by private management, and thereby become efficient. If there is profit in such trunk or toll lines, the capital will in due time come forward to build them, just as it has to create the new independent telephone exchanges all over the country.

NO TAXES IN GLASGOW.

IF there is anything that makes the plain, average Glasweglan tired, it is to be told that they pay no taxes in his city. This, however, is the charming legend that has been going the rounds of the American press for a long time, and now, we regret to note, the "Scientific American" gives credit to the same yarn in a column editorial, approving and recommendatory. The original form of the legend was that all the city expenses were paid out of the profit of the municipal street railway system. We pointed out recently that the city has a debt of $39,852,175, with 10,000 employés drawing $10,000,000 salaries per year, and that the nominal return of profit from the municipal street car system was about $45,000. Now this revised version crops up, and is attributed by our contemporary to a Mr. J. A. Johnson, in the "Morning Call," of San Francisco. We do not distinguish Mr. Johnson, but we venture to say that if he asserted that "the city of Glasgow, Scotland, is in the fortunate position of being able to pay all the expenses of the city government out of the revenue derived from its public improvements" he doesn't know what he is talking about or is intentionally misleading. What does the statement mean? What are the "expenses" referred to? Are the salaries of $10,000,000 per year included? If the city is making so much money, why is it fortunate because it wants to borrow large sums in addition to the thirty-nine million dollars it now owes?

We have some acquaintance with Glasgow, and should greatly hesitate to hold it up as an example to any modern American city, although it is deservedly proud of being the second city in the United Kingdom. Its vaunted street car service would not be tolerated in America, and it is in itself one of the reasons why the poor are so crowded that the city wants to tear down the slums in which they live. A system of fares prevails which operates against the poor man and prevents his living in the suburbs, while the system of our American street car lines is building up everywhere the finest suburbs of sturdy house owners the world has ever seen. And as for the absence of taxation in Glasgow, we respectfully request the "Scientific American" to interview any decent citizen from the dirty city by the Clyde and ask him what he thinks about it. Our contemporary will soon ascertain that Glasgow is not yet the socialistic heaven where everybody can get everything for nothing at nobody's expense.

ELECTRIC SAFE BURGLING.

THE recent scare engendered among banks and other money institutions by the announcement that safes could be readily perforated, with evil intent, by the aid of electricity derived from convenient lighting and railway conductors seems to have subsided somewhat; but that the subject is still occupying the attention of safe experts is evidenced by a letter which we publish on another page. Our correspondent's account, however, would have been more convincing if he had not withheld the data which he refers to, and which would have an important bearing on the point at issue. His experiments, like all others of the same kind, do not, to our mind, prove anything. The ability to weld a hole in a piece of metal by means of an arc is one thing, but actually to open a safe by that means without the use of explosives is another. So far as we are aware that has not yet been done. That the burglar is willing to give the method a trial, however, is shown by the report that at Chagrin Falls, O., recently, gentlemen of the craft tried to enter a safe by the aid of current, obtained from the railway circuits. We are told that they had "nearly succeeded in melting off the knob" when the current was shut off, as is the railway company's custom at midnight. It would be interesting to know further details of this pioneer experiment; among other things, how long it took to "nearly melt off the knob" with a 500-volt railway current. Indeed one might almost wish that the burglars had succeeded in order to set at rest a question that seems to give rise to so much unnecessary uneasiness. In the opinion of those best qualified to judge, the successful breaking of safes by electricity is highly problematical and until the fact is actually demonstrated we must continue to express our doubts as to its "commercial" feasibility.

AUTOMATIC TELEGRAPHY.

IN this week's issue Mr. P. B. Delany brings to a close his most interesting and valuable review of the state of the art of telegraphy as it exists at the present day, with reference to obtainable speed of transmission. While advocating a system in which he is personally interested, it will be admitted, we believe, that Mr. Delany has treated the methods in vogue at present in a fair and unbiassed manner, and if this be so, then it may well be asked whether improvement is not desirable. Mr. Delany has gone far enough into the practical working out of his ideas to set at rest all questions of that nature, and we understand that his automatic system will, in all probability, soon be given a practical, commercial trial. As to the broad criticism that the system is not adapted for general work, that is a point which will probably always be raised against any automatic system, no matter what its nature. The paying quality of any automatic system must depend upon the volume of traffic or the load factor, if we may borrow that term from another department of electrical work. Indeed the problem presents itself very much in the same manner as does that of the relative advantages of steam and electric traction on present steam roads. It is the great volume of business that now goes by the comparatively slow mail, which Mr. Delany desires to see transferred to the wires and not the short telegram which is still the last resort of the majority of business men. Mr. Delany's system bears all the imprints of a practical method, but whether he succeeds, or not, his governing idea of a telegraphic post is bound, sooner or later, to come to a head.

ELECTRICAL ENGINEER VOLUNTEERS.

SINCE the suggestion by Dr. John Hopkinson, a year ago, that the English electrical engineers form a volunteer corps as an adjunct to the regular Corps of Royal Engineers, considerable progress has been made, and it is now announced that an organization has been effected, and a code of regulations issued. The new volunteer corps has as its honorary colonel Lord Kelvin, with Dr. John Hopkinson as the commanding officer, while other well known and able English electrical engineers have signified their willingness to accept commissions. The objects of this newly organized corps are briefly stated on another page. Warlike operations on land and sea to-day involve electrical operations in so many forms that the eminent value of a trained auxiliary body of electrical experts must add immensely to the fighting strength of any country fortunate enough to possess one. Indeed, so well are we impressed with the importance of the matter that we would strongly urge the formation of a similar corps within the ranks of the American Institute of Electrical Engineers. President Crocker might well give this matter his serious consideration, and we predict a rousing reception for the U. S. Electrical Engineer Volunteer Corps with him at the head.

IN the early days of the X-ray it was suggested, in this journal, among other places, that the new phenomenon could be utilized at custom houses. The idea is now being tried practically by M. Pallain, French Director General of Customs, who has had apparatus fitted up in the customs room of several of the larger frontier railway stations. The results are so far said to be satisfactory, and if further results are equal to the present, the method may be generally adopted in France.

ELECTRIC TRANSPORTATION

THE WILLARD SECTIONAL THIRD-RAIL SYSTEM.

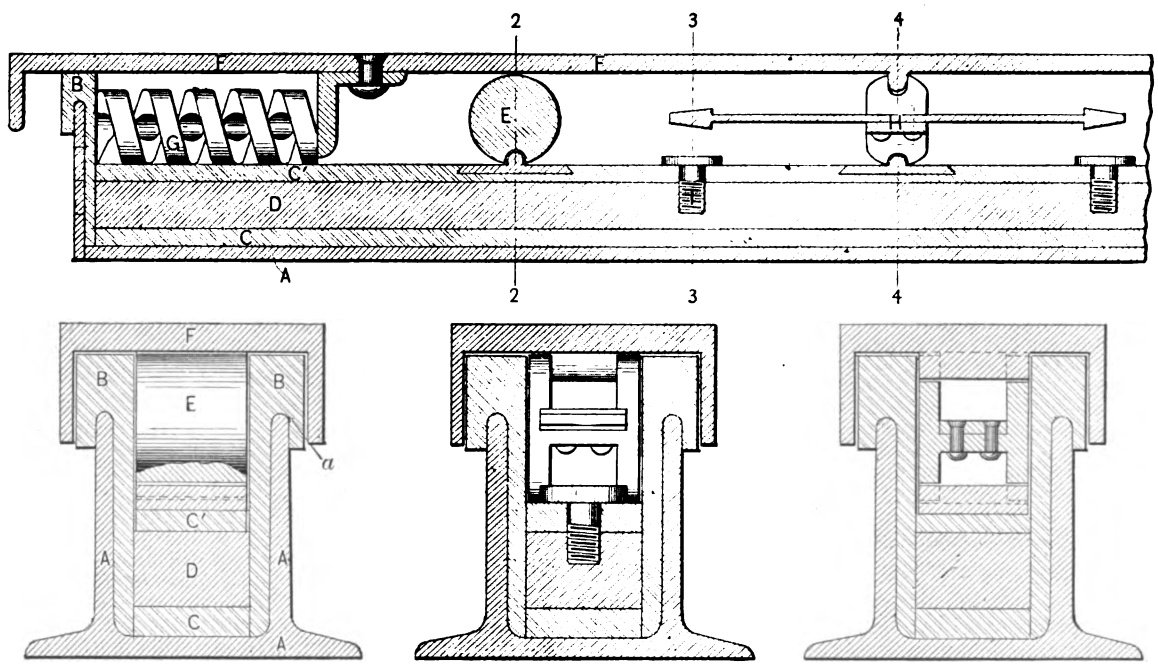
PERHAPS the only objection raised against the third-rail system of conductors as established on the New York, New Haven & Hartford R. R. is the fact that the third rail is "alive" and therefore liable to lead to accidents. With this drawback in mind, Mr. W. A. P. Willard, Jr., of Boston, formerly employed on the Nantasket Beach branch of the N. Y., N. H. & H. R. R., has designed a system in which each rail becomes energized automatically as the train passes over it, and becomes "dead" immediately after the contact shoe passes off the rail to the next, which is energized in turn.

The accompanying engravings illustrate Mr. Willard's system in detail. Fig. 1 is a longitudinal section of one-half of the rail. Fig. 2, a section through line 2 2; Fig. 3, a section through line 3 3, and Fig. 4, a section through line 4 4.

In Fig. 2, A is an iron trough rolled in suitable lengths; B B is an insulator made in lengths equal to the iron trough and held in place at the top by hooking over as shown at a. C. is also an insulator and also continuous. It also serves to hold B in place at the bottom of the trough. C' is also an insulator. D is the "live" conductor surrounded by the insulators, B C C', which in turn are protected from the weather by the iron trough A A. E is a supporting roller and is used to support the contact top, F. A loose spiral spring, G, is placed at each end of the rail. H is the contact rocker and is represented in a "dead" position. I is a flat-headed bolt connected with the live conductor, D. It will readily be seen that a short longitudinal motion given to the contact top, F, will compress the spring, G, and give to the rocker, H, a quick motion connecting the "live" conductor, D, through the bolt, I, and rocker, H, to the contact top, F, and as soon as the shoe has passed to the next rail the spring, G, quickly moves the contact rail, F, back to the "dead" position as shown.

The whole of this rail being made of iron and wood, it can be built very cheaply and as all the wearing parts, G, H and E, are very cheaply made and simply dropped in position, it requires no skilled labor to make repairs; hence, the maintenance of this system is estimated to cost very little.

The conductor, D, has an area of nearly eight square inches, and being made of heavy carbon iron will safely carry a large current. The amount of drop in potential in operation of this system will be about the same as in any well constructed insulated line.



FIGS. 1, 2, 3 AND 4.—WILLARD AUTOMATIC SECTIONAL THIRD RAIL SYSTEM.

NEW G. E. 52 RAILWAY MOTOR.

THE General Electric Company announces a new street railway motor, of less capacity than the now well known G. E. 1,000, but of greater capacity than the familiar G. E. 800.

The new G. E. 52 motor, Fig. 1, has an output of 28 horsepower rated according to the G. E. standard basis, i. e., a maximum rise of 75 dgs. C. in the temperature of the windings after a run of one hour at rated load, the temperature of the surrounding air not exceeding 25 dgs. C. The G. E. 52 motor is intended only for ordinary street railway work and is not recommended for the heavier service to which the G. E. 1,000 motor is adapted, and will accommodate electric brakes; but as some additional capacity is required for brake service, the company does not recommend this motor for such work except in purely street railway service.

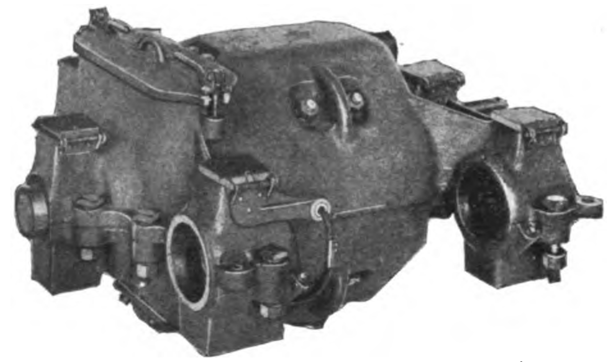


FIG. 1.—G. E. 52 RAILWAY MOTOR.

The frame is of steel, cast in two bowl-shaped pieces, and hinged and bolted in such manner that the motor is practically water and dust proof. A hand hole, fitted with cover plate and gasket, is let into the lower half, directly beneath the commutator, permitting easy access to the bottom of the motor for inspection or for the removal of any foreign substance. The motor has four poles, each with its own coil. The pole pieces,—and in this feature the motor differs from the G. E. 1,000—are laminated, but are bolted to the frame in the same manner as in the G. E. 1,000, the bolts extending through the frame.

The large bearing surface of this motor is one of its most important features. The armature bearings, designed for the use of oil or grease, or both, are of the following dimensions: Pinion end, 7¾ in. x 2¾ in.; commutator end, 6⅝ in. x 2½ in.; they are constructed on the "outboard" plan. The upper sup-

port for the lining is cast with the upper half of the motor frame, and when the lining is in place, there is a space of one inch in the cored recess, between the inner end of the lining and the motor frame. This space is occupied by a combination thrust collar and oil guard. The thrust collar is extended through the motor frame into the recess where it acts as an oil guard. This portion of the collar is a tapered disc, 6½ inches in diameter. The lower support for the lining is a cap bolted to the upper half, but not enclosing the lower half of the oil guard. This allows free outlet to the oil or grease. With this construction it is impossible for the lubricant to work into the motor.

The field coils are wound with asbestos covered wire and "mummified." Each is held in place on its respective pole by means of the pole piece projections, supplemented by a spring steel plate, and is placed in position before the pole piece is bolted to the frame.

The armature is of the well known iron-clad hollow core type, 11 inches in diameter with a spread of 9 inches with three ventilating ducts. There are twenty-nine slots in its periphery, each slot containing three coils formed into a compact unit, consequently there are twenty-nine sets of coils and eighty-seven commutator bars. The small number of coils is

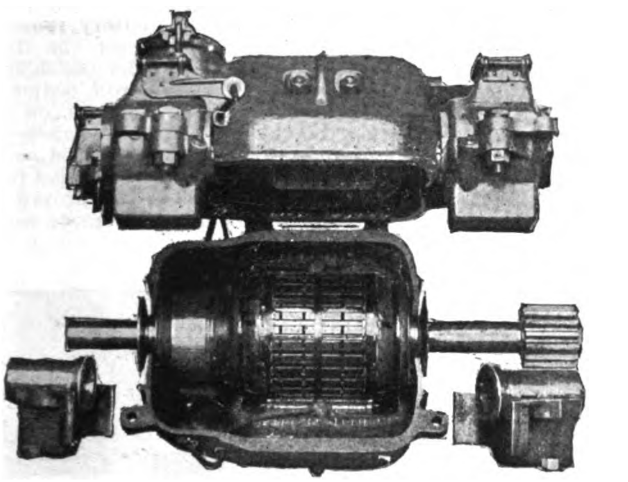

FIG. 2.—G. E. 52 RAILWAY MOTOR.

of special advantage in the matter of armature repairs, while the method of forming them in groups of three admits of a substantial insulation of high quality.

The standard gear ratio is 4.78 with taper bore pinion having 14 teeth and a cast steel gear having 67 teeth. Higher speed gear ratios may be used, furnishing increased speed with proportionately decreased tractive effort.

The brush-holders are standard and staggered to prevent the wearing of ridges in the center of the commutator. Each holder contains two radial brushes, 2¼ inches long, 1¼ inches wide and ½ inch thick.

The suspension can be either the nose, the yoke, or the sidebar, as with the G. E. 1,000 motor. The yoke suspension is especially recommended, as with this suspension the weight of the motor is carried on springs, placed upon the side frames of the car trucks. Lugs are cast on the upper half of the motor frame, to which the suspension bar is bolted, the motor being suspended from the top half. This permits easy access for inspection or repairs, as the lower half can be swung down into the pit, as shown in Fig. 2.

When the motor is mounted on 33-inch wheels, the clearance between the bottom of the motor and the top of the track rails is 5⅞ inches. The clearance between the bottom of the gear case and the top of the track rail is 4⅝ inches, a feature which railway men will appreciate. The motor without gear or gear case, weighs 1,450 lbs.; complete, and with 67 tooth gear and malleable iron gear case, the weight is 1,725 lbs.

LOS ANGELES, CAL.—The Main street and Agricultural Park street railway lines have been relaying their track with standard 6-inch, 60-pound rails, with the object of substituting electricity for horse power. It is the last animal power line in the city.

MR. C. P. HUNTINGTON states that his Southern Pacific Railroad is seriously contemplating the use of electricity on its broad gauge lines at Oakland, Cal., with some 40 miles of track, carrying 17,000,000 people for the ferries.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—XVI.

BY JOSEPH APPLETON.

(COPYRIGHT, 1897.)

STORAGE BATTERIES IN EDISON STATIONS—(Continued).

THE Philadelphia Edison Electric Light Co. installed last year a storage battery plant which has a greater capacity than any other individual battery in the world. There is one at Hartford, Conn., in which the cells are larger, but

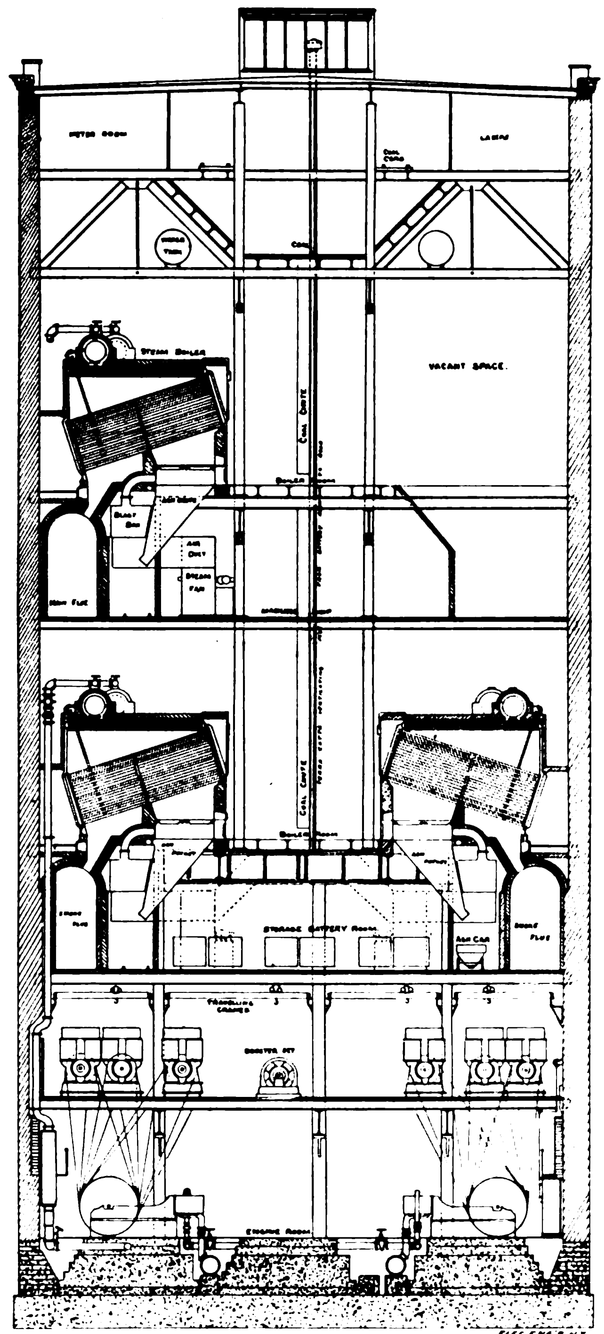

FIG. 62.—STORAGE BATTERIES IN PHILADELPHIA EDISON STATION.

the total output of the battery is not so great as fewer cells are used; this plant will be described later.

The storage battery at the Philadelphia Edison Station consists of 160 cells. Each cell contains 57 plates 31" x 15½", the dimensions of the lead lined tanks being 46" x 18" x 39¼" deep inside. The capacity of this battery is 1,520 amperes for ten hours; 3,750 amperes for three hours; 4,500 amperes for two hours; or 7,500 amperes for one hour.

This plant is especially interesting and worthy of notice on account of the care with which all the details have been studied and worked out, it being, undoubtedly, the most complete central station battery plant ever installed.

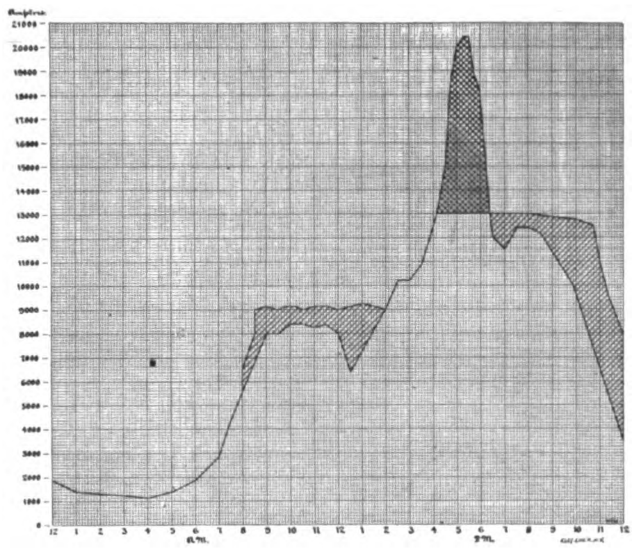

Fig. 61.

The Philadelphia Edison Co. have one large station from which all the current is distributed. The generating plant consists of 26 Edison bi-polar dynamos belted to Armington & Sims engines, having a total capacity of 26,000 amperes. Fig. 61 shows the load curve for a winter's day. In 1896, it became necessary to provide additional capacity in the station, and after most careful consideration the Edison Company decided to install a storage battery, instead of more generating machinery, believing that by so doing they would get a better return on the investment. The results have fully justified this belief.

The general arrangement of the battery plant is as follows: The battery is located on the third floor which was formerly used as a machine shop and store room. Fig. 62 shows a section of the entire station and gives a good idea of its general arrangement of same. Fig. 63 shows the interior of the battery room, and Fig. 64 illustrates the arrangement of the cells, also the run of copper conductors between the end cells and the regulating switches. These switches are located on the main stairway of the building, on the outside of the battery room wall; they are mounted on channel irons built into the wall, and so arranged that the connecting studs project through into the battery room where they are connected to the copper conductors. The battery switchboard, from which all the operating is done, is located on the main switch gallery of the station, in the dynamo room, on the second floor immediately underneath the battery room. Fig. 65 illustrates the method of connecting the storage battery equipment to the general system.

We will now consider the various portions of this plant in detail, commencing with the battery and battery room.

The battery being located immediately over the dynamo room, special precautions were taken to render the floor thoroughly water-proof. After the additional iron beams were laid, they were covered with a layer of concrete, on top of which was placed three thicknesses of tarred paper coated with pitch to render it water-proof; on this was laid chemical brick set in cement for about one-half the depth, the remaining half being filled with hot pitch. This has proved to be a most satisfactory construction, being inexpensive and fills the conditions in every way.

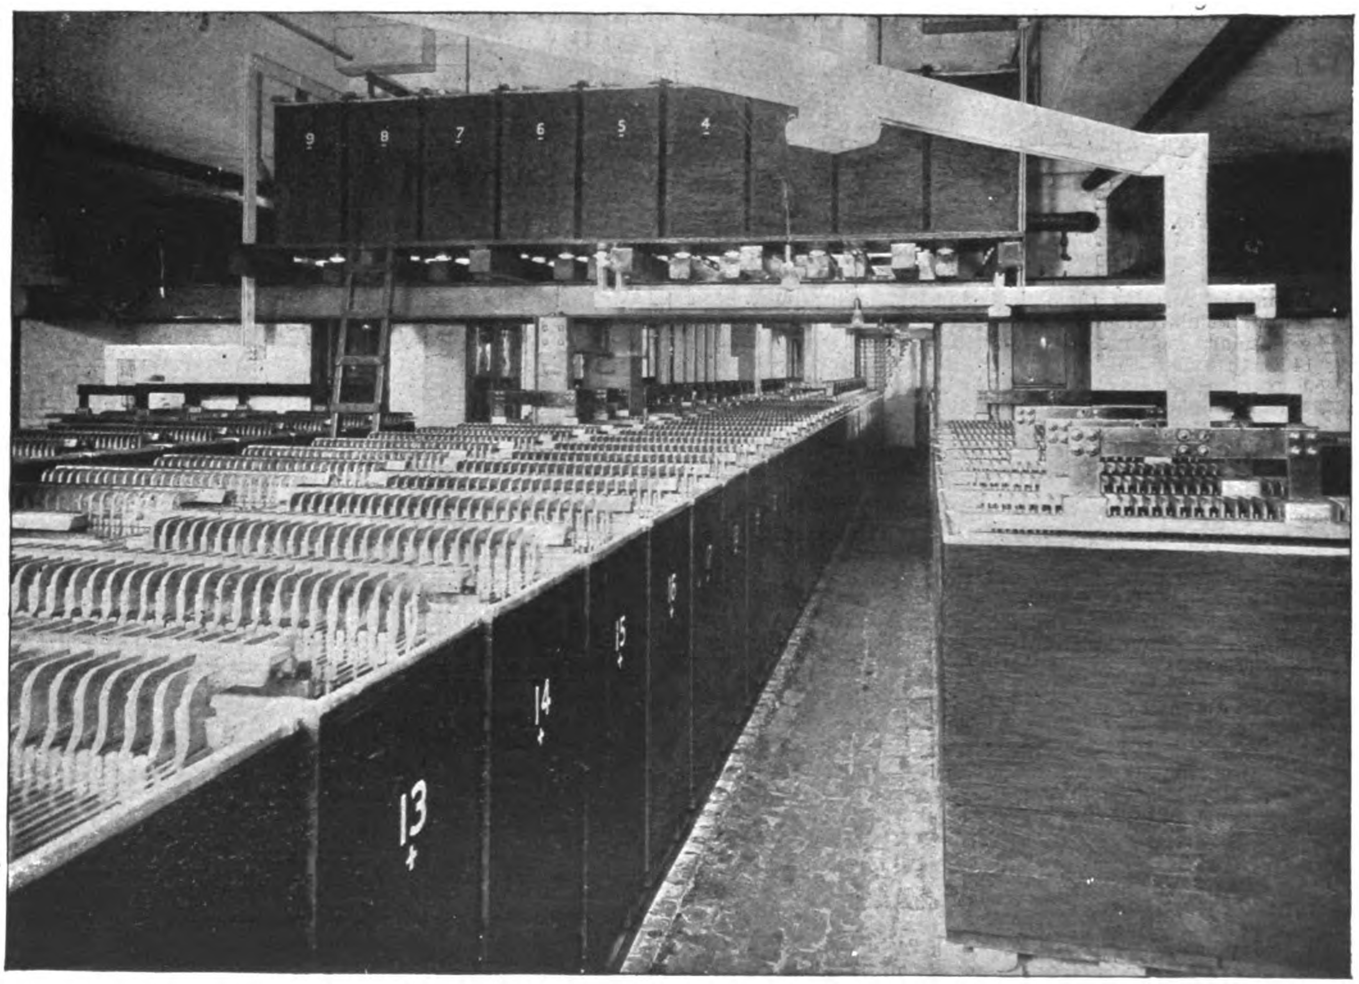

Fig. 63.—Battery Room, Philadelphia Edison Station.

The aisles are graded so that any liquid will drain off through the drains provided. The cells are supported on eight special double petticoated porcelain insulators, which are set on vitrified tiles to raise them slightly off the floor.

This arrangement gives good insulation between cells, also between the battery and ground. The battery tanks are constructed of well seasoned ash, 1¾ inches thick, dovetailed together and lined with 4 pound lead.

The plates in the cells are supported on sheets of glass as and one which secures the equal working of all the plates in the cell.

Thirty of the end cells on each of the three-wire system are connected to the cell regulating switches, so that any number from 51 to 80 may be used on the system. The connections

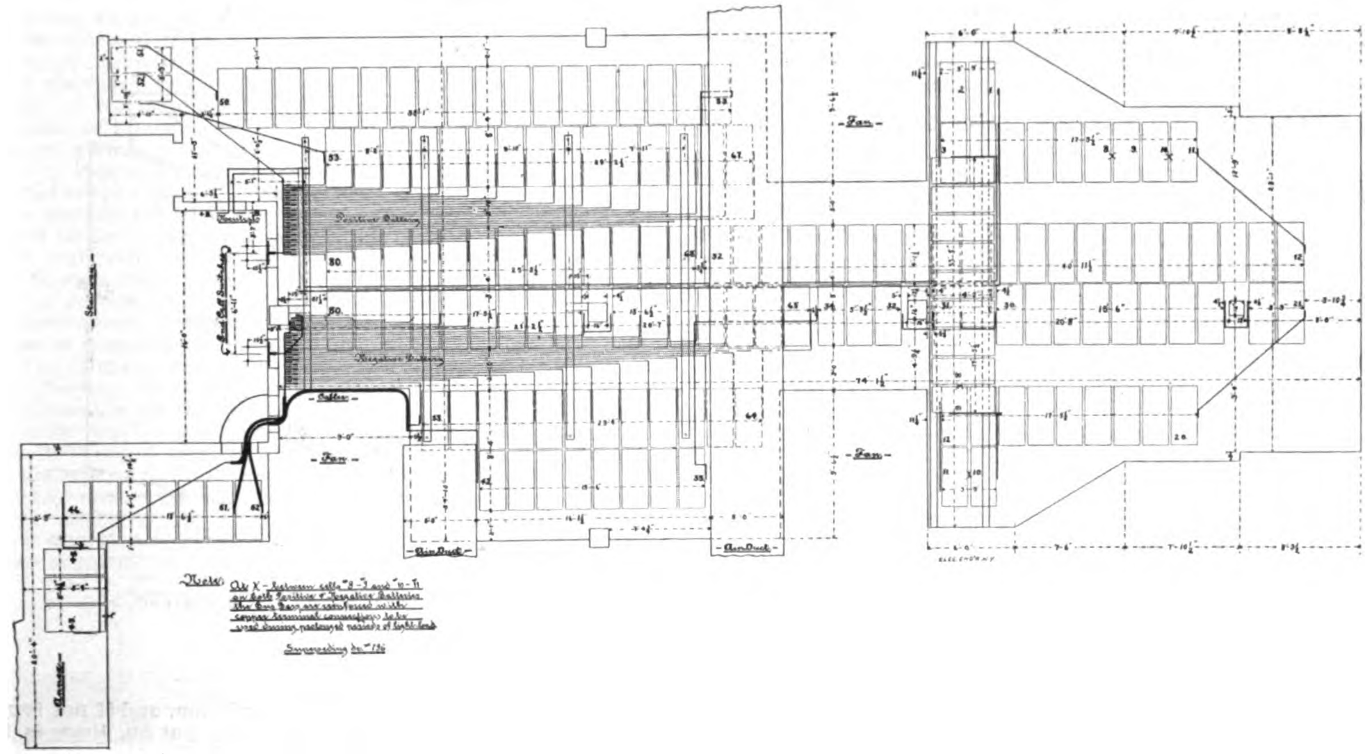

FIG. 64 —CELL CONNECTIONS IN BATTERY ROOM, PHILADELPHIA EDISON CO.

shown in Fig 2. All the plates are burned to rolled lead bus bars which also form the connection between adjacent cells, connecting them in series. All cells from which external connections are taken, either for the cell regulating switches, or to join one group of cells with another, have the lead bus bars re-enforced with a strip of copper placed underneath between these cells and the cell regulating switches are made with rolled copper bars supported on porcelain insulators mounted on channel irons hung from the ceiling. These copper bars have a sectional area of two square inches; the horizontal runs are made with bars 4"x½", while the vertical lengths consist of two pieces 4"x¼", placed on each side of the

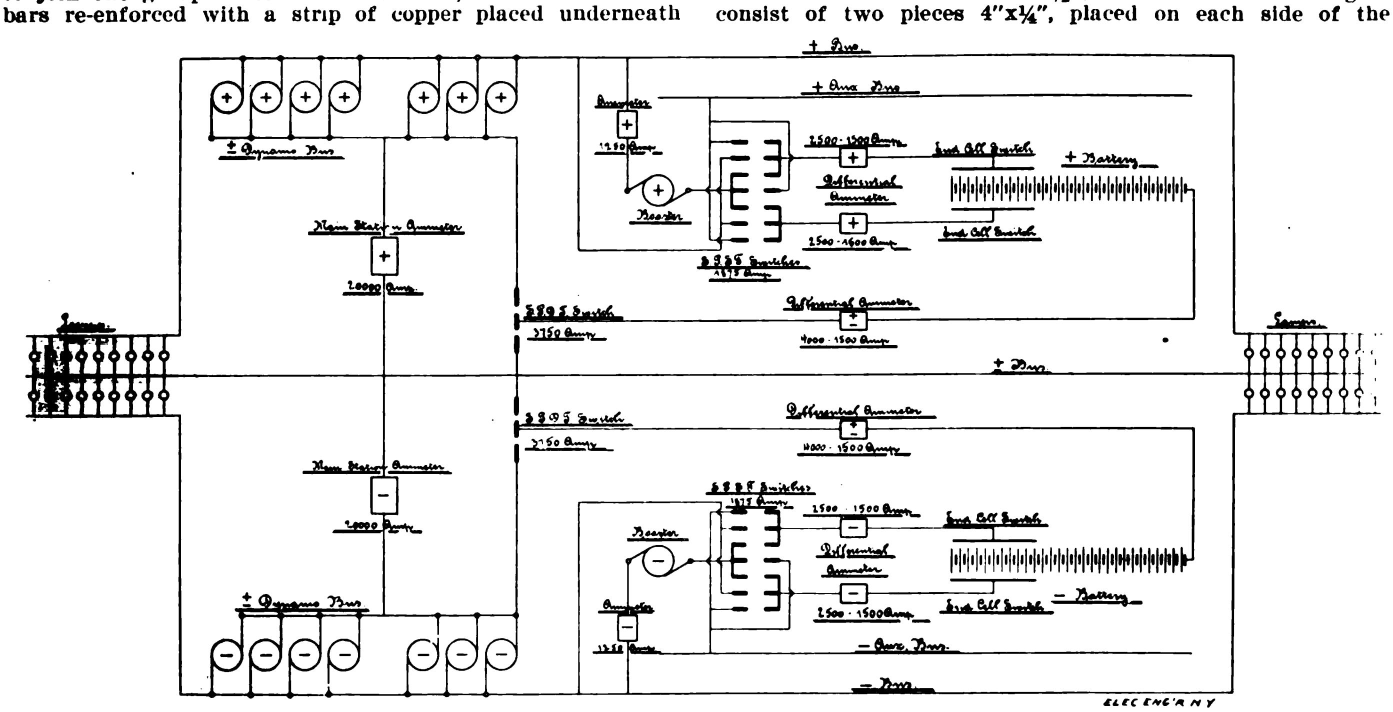

FIG. 65.—CIRCUITS OF STORAGE BATTERIES IN CONNECTION WITH THREE-WIRE SYSTEM, PHILADELPHIA EDISON STATION.

same, and thoroughly sweated in with solder, then coated with lead for protection from corrosion.

On the top of these bus bars lead cups are provided into which the copper conductors are sweated; these conductors extend through the lead bus bars to the re-enforcing copper strips to which they are brazed, thus giving an excellent connection horizontals so as to give double the contact surface at the joints.

All the joints are bolted together with four ⅝-inch bolts, the surfaces of the copper bars being treated with the Edison Brown plastic alloy; the joints made in this way have given excellent results, showing a lower temperature than the cop-

per bar itself when the maximum current is flowing. All the copper conductors are painted with an enamel paint to protect them from the acid spray and gas which is given off while charging the battery.

The battery room being in the middle of the building, means for ventilation had to be provided. This was done by running two 12 inch terra cotta flues right to the top of the building which, with the windows at the end of the room, provide ample ventilation without the use of fans or blowers.

ELECTRICAL MACHINE SHOP PRACTICE.—II.

BY JAMES F. HOBART, M. E.

COMMUTATOR segments are now made in several ways, the two best of which seem to be by drop-forging from the solid bar, and by casting and then drop-forging to a finish of the exact size required. Some shops prefer the latter method for extra nice work. Segments thus made, cost a trifle more, I believe, than those made entirely under the drop hammer.

Setting up commutators, while usually done in the ring with a double row of setscrews, can sometimes be well exe-

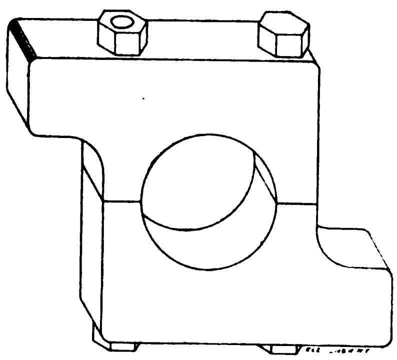

FIG. 4.

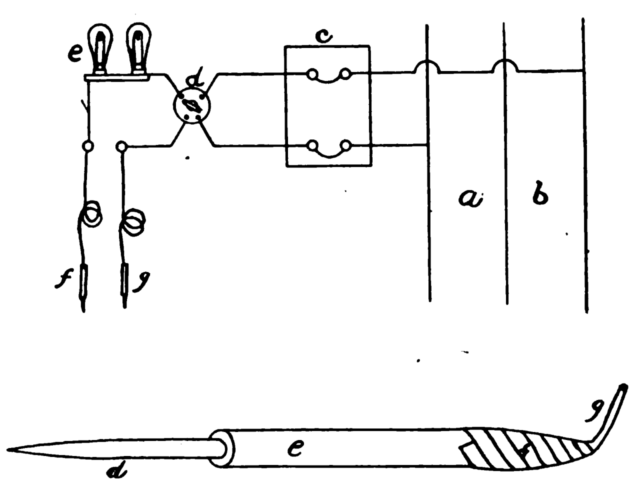
cuted with the clamp shown in Fig. 4. This is a solid cast iron affair, made, as shown, to be pulled up tight around the commutator, by means of the two turned bolts that fit pretty snug in reamed holes. At least, the holes are reamed at the points where the two parts of the clamp come together, in order that there may be no offsetting of the clamp as it is screwed together. A couple of stout dowell-pins can be put in, if found necessary, to relieve the bolts of the lateral strain.

The commutator being set up, and clamped up while hot, is baked to consolidate the insulating material, through a heating of the shellac, or other substance used for cementing the



FIGS. 5 AND 6.

mica, or other insulating substances. After this clamp has been screwed home, and the commutator baked while screwed up in it, there is little question to expect otherwise than the commutator will come out perfectly round, and otherwise in excellent condition. Another good thing about this clamp is it can be used for a lathe dog, as well as a clamp while turning up the ends of the commutator, for the reception of the conical collars which hold it to the armature shaft.

Being made symmetrical, the clamp is perfectly balanced, and can be run at high speed for brass turning and finishing. The projecting arms serve as "tails" to the dog, while driving the work in the lathe. The commutators had better be tested while in the clamp, as it is frequently the case that small cop-

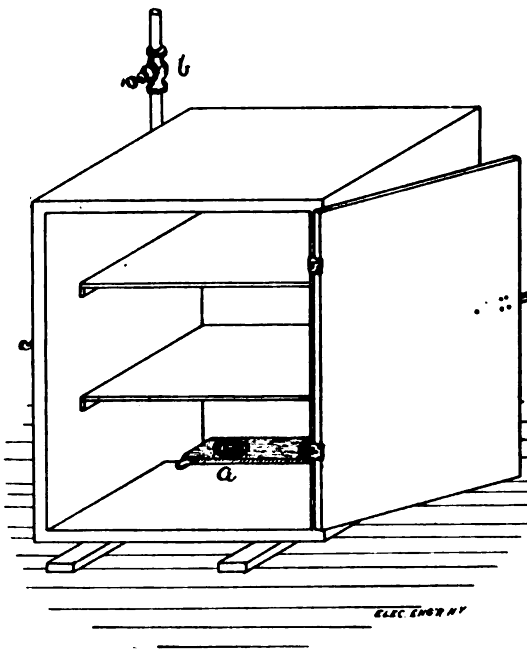


FIG. 7.

per chips get driven into the mica insulation, and if not found and removed before the cone collars are put on, there is the necessity of taking the commutator all down again to get them out, and that is an expense to be avoided.

Testing can be easily provided for while the commutator is in the clamp, by wrapping some mica, or other insulating material around the commutator before screwing it up. As this is done, test the insulation by grounding one side of the test box on the clamp, and then stepping entirely around the commutator, with the other side, touching it to each segment in succession. No short circuit being found, as above searched for, and the turning being finished, test all round the commutator, holding one contact on a segment the other contact on

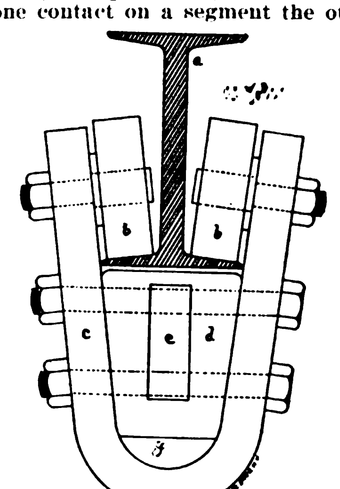

FIG. 8.

the next, then bringing the back contact ahead, and thus stepping clear around the commutator. Whenever a contact is found, search for it, and pick out the bit of copper with a sharp penknife or an awl.

Very little testing, during process of manufacture, is now done with Wheatstone bridge, or resistance box. And the magneto is not as much in evidence now as it formerly was. The tendency seems to be toward a 220-volt current or more for testing, and the use of incandescent lamps as a signal that there is a short circuit. A handy rig for the purpose is shown by Fig. 5, where a and b represent the leads of a three-wire system, giving 220 volts pressure as connected. A fuse box or

cut-out is placed at c, and in the shop where this device was noted, the workman disconnected one of the fuses before leaving the building at night. Regarding this precaution, he stated that it was a good deal easier to disconnect a fuse once or twice a day, than it was to build a new shop once.

His theory was that somebody might possibly go away and leave the switch, d, closed. Then, in case of accidental falling of the contacts, f and g, near any combustible matter during the night, there was possible the condition for a first-class fire. And the point was well taken.

One of the contacts is shown more in detail by Fig. 6. It consists of a steel wire, pointed as shown at d, and hardened like an awl, to stand a good deal of wear. A piece of rubber tube is slipped over the steel wire. The tube, e, is made fast by the rubber tape, f, to the wire, g, which connects the point with the source of current. The steel wire ought to be soldered to the copper lead, g, before it is taped.

Several "refinements" suggest themselves in connection with the danger from leaving current in this testing device. One of the schemes is to put a couple of contacts in each of the rubber-covered testing points, these contacts to be arranged in such a manner that they must be compressed or pinched by the thumb and fingers of both hands while in use, no current flowing when the contacts are not thus pressed, making it impossible for the testing points to do any harm when they come in contact when not in use, as no current can flow unless two sets of independent contacts are pressed all the time.

This will make things safe enough, but an element of unreliability enters the instrument when this is done, as the contacts might not be fully closed, and the lamps would not glow under such circumstances, even when two of the commutator segments were bridged over with a heavy piece of copper.

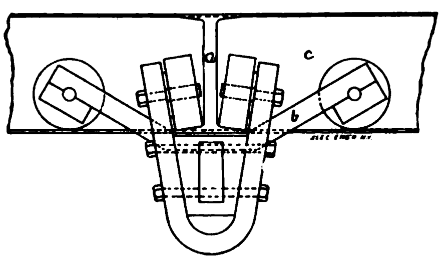

Fig. 9.

Otherwise, the safeguard would be an admirable one, and it is further suggested that a couple of colored lamps be so connected that they shall be lit at all times when current is available in the testing points and the contacts closed. Then a man would not test unless the red lamp was lit.

By another arrangement, the red lamps could be cut into the circuit shown in Fig. 5, and so arranged that they would glow when the switch, d, was closed, but would go out when the lamps, e, lit up, owing to the contact points being short-circuited. This would seem to make a pretty safe rig, as the fuse could be detached as at present, if desirable, and the red light would always be a reminder that the switch was closed.

Baking commutators is an important part of their construction. Steam heat hardly runs high enough to bake small commutators quickly enough, although it is used considerably for baking armatures. Steam will heat up to about 200 or 210 degs. F., and it gives a steady, even heat, but the gas-heated oven is given preference by those who have tried both steam and gas, and gas is convenient, and not very expensive, and also has the advantage of driving off moisture better than steam, for the reason that in a gas-heated oven there must be means for constantly introducing fresh air, and as the loaded heated air is driven off, it carries the moisture with it, while, when steam heat is used, the same supply of air remains dead in the oven, and the moisture stays there too.

Fig. 7 shows a very good form of gas oven. It may be made in any one of several ways, either by putting up a double sheet iron box, and filling between with asbestos, or by putting up a wooden box and covering the whole thing with stout tin. In the oven shown, it will be noticed that the whole thing is set up on pieces of wood, so there can be a circulation of air underneath. The air comes up through the bottom of the oven, the back part thereof being left open, as shown.

A gas stove, a, is placed in the oven, one of two, three, four, or even six, burners being used, according to the size of oven. The heat is controlled and graded by the globe valve, b, which regulates the gas supply to suit the work to be done. Shelves made of iron are put in, common cook stove grates being used in one oven of this kind. The oven represented in the engraving had a three-burner stove in it, and the oven itself was about 3 feet square and 3½ feet high.

A good many defects that come to light in armatures can be charged direct to bad handling during process of construction. It takes but a very slight knock to damage the insulation of a wire, or to drive a snag through some part of the winding in such a manner as to cause future trouble. One of the commonest causes of damage is during the putting of armatures into, and taking them out of, the lathe. No matter how small an armature may be, it should not be lifted into a lathe by hand, unless, indeed, it is so small that it can be easily held in one hand, while the lathe is adjusted with the other.

Use some form of overhead traveler, or a crane, if nothing better can be had. But a simple form of traveler, as shown in Fig. 8, consists of an I-beam, a, trolley wheels, b, b, which are set at an angle just right to make them run easily on the bottom web of the I-beam. A plain wrought iron strap, c, is bent up to the right angle to receive the trolley wheel axles, and the strap is held by bolts to a casting, d, which is mortised to receive the bar, e, which may be attached to a similar pair of trolley wheels if the work is heavy enough to warrant, but on light work, one set of wheels is sufficient, the hook for the chain hoist being attached at f.

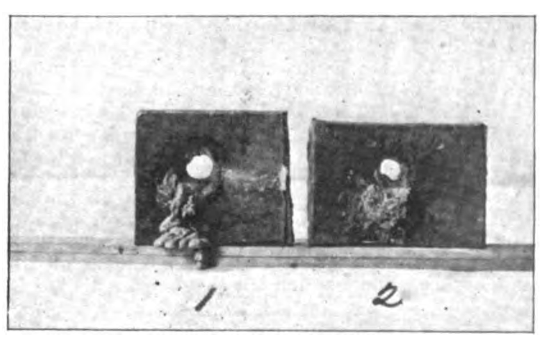
For some work it is desirable that the traveler have a movement lengthwise with, as well as crosswise of, the lathe, so that work can be moved right up to the centers, as well as merely swung into the lathe. For this purpose, a form of the traveler may used as shown in Fig. 9. This is the same kind of a trolley as was shown by Fig. 8; in fact, the same one may be used, another set of trolley wheels being fitted on at b, to run on the longitudinal I-beams, c, the hanger, b, being bolted to the I-beam, a, in such a manner that it runs on the lower flange of beam, c, exactly as the other wheels run upon beam, a. In this fashion a very stiff compound overhead traveler, of limited movement and capacity, is obtained very cheaply. Not only is it a simple form of construction, but it is likewise very stiff. A 4 or 5-inch I-beam will answer for almost any load that is likely to be put into a 15-inch lathe.

These travelers, or "lathe lifts," as they ought to be called, if taken in connection with trucks, or wheeled horses specially fitted to receive armatures, will effectually prevent damage while handling in the shop.

LETTERS TO THE EDITOR

SAFE BURGLING BY ELECTRICITY.

I HAVE been interested in the discussion which has been going on for the past few months about the possibility of using the electric arc in an illicit manner upon safe doors,



Perforations in Iron and Steel by the Electric Arc.

and the different opinions expressed pro and con by men held to be informed on electrical problems, led me to make a little private investigation myself and it did not take me long—only a part of one afternoon, to satisfy myself that it is as "easy as rolling off a log."

The enclosed photographs show two pieces of metal which I burned holes in at my first attempt; the one at the left is cast iron, the one at the right is the finest tool steel. Each piece was one inch thick. The hole in the cast iron was burned in less than one-half the time it took to burn the hardened tool steel and the time was so short I dare not tell it; nor do I propose to tell you, and, at the same time, the bank burglar, how it was done.

I will simply say that I used the wires I found in a mer-

cantile building using the Edison incandescent lighting circuit and that I carried everything I used in with me in a soap box. I stayed in a room about 15 feet square over two hours, using the current most of the time on different metals, and one window was up about 6 inches at the bottom; so much for the fumes, about which so much has been written. My "resistance" weighed less than 60 pounds; the current was said to be 110 volts, but what it may be I do not know or care. I used it for my purpose. No fuses were burned out and no one knew I was using the current for any such purpose.

I held the Edison carbon in my bare hand, simply wrapping my handkerchief around it. The metal melted at once and large globules ½ to ¾ inch in diameter ran out of the holes and cooling, touched and short-circuited on the carbon; but I made no attempt to clear them away; had I done so the time would have been shortened very materially. I would much rather burn a hole clear through 5 inches of steel with this current than try to burn 5 inches of oak with a red hot poker.

I consider the controversy settled and the only question that remains is, How are we to prevent it?

JAMES H. HOWARD.

Boston, Mass.

OBITUARY

HENRY B. STONE.

Henry B. Stone, ex-Vice-President of the Chicago, Burlington and Quincy Railroad, and ex-President of the Chicago Telephone Company, was killed at Nonquitt, Mass., July 5 by an explosion. Mr. Stone, with his family and other summer residents of Nonquitt, was celebrating the National holiday with a display of day fireworks. Among them was a bomb, which, when exploded, let loose paper animals of various colors. Mr. Stone had applied the torch to this piece, but it did not appear as if the spark was going to reach the mine. Mr. Stone advanced and took the piece up in his hands. It exploded, striking him full in the face. He dropped to the ground instantly killed. His features were badly mutilated, and he sustained a compound fracture of the skull.

He leaves a widow and four children. His remains will be sent to Chicago for interment.

PROF. DE VOLSON WOOD.

De Volson Wood, professor of mechanical engineering at Stevens Institute of Technology, Hoboken, N. J., died suddenly June 27. He was born near Smyrna, N. Y., in 1832, graduated from the Albany Normal School in 1853, and two years later from the Rensselaer Polytechnic Institute, Troy, and was appointed professor of civil engineering at the University of Michigan, which place he held for fifteen years. He then took the chair of mathematics of Stevens Institute, and later the chair of mechanical engineering, which he held at the time of his death. Prof. Wood was a member of the American Society of Civil Engineers, American Society of Mechanical Engineers and the American Association for the Advancement of Science, of which he was at one time vice-president. He was the first president of the Society for the Promotion of Engineering Education. He was the author of many text-books, which are in use at the principal technical colleges of the country and are authorities on higher mathematics and mechanical engineering. He was greatly liked by his pupils, many of whom are now filling places of distinction in the mechanical and electrical engineering fields.

LEGAL NOTES

STREET CAR MOTOR LITIGATION-GENERAL ELECTRIC CO. vs. WALKER CO.

Judge Putnam in the United States Circuit Court, Boston, on June 29 heard the bill in equity brought by the Thomson-Houston Electric Company vs. the Athol & Orange Street Railway Company. The plaintiff, as the owner of patent No. 448,260, granted to E. W. Rice, March 17, 1891, for an improvement in motor suspension, and of patent No. 470,817, granted to F. O. Blackwell, for an improvement in electric motors, brought this suit for an injunction to restrain the defendant from an alleged infringement of those patents. Both patents relate to different parts of an electric motor. The defendant uses the Walker motor, and it denies that it infringes upon the plaintiff's patents or that the patents are good.

F. P. Fish, J. J. Storrow and A. D. Salinger for plaintiff; C. E. Mitchell and H. B. Brownell for defendant.

TELEPHONE LITIGATION.

It is stated that Western Telephone Construction Company, of Chicago, have brought suit against the American Bell Telephone Company et al. for the alleged infringement of patent No. 581,350, taken out by Mr. J. E. Kellyn on a telephone receiver, now owned by the company first named.

INSOLVENCY SUIT AGAINST THE BEST TELEPHONE MFG. CO.

The John A. Roebling's Sons Company has filed a bill in Circuit Court No. 2, Baltimore, against the Best Telephone Manufacturing Company, of Baltimore city, in which it is asked that a receiver be appointed to take charge of the property and assets of the company, who would administer the property under direction of the court. Judge Wright signed an order that a receiver be appointed for the company unless cause to the contrary be shown before July 10, 1897.

It is alleged in the bill that the Roebling Company, in December, 1896, furnished the Best Company with goods to the value of $2,988.82, for which the latter has not paid. A suit for the amount is now pending in the Superior Court. The Best Company on June 23 denied the indebtedness under oath in answer to the case in the Superior Court. It is charged that it is false and is made to hinder the company from getting judgment. It is also charged the Best Company is insolvent and that it is necessary to have a receiver appointed to take charge of its assets.

SOCIETY & CLUB NOTES

THE ENGLISH ELECTRICAL ENGINEER VOLUNTEERS.

The corps of Royal Engineers (Volunteers) Electrical Engineers was suggested by a committee of the Institution of Electrical Engineers more than a year ago. The proposal was accepted by the War Office in a liberal spirit, and it is proposed to give important duties to the corps in connection with the defence of the defended harbors, and to treat it in regard to capitations and the like in exactly the same way as the Submarine Miners are at present treated.

The members of the corps will be placed under somewhat different conditions with regard to the requirements of the service from those of the rifle volunteers; for example, in the event of war they would be liable to be called out even though there was no fear of actual invasion.

The corps is intended to bring together a body of men having adequate knowledge of applied electrical science, and train them in the application of their knowledge to defence. The principal duty at present to be entrusted to the corps will be to undertake in connection with the home defence, to provide officers and men to assist the regulars in working defence electric lights at all defended ports, and, in particular, at certain ports of the first importance, where there is at present a deficiency of trained men. For this purpose, a certain number of electricians will be required, and a certain number of men accustomed to drive engines. In addition to this, it may be expected that the corps will have other duties in which electrical knowledge will be useful.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

We understand that the council of the institute at a recent meeting confirmed the action taken at the annual meeting in regard to the adoption of the new badge, and has decided that the number engraved on the back with the owner's name shall correspond with that on the institute roll; that is, be numbered consecutively in the order of their admission to the Institute.

Preparations are now being made for the general meeting at Greenacre, Me., and there is promise of a large attendance. A good list of papers and discussions has been secured.

CHICAGO ELECTRICAL ASSOCIATION.

On Friday evening, June 25, the members of the Chicago Electrical Association, accompanied by lady friends, accepted the hospitality of Mr. W. A. Harding, of the Calumet Electric Railway Company, in the form of an illuminated and spectacular trolley ride over the lines of that company. The evening was particularly fine, the preparations for transportation, illumination and entertainment were entirely complete, and the temper of the gathering was as full of vivacity as is usual with technical aggregations. At the close of the trip, after four hours' condensed enjoyment, vociferous cheers were tendered Mr. Harding and the Calumet Electric Railway Company, with a final for the association itself.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

Dynamos and Motors:

AUTOMATIC STARTING AND STOPPING ARRANGEMENT FOR ELECTRICALLY DRIVEN PUMPS.—By Alfred Oppenheim. A short article with one very clear diagram, descriptive of such an arrangement. The action of the device is mainly dependent upon a float contained in the reservoir; the float rising and falling with the changing water level. The arrangement described is, however, particularly valuable because it (a) allows the motor to be started slowly and without a jerk, and (b) because it is almost independent of the size and voltage of the motor.—Zeit. f. Electrot., April 15, '97.

Electro-Physics:

ON A NEW KIND OF BLACK RAYS.—By E. Friedrich in Elbing. An article on those rays lying farthest beyond the violet end of the spectrum and which he terms black rays, because they require bodies of the most delicate susceptibility to light, to make them visible. Author states that the invisible rays are more intense the farther they lie beyond the light giving rays of the ether, i. e., beyond the ultra violet end of the spectrum. Author terms refraction the "Energy" of light, and then states that the vibration of light is inversely proportional to its refraction and since violet of the prismatic colors has the least number of visible vibrations it hence possesses of the seven "rainbow" colors the greatest energy or refractive power. Author proceeds to develop a new etiology of rays in conjunction with a new theory of the ether and of colors; based on the facts that only a yellow-green fluorescing glass wall can furnish black rays while a blue or violet fluorescing glass wall cannot do so and because fluorescence itself is really superfluous since also non-fluorescing bodies such as platinum-tin, for instance, furnish black ether rays which are more intense than those furnished from fluorescing glass walls.—Ztsch. f. Elektrot., April 15, '97.

THE EMISSION OF LIGHT.—An editorial comment on a paper by H. Kruss, published in the "Journal für Gasbeleuchtung," 1896, Vol. 39, p. 425. The results given are those of the researches of Lummer, Karlbaum and Wien on a suitable standard or unit of light emission and those of St. John on emissive powers of substances. Methods depending on melting point of platinum are unsatisfactory. Lummer and Karlbaum unit is amount of light emitted from 1 square centimetre of glowing platinum foil, heated by current from a secondary battery. Temperature is fixed by an interesting absorption method. In this element the unit can be fixed to an accuracy of 1 per cent. St. John makes comparative determinations between brightness of a hot platinum surface and that of same platinum coated with a metallic oxide at the same temperature. Platinum temperature 1,200 degs. C. Taking the brightness of the plain platinum foil for a given wave length as unity, that of other surfaces was only found to vary from 0.987 in the case of didymium oxide to 1,017 in the case of lanthanum oxide. It is stated that the fact that the rare earths investigated, behave in accordance with Kirchhoff's law is fatal to the suggestion which has been made, that they have a specific luminosity or power of emitting, in the form of light, a part of the energy absorbed in the formation. The emissive power of platinum taken as unity, that of lanthanum oxide is found to be 2.15 and that of zirconium oxide as high as 3.15.—Lond. "Electrical Review," May 14, 1897.

ON THE MAGNETIC CHARACTERISTICS OF THE NEWER KINDS OF IRON AND THE STEINMETZ CO-EFFICIENT OF MAGNETIC HYSTERESIS.—By Dr. A. Ebeling and Dr. Erich Schmidt. This article embodies results obtained from experiments at the Reichsanstalt. Part I. tends to show that cast steel of high magnetic value is now being generally produced; while Part II. treats of the Steinmetz co efficient of magnetic hysteresis. From the tables given in the first part the authors find the fact verified that a magnetic material is not defined by one only of the quantities hysteresis, permeability, coercive force, etc., because two materials may coincide exactly in respect to any one of these quantities, and yet differ entirely in respect to the others. In their determination of magnetic homogeneity or non-homogeneity, the authors find the method of electric conductivity to be the simplest, the variation of which is determined along a so-called test-bar. It is stated that in every case the results obtained show that electric and magnetic homogeneity are coexistent attributes. In Part 2 it is stated that according to Steinmetz the factor should for the same material be independent of the chosen value B. They find, however, that if the different values of n are calculated for the values B 1.6 and E determined by Steinmetz, considerable variation is observed. In one table they show such a variation of more than 20 per cent., and they quote Steinmetz to the effect that the variation will in reality be still greater.—"Electrotechnische Zeitschrift," May 13, 1897.

Motor Carriages:

MOTOR TRAFFIC: TECHNICAL CONSIDERATIONS.—By Sir David Salomons, Bt. A paper read before the Society of Arts, May 12, 1897. A popular article which, however, contains valuable suggestions to motor carriage builders, particularly, as to the use of springs, rubber and pneumatic tires, etc. The electric motor in respect to its use on vehicles is thus summarily disposed of. "The electro-motor offers certain advantages, inasmuch tnat it is easy to stop and start, for accumulators possess a reserve power similar to the steam engine, but may be at the risk of wearing the accumulator. Of course, if larger electro-motors or other forms of engines were carried than are necessary, some of the difficulties pointed out would be greatly reduced, but practical consideration, such as expense, great additional weight, bad economy in working bar such a procedure,"—"Industries & Iron," May 14, 1897.

Miscellaneous:

EXPERIMENTS UPON PROPELLER VENTILATING FANS, AND UPON THE ELECTRIC MOTOR DRIVING THEM.—By William George Walker. First installment of a paper read before Institution of Mech. Engrs. Author refers back to a paper of his read in 1892, describing experiments on the arrangement of the surface of a screw propeller; and to some experiments made with air propellers in order to try the effect of the thickness of the blades. In the present paper he describes experiments made with a view of ascertaining (1) whether this kind of fan follows the ordinary laws respecting the mutual relations of speed of fan, power absorbed, and amount of air discharged; (2) the general characteristics regarding the speed of fan, power absorbed, and quantity of air discharged, with different angles of the blades; (3) the effect of fans differing from one another only in the cross section of their blades. Author states that experiments on the propeller ventilating fans showed that the relations of speed of fans, power absorbed and air discharged are in accordance with the ordinary laws. The experimental apparatus consisted of seventeen three-bladed fans, all 22¾ inches in diameter, especially constructed for these experiments. A table showing the various sections is given. The fans were driven by a 1-3 horsepower motor. All the results given in the paper are with fans having a free discharge, the outlet being practically equal in area to the inlet of the fan. The air was delivered through a sheet iron tube 24-inch bore and 4-inch long. Elaborate tables of the experimental results are given.—London "Electrical Engineer," May 14, 1897.

THE INFLUENCE OF SYNCHRONOUS MOTORS ON THE POWER FACTOR OF POLYPHASE CURRENT CENTRAL STATIONS.—By R. Klasson. A series of tabulated experiments, made at the power house of the imperial powder factory at Ochta near St. Petersburg by the author, with the object of modifying the troublesome lag produced in a polyphase generator circuit supplying many lightly loaded synchronous motors. The polyphase circuit of the powder factory shows during the day an exceedingly low power factor, namely, 0.6 to 0.65, this being due to the fact that during the day, motors exclusively are run from its lines. To decrease the lag the author experimented with the introduction of a synchronous motor on the lines and found the efficiency of the generator was thereby greatly increased, while the line loss

(other things being equal) was greatly diminished.—"Electrotech. Zeits.," May 13, 1897.

Power Transmission:

THE ALUMINUM WORKS AT FOYERS.—A descriptive and well illustrated article on the aluminum works erected on the banks of Loch Ness near Inverness below the Falls of Foyers. The Foyers fall is one of 350 feet, while Niagara has but 120 feet and Neuhausen on the Rhine only 65 feet. Water is taken from the River Foyers, three-quarters of a mile above the factory passing here into the first intake and flowing through a tunnel half a mile in length to the penstock chamber, where it passes down six lines of pipes to the turbines. The tunnel is remarkable for being straight for its entire length, there being not more than a foot drop from one end to the other, the great fall of water being obtained in the pipes between the last penstock chamber and the factory. When the water supply arrangements have been completed the water storage will be equivalent to 3,600,000,000 gallons. Each turbine is designed for 700 brake horse power at 140 r. p. m., with a 350-feet fall. Diameter of turbines from one side of vanes to the other about 10 feet. Vertical shaft is of steel 8 inches in diameter and runs in a step bearing. Armature on its upper end weighs 14 tons. Turbines were built by Escher, Wyss & Co., of Zurich; dynamos by the Maschinenfabrik Oerlikon. Magnet frames are of soft cast iron supported by iron columns. There are 24 poles on each machine. Winding of armature is multipolar drum. Commutator which is 6 feet in diameter has 216 segments; 120 brushes are employed. Lighting plant consists of a small lighting dynamo driven by a Pelton wheel. At present four generators are used for aluminum purposes, the fifth for calcium carbide.—London "Electrical Review," May 14, 1897.

Telegraphy, Telephony, Etc.:

RAPID CABLE LAYING FOR WAR PURPOSES.—By Lieut. Crutchley, R. N. R. & C. Scott Snell. Paper read before Royal United Service Institution, April 28, 1897. Describes a method whereby a submarine cable can be safely laid at any rate of speed within the compass of the fastest cruiser. It is thus made possible for a naval commander in chief to have at his disposal the means of establishing telegraphic communications with an outlying picket of ships at a distance of 300 to 500 miles at the speed of the fastest warships yet constructed. The paper is well illustrated, the mechanical contrivances are carefully described and the method fully explained.—London "Electrical Review," May 14, 1897.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 22, 1897.

Alarms and Signals:—

BURGLAR ALARM. H. M. Sutton and W. L. Steele, Dallas, Tex., 584,798. Filed October 29, 1895.
Provides means for alternating the current at frequent intervals, and at the same time changing or shifting the current automatically from one set of lines to another.

AUXILIARY FIRE ALARM SYSTEM. R. E. Alexander, Yonkers, N. Y., 585,072. Filed October 31, 1895.

ELECTRICAL ALARM FOR DOOR LOCKS. P. V. Vandevelde, Corona, N. Y., 585,138. Filed April 6, 1897.
Details of construction.

Conductors, Conduits and Insulators:—

COMBINED BRACKET AND INSULATOR. G. W. Mead, Shellsford, Tenn., 584,823. Filed December 21, 1896.
A combined bracket and insulator screwed into the support, and a brace connected to the support and the bracket.

ELECTRIC CONDUCTOR. I. W. Henry, New York. 584,936. Filed September 15, 1896.
A submarine conductor comprising a conducting core inclosed within a sheath of waterproof insulating material, an inclosing sheath of fibrous material, and an armor composed of non-magnetic wires side by side.

TIELESS INSULATOR. R. Delery, New Orleans, La., 585,026. Filed January 11, 1897.
The wire is held by screwing between a two-part insulator.

Dynamos and Motors:—

BRUSH HOLDER FOR DYNAMOS. J. H. Yearsley, Philadelphia, Pa., 584,912. Filed April 8, 1897.
Details of construction.

Electro-Metallurgy:—

APPARATUS FOR ELECTRIC THERMAL TREATMENT OF METALS, ORES, ETC. G. D. Burton, Boston, Mass., 585,019. Filed November 30, 1896.
Devices for maintaining, directing and regulating the flow of a stream of an electrolytic solution; also for maintaining the solution at the required heights in the tanks and wells; also for supporting the articles to be acted upon and for supplying them with the required electric currents.

METHOD OF MELTING IRON BY ELECTRICITY. C. G. P. De Laval, Stockholm, Sweden, 585,040. Filed October 3, 1892. See page 747, June 30, 1897.

APPARATUS FOR ELECTRODEPOSITION OF METALS. A. S., T. A., R. J. and S. Smith and T. Deakin, Walsall, Eng., 585,051. Filed August 27, 1896.
The articles to be treated are placed within a revolving barrel, supported within the electrolytic bath, and during the time that the deposition of the metal is taking place, subjected to a rolling over and over, or shaking process, which completely polishes brilliant their surfaces.

Lamps and Appurtenances:—

ARC LAMP CARBON. T. M. Foote, Chicago, Ill., 584,867. Filed February 17, 1896.
The carbon has a groove or slot from the circumference to the center, running its full length.

ELECTRIC ARC LAMP. A. Bureau, Brussels, Belgium, 584,983. Filed January 27, 1897.
Details of arc lamp mechanism.

MULTIPLE FILAMENT REGULATING INCANDESCENT LAMP. C. Truitt, Columbia, Mo., 585,137. Filed February 15, 1897.
A socket so arranged that by rotating the lamp, one filament is cut in after the other.

Miscellaneous:—

ELECTROMAGNET. C. P. Bostian, Milton, Pa., 584,848. Filed April 22, 1897.
Uses a core having perforations therethrough and inserting in the perforations insulated soft iron rods.

THERAPEUTIC ELECTRIC CURRENT GENERATOR. E. W. Chellis, Erie, Pa., 584,853. Filed May 5, 1897.
A spring-driven magneto, in a pocket case, wound like a watch.

ELECTROTHERAPEUTICAL APPARATUS. F. J. Patten, New York, 584,957. Filed September 30, 1896.
Designed to lessen the shock of the current.

VALVE APPARATUS F. Gray, Chicago, Ill., 585,094. Filed January 4, 1897.
An electrical circuit maker or breaker is employed to automatically open or close the circuit for any given purpose or the momentary pressure is relieved without opening the valves fully. For use in conjunction with automatic fire sprinkler systems.

Railways and Appliances:—

TROLLEY. W. J. Smith, Gloucester City, and W. G. Johnston, Woodbury, N. J., 584,831. Filed August 5, 1896.
A self-oiling trolley wheel, and other details of construction.

ELECTRIC RAILWAY. F. W. Hunter, Cranford, N. J., 584,873. Filed November 17, 1896.
Employs the rails as the return and two parallel conductors of similar polarity within the conduit disposed relatively to each other and to the slot of the conduit that they come upon either side of the vertical plane dropped down from the slot.

ELECTRIC RAILWAY SYSTEM. G. Westinghouse, Jr., Pittsburg, Pa., 584,911. Filed November 26, 1892.
The trolley is a cylinder having a number of grooves. The trolley wire has yielding supports.

ELECTRIC RAILWAY TROLLEY. E. M. Bentley, New York, 584,918. Filed June 4, 1896.

CONDUCTOR FOR UNDERGROUND ELECTRIC RAILWAYS. C. Peterson, San Francisco, Cal., 585,047. Filed January 29, 1897.
Consists in the novel construction of concaved insulated conducting plates arranged longitudinally within a tunnel, so as to form contacts for trolleys connected with the car.

INSULATED SUPPORT FOR CONTACT RAILS. A. Hanson and J. R. Chapman, Chicago, Ill., 11,613. Reissued. Filed March 24, 1896.

Switches, Cut-Outs, Etc.:—

AUTOMATIC SWITCH FOR ELECTRIC CIRCUITS. R. Belfield, London, Eng., 584,843. Filed June 19, 1895.
Automatically operates whenever the current in the controlling circuit becomes either greater or less than a certain predetermined value. The further object is the provision of a method whereby either the primary or the secondary of a transformer in a distant station may be instantly cut in or out.

CONTROLLER FOR ELECTRIC MOTORS. H. P. Davis, Pittsburg, Pa., 584,856. Filed October 28, 1896.
Details relating to an elevator controller.

MAGNETIC CIRCUIT BREAKER. W. E. Harrington, Philadelphia, Pa., 585,030. Filed December 26, 1895.
The cut-out switch is actuated to sever the connection of the circuit with a rapidity bearing an inverse ratio to the amount of excessive current flowing through the circuit.

Telephones:—

TELEPHONE TRANSMITTER. R. S. Barnum, Chicago, Ill., 584,810. Filed July 9, 1896.
Special construction to avoid packing.

TELEPHONE-ANNUNCIATOR, CALL-BELL and FIRE-ALARM. M. Garl, Akron, Ohio, 584,819. Filed April 6, 1895.
Details of construction.

TELEPHONE. J. T. Gent, A. W. Staveley and I. H. Parsons, Leicester, Eng., 584,868. Filed December 11, 1895.
The microphone is rotated when the receiver is removed from the hook, to prevent packing.

TELEPHONE BRACKET A. Y. Gordon, Masillon, Ohio, 584,871. Filed November 27, 1896.
Details of construction.

PERSONAL

MR. A. C. SHAW, business manager of The Electrical Engineer, sailed for Glasgow on July 3, by the City of Rome, for a short holiday.

MR. R. T. LINCOLN has been elected president pro tem. by the Chicago Telephone Company, as successor to Mr. H. B. Stone.

MR. W. A. JACKSON, who has been vice-president and

general manager of the Central Union Telephone Company, has been elected its president. As a pioneer telephonist he is well known throughout the electrical field.

PRESIDENT INSULL, of the National Electric Light Association, was in New York City last week on important business in connection with its work.

MR. F. C. PHILLIPS, under whose wise and able management the Elwell-Parker Electric Company, of Cleveland, has been slowly but surely coming to the front, was a busy visitor to New York last week, staying over the Fourth.

MR. F. H. WEBB, on his retirement from the secretaryship of the London Institution of Electrical Engineers, was given a complimentary dinner at which Lord Kelvin presided.

MR. JAMES F. HEYWARD, general manager of the City and Suburban Railway, Baltimore, will, on July 6, become assistant to the president of the United Traction Company of Pittsburg, Pa. He will retire from his present position on July 1, when all the duties of that office will be handled by Vice-President and General Manager House, of the Consolidated Railway, formed by the consolidation of the City and Suburban and the Traction Company. Mr. Heyward was elected secretary of the Consolidated Railway, but owing to his active disposition and experience in the operating department, he considered the duties uncongenial and resigned.

THE STOCK MARKET

GENERAL STEADINESS.

BUSINESS was interrupted more or less during the past week by preparations for the long holiday around the Fourth, and will not again resume normal activity till the summer vacations are over; but there is no change in the general sentiment of confidence and steadiness developed before the month began. Even with a large strike threatening in the coal industry, values have not gone off at all, whereas a short time ago, the mere rumor of it would have sufficed to render everybody nervous and depressed. The country has gone through too much to worry about a little thing like that.

Of Western Union last week there were sold 37,276 shares at prices up to 85. General Electric sold to the extent of 12,340 shares up to 35. American Bell is not selling in large blocks, but stays easily around 230.

COPPER is quoted at 11½ Lake, and 11¼ Western, firm.

STEEL RAILS, heavy section, are quoted $19 and upward; light rails, $24 to $28.50.

MAGNOLIA METAL quotations are furnished us as follows: Magnolia anti-friction metal, 25c. per lb., f. o. b. N. Y. or Chicago; No Name metal, 18c. per lb., f. o. b. N. Y. or Chicago; Mystic metal, 8c. per lb., f. o. b. N. Y. or Chicago.

TRADE NOTES & NOVELTIES

WESTINGHOUSE PLANT FOR THE SOUTHERN UNION DEPOT, BOSTON.

Although it is only a week since the Westinghouse Electric and Manufacturing Company made the announcement that they had obtained an enormous contract of power transmission apparatus for fifteen 5,000 h. p. generators from the St. Lawrence Construction Company, of New York, the Westinghouse people have now secured another order for electrical apparatus which, while not so large, is of equal importance. This is a contract from the Boston Terminal Company, which is now constructing the Southern Union Depot, at Boston, Mass. It is the intention of the managers of the new Union Depot not only to handle the largest number of trains entering any station in the world, but to handle them in the most complete and efficient manner.

All the modern devices of interior motive power for heat, light, electric power, signaling, elevator work, refrigeration, ventilation, etc., will be taken advantage of in the equipment of this gigantic undertaking and the Westinghouse interests have obtained the entire contract for doing all this work. In this fact lies the most important feature of the contract because it was found by the management that it was necessary in order to obtain uniform work to put the entire matter into the charge of one firm; and as the Westinghouse interests as manufacturers of steam engines, electrical machinery and signaling apparatus were the only firms bidding for this work in a position to undertake it all, the management of the Terminal Company decided for that reason to entrust the Westinghouse Companies with the work. In this connection President Charles P. Clark, of the New York, New Haven & Hartford R. R., says: "We awarded the contract to the Westinghouse Companies because they are the only concerns that cover the whole field. Any subdivision for the engineering of construction the company will attend to, and thus it should be able to connect and centralize all the heat, light and power economically. We expect to be in the new Union station in 1898."

It is understood that this contract amounts to over half a million dollars. The whole contract was made directly with Westinghouse, Church, Kerr & Co.

BALL ENGINES IN THE LIGHTING FIELD.

One of a comparatively few strictly high grade engines for electrical purposes is the Ball automatic engine, built by the Ball Engine Company, Erie, Pa. This engine's beginning was almost identical with that of the electric light business, and there are many stations where Ball engines that have been running from ten to fifteen years are giving good satisfaction to-day. The present management, with the experience of fifteen years building engines for electrical purposes, have brought the engine to the highest degree of perfection, and we are glad to learn that the extensive works of this company are very busy. In addition to their extensive business all over this country, they are shipping a number of engines to foreign countries.

MR. C. A. COFFIN ON THE SITUATION.

In a recent interview, Mr. C. A. Coffin, of the General Electric Company, said: "I am not a boomer, but I do know that our own business reflects very accurately the condition of the country. A year ago we were suffering, as were most manufacturing enterprises, from disturbed political and financial conditions. Now we are actively employed in every department, and our business is growing. My idea is that recovery is slowly but surely coming. The recovery will be substantial and solid. I can tell this in part from the volume and character of our purchases. We consume great quantities of copper, iron and rubber. These, in the order named, are the materials of which we use the most. Our purchases of each of them are far larger than they were a year ago. There is more money in circulation every day. Capital is coming out, ready for investment. Labor in all its branches is finding paying employment.

"In my opinion the certainty that Congress is going to pass the tariff bill has lent a great impetus to business. The settlement of the tariff for a good long time to come will enable business to adjust itself to conditions that may be considered as comparatively certain. As soon as the tariff bill is passed I think that Congress should adjourn and go home."

TARIFF ON LAMPS.

The schedule on incandescent lamps in the new tariff bill now in the United States Senate places the duty at 35 per cent. ad valorem.

BELL TELEPHONE OUTPUT.

The instruments statement of the American Bell Telephone Company for the month ended June 20, shows: Gross output, 17,586; returned, 7,998; net output, 9,588. From December 21 to June 20 the showing was: Gross output in 1897, 111,919, against 114,094 in 1896; returned, 44,606, against 43,177; net output, 67,313, against 70,917; total outstanding 839,602, against 745,983 in 1896.

NEW ENGLAND NOTES

PRESIDENT EUGENE PHILLIPS, of the American Electrical Works, has issued his usual memento of the Fourth in the shape of a beautiful edition de luxe of the Star Spangled Banner, in colors, with a picture on the cover of the flag waving over the fort in the morning light.

THE WILLARD AUTOMATIC sectional third-rail system described elsewhere in this issue is being placed on the market by the Willard Third Rail Company, of 34 School street, Boston, Mass.

MR. J. ORNE RYDER, Salem, Mass., notifies us that he has severed his connection with the Crown Woven Wire Brush Company, of that place, and has resigned as secretary and treasurer, so that he will have no further interest in the company.

NEW YORK NOTES.

MR. T. J. MONTGOMERY, of the T. J. Montgomery Company, Fulton street, New York, has sailed for England. He will look into European conditions in the tool and machinery trade. A large demand for their beautiful and useful publication, "The Tool Catalogue," has sprung up all over the world.

DALE MANUFACTURING COMPANY, Greenwich street, are sending out their new catalogue, of which they have issued 20,000. The book shows artistic designs of their latest productions in gas fixtures. The catalogue shows Dale Manufacturing Company's entire line and will be sent to any address upon application.

MR. M. R. RODRIGUES, 17 and 19 Whipple street, Brooklyn, N. Y., has issued a neat little folder giving some useful elementary data as to electricity and the use of batteries and motors.

A NEW TELEPHONE SHOP is to be built on Gold street, this city, by the New York Telephone Company and Robert Goelet. It will be eight stories brick, and will cost $175,000.

STATEN ISLAND.—The New York and Staten Island Electric Company are erecting at Livingston, Staten Island, a new power house of modern construction. The walls of the building are brick and the roofs have steel trusses covered with corrugated iron. The roofs are arranged with suitable monitors with skylights for light and ventilation. On the building is a large wire tower of steel construction. The engine room is arranged for a traveling crane of 15 tons capacity. The building has been constructed with the idea of having it absolutely fire-proof and arranged in an up-to-date manner. The roof of the engine and dynamo portions of the building is lined underneath the corrugated iron with the Berlin Iron Bridge Company's anti-condensation fire-proof roof lining. The Berlin Company have the contract also for furnishing and erecting all the steel framework and covering for the plant.

PIERCE & MILLER ENGINEERING COMPANY.—Mr. Frank M. Pierce, president of this company, informs us that on June 12, 1896, before starting on his trip around the world he purchased from J. D. Miller the small stock interest he then held in the company, and that Mr. Miller is no longer connected with the company.

WESTERN NOTES

H. M. UNDERWOOD & CO., the Marquette Building, Chicago, state that the factory where their lamp guards are manufactured was burned on the 28th ultimo. This was very unfortunate as a stock of 200 gross of the guards which were ready for shipment, as well as all the tools and machinery used in their manufacture were destroyed, and Mr. Underwood further states that he does not expect they will be able to fill any orders for two or three weeks. The firm will not sustain any loss by the fire outside of the delay which they will be put to in supplying their orders.

THE F. AND L. FLUSH PUSH BUTTON SWITCH is the Electric Appliance Company's latest specialty. This switch is a very simple and compact device, the size of the face plate being no larger than an ordinary two button gas key. The face plate is nickel plated with pearl buttons. One of the merits of the switch is the ease with which it is operated. The Electric Appliance Company are enabled to offer it at even a lower price than the regular snap flush switch. It is at present made only in single pole style, with a capacity of 5 amperes, although other sizes and capacities are now in preparation.

THE WILLARD ELECTRIC AND BATTERY COMPANY, of Cleveland, O., having had such great success with the Willard type of storage battery, are now placing on the market a new concentric accumulator which is very light in weight and especially adapted for horseless carriages, and which is also moderate in price.

MR. C. H. WILMERDING, with a competent staff, has taken up the management of the Crocker-Wheeler Co.'s business in this territory, his offices being in the Old Colony Building. His knowledge of electrical affairs in Chicago and the West makes him a very useful man, while his professional position guarantees the highest quality of service and results.

PHILADELPHIA NOTES

THE BALL ENGINE COMPANY, Erie, Pa., is building two 125-horse-power horizontal tandem compound engines, which will be used for the electric transmission of power and light in a large works in the city of Moscow, Russia.

MISCELLANEOUS.

THE TESTING OF AUTOMATIC MAGNETIC CIRCUIT BREAKERS.[1]—I.

BY C. M. CLARK and C. W. MACMULLEN.

SAFETY devices have long been essential elements of electric light and electric power systems, and among these instruments, the circuit breaker occupies a most important place. Its function is to interrupt the circuit, when the current in that circuit has risen to such an abnormal amount that it threatens to injure or to burn out the instruments or the conductors.

The first practical method of breaking the circuit was by means of a fuse. The following inherent faults of fuses have militated against their success: 1. Deterioration caused by (a) Recurring abnormal currents; (b) Oxidation from various causes. 2. The ability of the fuse to carry current in excess of its rated capacity, for a time sufficient in some cases to cause damage to conductors and apparatus. Another objectionable feature of fuses is the trouble of replacing those that are burned out.

In the automatic magnetic circuit breaker these faults are lessened and in some cases eliminated. Its most important features are: 1. Time element, i. e., the time of opening the circuit decreases as the conditions approach a short circuit. 2. Positiveness in opening. 3. Constancy and accuracy.

The current rises to a considerable strength in the case of

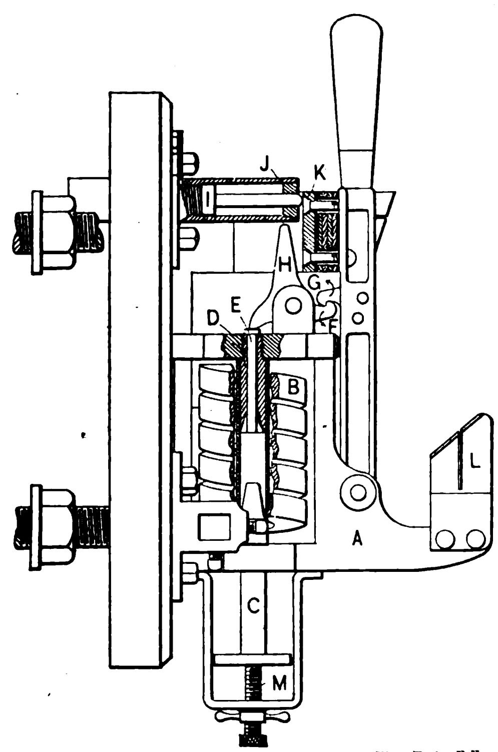

FIG. 1.

an overload on the circuit breaker, before the instrument acts. In most cases, however, a certain time element or capacity for heat is desirable, because the conductors and apparatus also have heat capacity, and it is not necessary to break the circuit if the current only momentarily rises above the normal.

On acount of these valuable features, the magnetic circuit breaker has steadily grown in importance, and has, in many cases, replaced the fuse. Data relating to the practical working of these instruments will be of value to those engaged in the application of electricity to light and power. It is for this reason, therefore, that the following investigation was undertaken. The circuit breakers tried in this test were of the well known I. T. E. type, made by the Cutter Electrical and Manufacturing Company, of Philadelphia.

This circuit breaker acts on the solenoid principle. The main current of the circuit passes through a coil of low resistance, B, Fig. 1. When the current has risen to a specified value, the movable plunger, C, is attracted up into the coil,

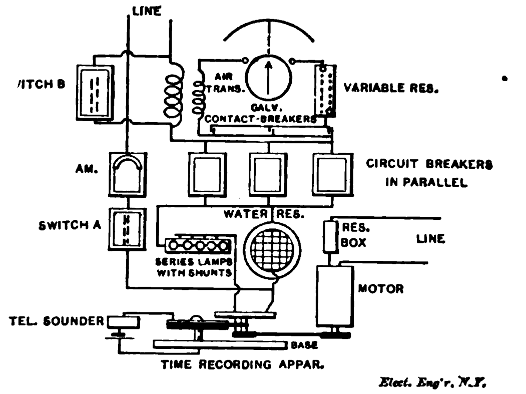

FIG. 2.

impinging against the "striker pin," E. This pin actuates the striker plate, which, in turn, releases the catch, G, of the switch arm. At the same time the switch arm is forced out by the spring piston, I, thus breaking the circuit. This instrument may be set to act at any stated current, within its range, by adjusting the screw, M, until the plunger is in the required position.

Our method of experimenting may be described by the following specific example. The circuit breaker is set at 15 amperes, i. e., it will break the circuit, when the current in that circuit rises to 15 amperes, approximately. Now, let a current exceeding 15 amperes by a certain definite amount be imposed on this circuit. It is required, first, to find how high the current rises above the set value of 15 amperes, and; second, to find the length of time taken by the circuit breaker to act.

The determination of these two values, the maximum strength of current and the "time factor," was the object of the following tests. Three sets of readings were taken for each setting of the instruments. In the first set of readings the current imposed on the circuit was so adjusted as not to exceed an overload of 50 per cent. in excess of that for which the instrument was set. In the second series of readings the overload was not allowed to exceed 75 per cent., and in the third set of readings there was practically a short circuit. By applying this method of reading to every setting of the instrument, values for the maximum current strength and "time factor" were obtained.

Apparatus for Determining Maximum Strength of Current. —In this apparatus the principle of mutual induction was utilized. The primary coil of an air core transformer was introduced into the main circuit, in series with the circuit breaker. The magnetic field produced by the current in the primary coil is proportional to the current. Now, when the field of the main current is building up, the lines of force of this field cut the secondary coil, inducing in it an e. m. f. proportional to the variation of the lines of force, and causing a deflection of the galvanometer. Since the variation of the lines of force of this field is proportional to the current in that circuit, by placing a ballistic galvanometer with large period of vibration in series with the secondary coil above mentioned and properly calibrating it, a reliable method for determining the maximum strength of the current by the deflection of the galvanometer was obtained. This method was suggested by Dr. M. I. Pupin.

Calibration of the Galvanometer.—Known currents, differing in strength, were successively impressed on the primary circuit, and the deflections due to each were recorded. These currents were chosen with reference to the range of action of the circuit breakers tested. Definite resistances were added to the galvanometer circuit, when necessary, in order to keep the deflection within reasonable limits.

[1]Graduation Thesis, Columbia University., 1897.

When the tests for determining the current strength were made, the added resistance in the galvanometer circuit was made the same as the resistance in some particular one of the calibration tests. By this means a direct proportion was obtained between a known current with a known deflection, and an unknown current with a known deflection. The solution of this proportion gave an accurate indication of the maximum strength of current in the primary circuit under any specified conditions.

Apparatus for Determining the "Time Factor."—The apparatus for determining the time factor consisted of a wooden disc revolving in suitable bearings, and driven by a small motor. The upper surface of this disc was covered with a layer of tin foil. On the tin foil was placed a circular piece of blotting paper of the same diameter. The blotting paper had been previously soaked in a solution consisting of 1.5 oz. red prussiate of potash, 0.75 lb. nitrate of ammonia, 0.5 lb. chloride of ammonia, and 1 gallon of distilled water. Part of the main current was shunted and made to pass through the chemically prepared paper, as it revolved. This was made possible by means of a sliding contact shown in the accompanying diagram, Fig. 2. The sliding contact was a thin iron rod, which pressed against the revolving disc—iron being a necessary factor in the chemical reaction which takes place on the passage of the current. The current in the shunt, passing through the chemically prepared paper, decomposes the compound at its point of contact with the iron rod, forming Prussian blue. When the disc revolves, and the current is allowed to flow, a blue circle is traced on the paper. The speed of the disc was so adjusted with respect to the duration of the current that an arc of the circle was produced on the paper.

The radius of the circle of which this arc formed a part, was carefully measured; the length of the chord belonging to the arc was also carefully determined. The speed of the disc was obtained in the following manner: A rubber belt was passed from the shaft on which the disc revolved, around a wheel whose diameter was so much larger than the shaft, as to make it revolve at 1-16th the speed of the disc. The time during which this wheel made a certain number of revolutions was taken, and by proper calculations the speed of the disc was obtained.

The stretch of the rubber band would have introduced an error had not the load on the shaft been inappreciable. The speed of the disc, the length of the chord and the radius of the circle being known, an accurate determination of the time factor was obtained. With properly constructed apparatus the time can be measured to within one-ten thousandth of a second, with a fair degree of accuracy. The methods here described were first applied to a carbon contact circuit breaker of the standard switchboard type, shown in the accompanying diagram. The range of this instrument was from 15 to 40 amperes. Its resistance was found to be 0.05 ohm.

Description of Circuits.—As shown in the diagram, the current from the dynamo first passes through the air core transformer, then through the circuit breakers which are arranged in parallel, so that any desired one may be placed in the circuit. From the circuit breakers the current passes to a water barrel resistance, and thence through a switch and ammeter, A, back to the dynamo. Shunted around the water barrel is a circuit which is used to determine the time. This current passes through an iron rod which presses on the chemically prepared paper. A series lamp board is used in this circuit to alter the resistance as desired. The paper is placed on the revolving disc which is covered with tin foil, thus completing the circuit as indicated by the dotted lines.

From the above mentioned disc, a similar disc is rotated by reduction gearing, and in connection with this a battery circuit with sounder, a sliding contact completing the circuit. Thus, the revolutions of the disc can be counted. The speed of the motor was regulated by the variable resistance, as shown in the diagram. A switch, B, was used to shunt the air transformer, to protect it from overheating, when it was necessary to have quite a large current on for some time during the setting of the different instruments.

The galvanometer circuit includes a large number of turns on the air transformer, contact breakers and a variable resistance.

A contact device was placed on the handle of the circuit breakers by means of which the galvanometer circuit was opened just prior to the interruption of the main circuit by the circuit breakers. This was necessary; otherwise a large "back-kick" by the galvanometer would be obtained.

Since the curve representing the rise in current is very flat near the top, any slight error in breaking the galvanometer circuit too soon, would make only a very slight error in the results. In making the experiments, the "contact breakers" were very carefully adjusted so as to avoid a "back-kick."

The function of the variable resistance was to make the deflection of the galvanometer about the same, no matter what strength of current passed through the transformer. We see, by this arrangement, that the galvanometer deflections are proportional to the lines of force produced by the primary circuit, which, in turn, are proportional to the maximum strength to which the current (in the primary circuit) rises.

The resistance of the "water barrel" was arranged so that the desired current would flow through the circuit, the strength being read by means of the ammeter. Everything being ready, the switch, A, was opened, and when the galvanometer was at rest, the circuit was closed by means of the switch, A, and the maximum swing of the galvanometer was noted; readings of the ammeter being then taken to see that the conditions of the circuit had not changed. This was repeated with different strengths of currents, the resistance of the galvanometer circuit being changed to correspond.

STORAGE BATTERY ENGINEERING PRACTICE.—XVII.

BY JOSEPH APPLETON.

(COPYRIGHT, 1897.)

STORAGE BATTERIES IN EDISON STATIONS—(Continued).

THE cell regulating switches are illustrated in Fig. 66. There are four of these switches in all, arranged in two pairs on each side of the three-wire system. Each switch has thirty contacts with a carrying capacity of 2,000 amperes. The

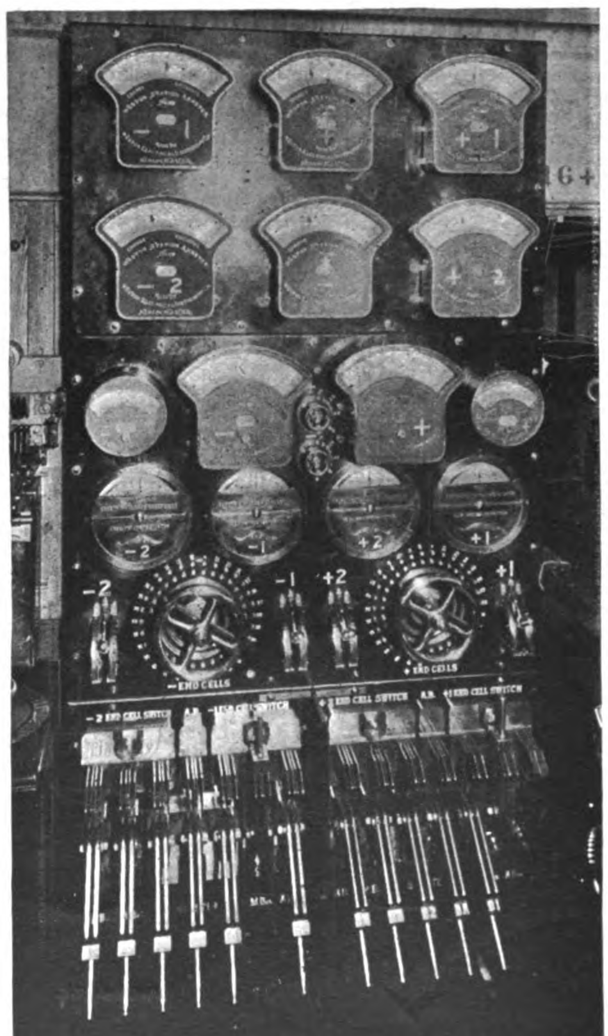

FIG. 67.—BATTERY SWITCHBOARD PANEL, PHILADELPHIA EDISON STATION.

general design of these switches is the same as described and illustrated in Fig. 40, except that they are operated by motors. A ½ horse-power Lundell motor is connected by worm gearing to the screw on which the contact brush travels. The po-

sition of these brushes is shown on the main switchboard by means of mechanical indicators operated by light shafting and bevel gearing connected to the switch screws. These indicators are shown in detail in Fig. 69. The cell regulating switches are so arranged that the two motors on each pair can be coupled together and the two switches operated as one; this is done when the battery is discharged at the maximum rate which is equal to the combined capacity of the pair of switches.

The battery switchboard is shown in Fig. 67. It consists of three enamelled slate panels mounted on an angle iron frame. On these panels are mounted the following apparatus in dupli-

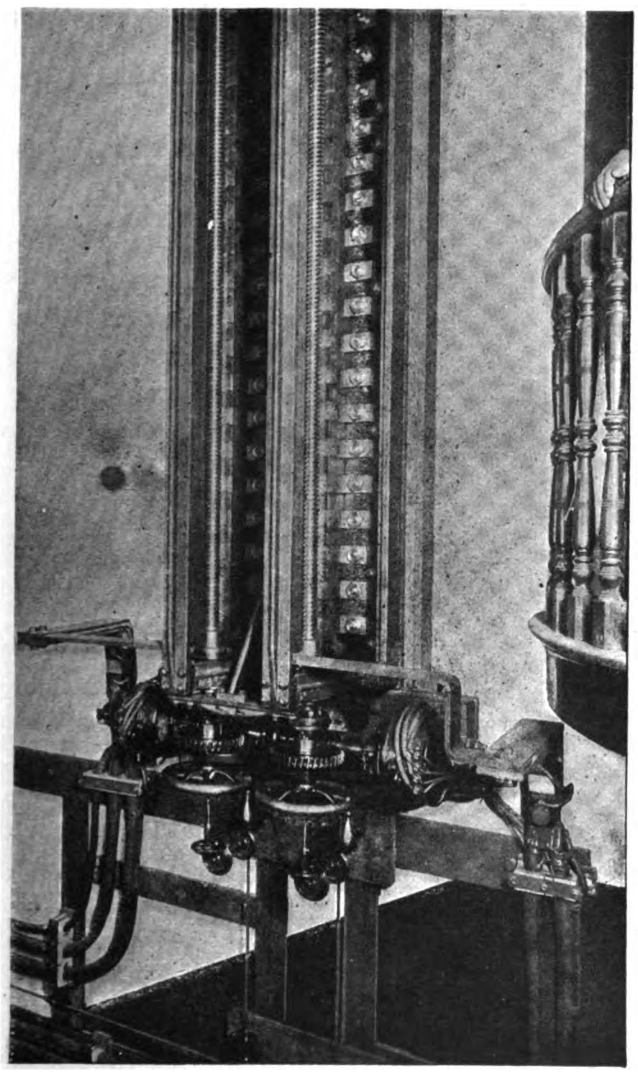

FIG. 66.—END CELL SWITCH, PHILADELPHIA EDISON STATION.

cate, one set for each side of the three-wire system: two motor control switches; two cell regulating switch indicators; two ammeters for cell regulating switches; one ammeter for battery neutral; one voltmeter with five point switch to read pressure on the two busses, the two-cell regulating switches and the charging buss; one low-reading voltmeter with 30-point switch to read the voltage of the end cells; seven knife switches to effect the various combinations described hereafter.

The switchboard is so arranged that either cell-regulating switch of each pair can be connected to the main, auxiliary and charging buss; also for the booster to be connected between the main and auxiliary busses. This combination enables the battery to be charged and discharged simultaneously; also to discharge at two pressures at the same time; also both cell-regulating switches to be connected to the same buss for maximum discharge.

The motor control switches are shown in detail in Fig. 68. They consist of five pairs of contacts arranged on the arc of a circle with a movable lever which makes the various combinations required to control the motor. The central contact is in the "off" position when the motor is entirely disconnected.

When it is desired to run the motor in the direction to cut in more cells, and raise the voltage, the lever is moved to the extreme position on the upper side. When the indicator shows that the traveling brush on the cell-regulating switch is nearing the proper position on the contact, the lever is moved down towards the "stop" position. During this movement it short circuits the armature of the motor, which is series wound, first through a resistance and then on dead short circuit, at the same time inserting in the motor circuit a resistance to keep the current normal when the armature is short circuited. When the operation of the motor is completed, the lever is moved to the "off" position. The same operation is required for cutting out cells, except that the lever is moved to the lower side of the arc.

Fig. 69 shows in detail the indicating apparatus. It consists of a dial and pointer operated by gearing from the screws of the cell regulating switches. The dial is divided into thirty divisions, and numbered accordingly, one for each of the contacts on the regulating switches. The dial moves from one division to another as the brush on the switch travels from one contact to the next; at the same time the pointer

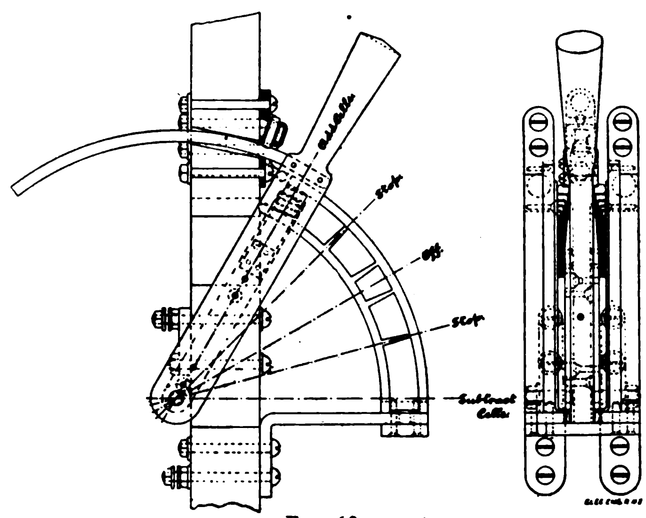

FIG. 68.

makes one complete revolution for every division on the dial. The exact position of the brush on the contact is shown by the pointer; in fact if the motor is stopped when the pointer is within two inches on either side of the zero mark, the brush is practically in the central position on the contact. This arrangement enables the cell regulating switches to be operated from a distance, and for switches of this capacity is more satisfactory than hand operation.

The low-reading voltmeter can be connected by means of the thirty-point voltmeter switches to any one of the end or regulating cells of the battery. These cells are worked unevenly, being cut in or out as required to maintain a constant voltage under varying loads, and, consequently, do not require the same amount of charge as the cells on the main battery. By means of these voltmeters and switches the condition of these cells can be ascertained at all times by the switchboard attendant, who can tell when they are fully charged and cut them out at that time. This method enables the battery to be worked at the highest point of efficiency with the least amount of attention, all the readings being obtained at the switchboard.

The ammeters are arranged as shown in the diagram of connections, viz., one on the battery neutral and one on each of the cell-regulating circuits, for the purpose of simplifying the work of keeping the records. The ammeter in the battery neutral shows at a glance what the battery is doing, while, in order to ascertain this from the ammeters on the cell regulating circuits, it would be necessary to add or subtract the two readings. For example, the battery may be charging through one switch and discharging through the other, or discharging through each at two different pressures. In both cases the net charge or discharge is shown by the meter on the neutral which is common to both circuits.

The charging of the battery is effected by means of boosters driven by compound wound motors, so wound that they will

maintain a constant speed under the varying voltage of the busses. These machines are of the same type as those illustrated in Fig. 42. All four machines are connected together by couplings so that one motor may be used to run both boosters when the charging current is light. The capacity of the booster is 1,250 amperes at 60 volts.

As a general rule this battery is operated in the following way: It carries the entire load of the station from 12.30 A. M.

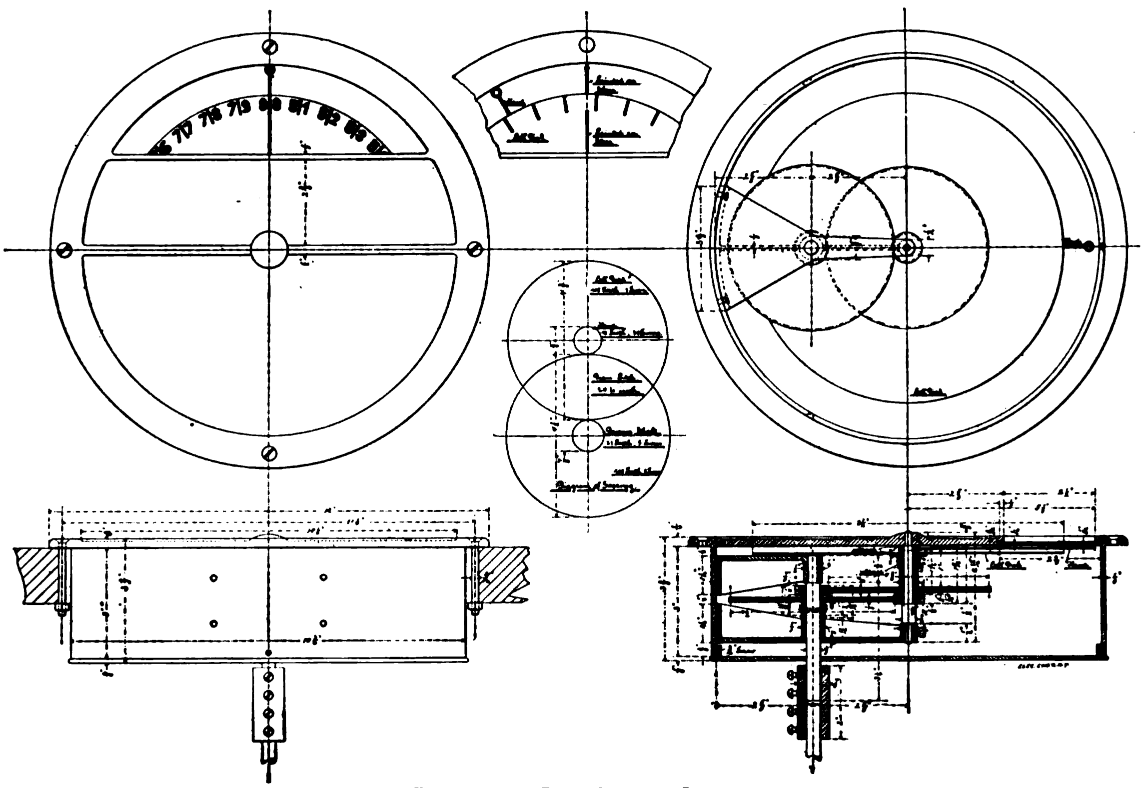

FIG. 69.—DETAILS OF CELL SWITCH INDICATOR

till 6.30 A. M., about 8,000 ampere-hours being the average capacity taken out during this time. From 6.30 A. M. on, the battery is charged, at the same time being used for equalizing the load on the generators. Between 12 M. and 1 o'clock P. M. when part of the motor load is taken off for the dinner hour, causing a drop in the load curve, the battery is charged at the maximum capacity of the boosters, bridging over this dip. By 4.30 P. M., when the peak commences to come on, the battery is full and ready to take its share of the increased load. Usually during the peak, which lasts about 1½ hours, the battery is discharged at the one-hour rate and saves this

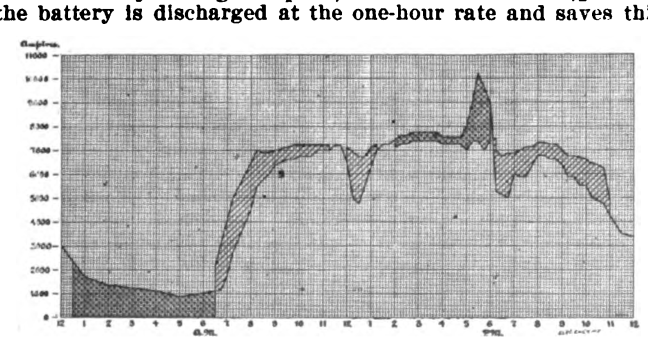

FIG. 70.

capacity in boilers, engines and dynamos being got ready and put in service for such a short time. After 6 o'clock, when the peak is over, the battery is charged again so as to be ready for shutting down all the generators at 12.30 A. M.

Figs. 61, 70, 71 and 72 show typical load curves of this station and explain the methods of operating the battery under different conditions which have been found most economical. Fig. 61 is the load curve of a maximum winter's day just before Christmas. The load reached 20,500 amperes during the peak, and the battery took 7,400 amperes of this, instead of having to get ready this capacity in generating machinery for two or three hours' use only.

Fig. 70 shows a summer's day load when the peak is very small. In this case the battery carried the entire load of the station for 6 hours, from 12.30 to 6.30 A. M. and within one hour from the time of starting up the generating plant the load reached its normal and by means of the battery the load on the generators was maintained practically constant for 14 hours, from 8 A. M. till 10 P. M.; from 10 P. M. till 12.30 A. M., when the battery would again carry the entire load, the generators were shut down as the load fell off. This load curve shows the beneficial results of a storage battery as applied to a central station and will prove intensely interesting to all engineers who are endeavoring to straighten out their load curves. These results were obtained on June 15, 1897.

Fig. 71 illustrates a Sunday load curve when the entire load of the station was carried from 12.30 A. M. till 2 P. M. by the battery, the capacity taken out of the battery being about 14,000 ampere-hours. When the generating plant was started

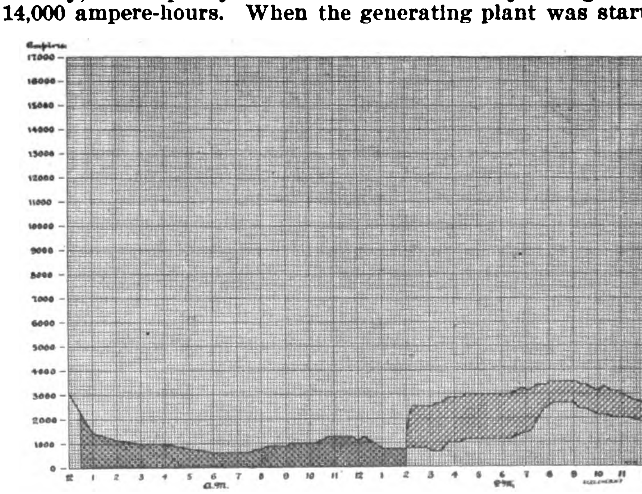

FIG. 71.

up, the battery was charged and helped to keep a constant load on the generators. In addition to this, the fact of having thirteen consecutive hours for repairs and overhauling with all machinery shut down in the station is a great advantage to the central station operation.

Fig. 72 shows the load carried by the station on a day in May, 1897, when a thunder storm occurred during the after-

noon. On this occasion the load increased in a few minutes to the amount of 6,000 amperes beyond the capacity of the generators in operation, the whole of which was carried by the battery, the pressure being kept up to normal during the entire time the increased load continued. Without a battery it would have been impossible to maintain the regular service without a drop in the voltage and candle-power. The value of a battery under these conditions cannot be overestimated.

It is impossible to get sufficient generating machinery into operation on such short notice and very uneconomical to keep such capacity in readiness for cases of emergency.

A storage battery enables the station to be run practically without any generating machinery being kept in reserve for emergency and is capable of tiding over any period of sudden

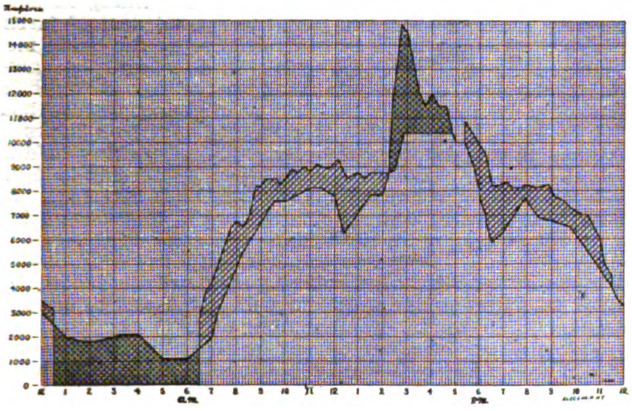

FIG. 72.

increase in load or trouble in the station till the additional machinery can be started up.

With the exception of a few weeks at Christmas time, when the load is abnormal, the battery enables, practically, a constant generator load to be maintained from between 8 and 9 o'clock in the morning, till 9 o'clock at night, between which hours no change in the capacity of the generating plant is necessary, the units running being fully loaded all the time. It is only between the hours of 6.30 and 9 in the morning, and 6 and 12.30 at night that additions or reductions have to be made in the number of units required in operation.

It is found in actual practice that the battery is equal to 2,000 horse-power capacity in boilers, engines and dynamos, this capacity being available at a moment's notice, which is not the case with the generating plant. The results obtained in this station are good, but not more favorable than can be met with in many other situations, and it only requires the managers and engineers of central stations to look more fully into the advantages occurring from a properly designed and installed battery plant before they will be considered indispensable.

ELECTRICAL MACHINE SHOP PRACTICE.—III.

BY JAMES F. HOBART, M. E.

THE babbitting of motor boxes, particularly for street railway work, is a matter the mechanical engineer has had quite a number of tussles with, and has not come off best every time, by any means. In the shop where the bearings are first lined with soft metal, and are free from old babbitt, dirt and grease, and only a few boxes have to be lined—or rather only a few kinds,—it is different from what it is in the repair shop with cars from about every shop in the country—at least so it seems. Then, there must be jigs for every kind, and the "know how" to use the jigs after they have been made.

Split boxes are comparatively easy to rebabbitt, and nothing will be said about them in this connection. But to turn out a good solid box, with perhaps an end flange or collar of soft metal, is another matter altogether.

A number of years since, the Thomson-Houston Company made drawings of elaborate collapsing mandrels for this kind of work, and after finding that it would cost several thousand dollars to equip their works with the variety of mandrels needed, I believe the project was dropped, and solid mandrels were used for box lining.

One of the best babbitting mandrels, as well as the simplest I have seen, is shown in Fig. 10, the mandrel, A, being a piece of plain shafting turned down at the ends, a and b, to fit the bearings, a, a, Fig. 11. In Fig. 10 B shows the mandrel with a pair of heads in place, head c being plain, while head d is cupped as shown to form the end collar or bearing shown at a, a, Fig. 12. In this engraving, b b, shows a section of the iron box, and c c is the usual lining to which the end collar is an addition.

In this section, and in succeeding sketches, the box is represented by a plain cylinder and all outside detail is left off, for clearness. In Fig. 13 a box is shown on the mandrel, with heads in place, all ready for pouring. When the end ring must be cast on, the head, b, must be the same diameter as the box, but when the ends are to be plain, the heads may be of any diameter, as seen at d.

When the heads are in place, a strip of tough binder's board, e, is wound around the junction between box and head, at the end where the collar is to be cast, and by means of this strip

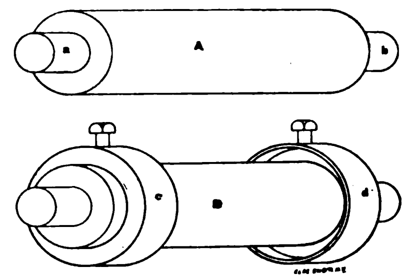

FIG. 10.—MANDREL FOR LINING SOLID BOXES.

any thickness of collar may be cast. A couple of strings, f, f, are tied around over the binder's board to hold it in place. In some shops, a neat spiral spring is made endless, and slipped on to hold the board. Other shops use flat springs of very thin steel bent up like trousers' guards that the bicycler uses. In fact, I have seen these very guards doing duty at the babbitt bench.

In pouring the box, the molten metal runs in through one of the holes, i, i, which are provided expressly for that purposes, and are left filled with babbitt when the job is done. The small ends, g, h, are to fit the bearings in the jig, as stated, and prevent both side and end motion of the mandrel, as the ends, one of which is seen at a fit snug between the bearings, a a, Fig. 11.

The "anvil," b, in this illustration, is bolted to the bearing piece, a a, and may be made interchangeable for different sizes of boxes, but experience has shown that better and truer boxes can be turned out when separate jigs are used for different sizes; there is less chance for the mandrel and box to get out of line when clamped in the jig, and as the hole must be parallel with the casting, in any finished box, it is necessary to allow every point that is in favor of this result.

Both the bearings, and the saddle, a, e, and b, Fig. 11, should be bored at the same operation, so as to be in line; and the anvil should be so locked and bolted to the bearing strap,

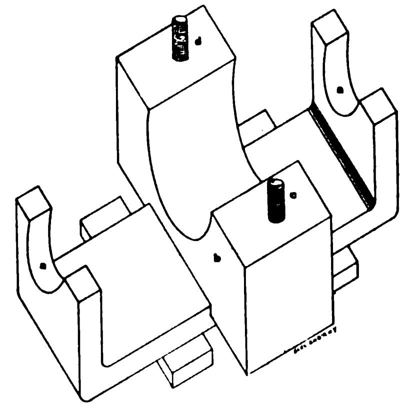

FIG. 11.—JIG FOR LINING SOLID BOXES.

that there will never be any movement between them. The accuracy of the finished box depends upon the correctness of the jigs, and they can profitably have considerable time spent on their making and care after being made and in use.

A common planer clamp, made of three-quarter inch square steel, is placed on top of the box after it is in position in the jig, and is held by screwing down the nuts on studs, c, d, making everything solid and ready for the babbitt. The pouring should be done quickly, a stream as big as will go through the hole, being run in. The mandrel and box must be warm, in order to secure a good bearing, and the metal just hot enough to flow well. The thinner the cavity or space into

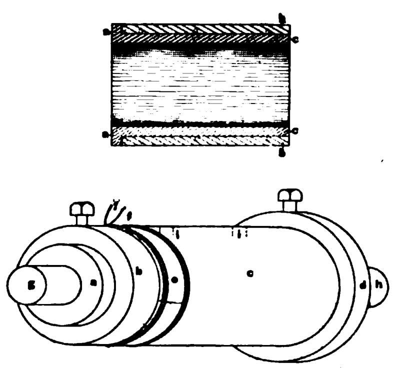
which the babbitt must run, the hotter it must be, and the greater the necessity for having the box well heated also.

More attention should be given to melting babbitt metal than is now paid that important part of the work. Often all the appliances consist of a cast iron kettle, or a pot, requisitioned from some restaurant or scrap heap, is the crucible in which the lining metal must be melted. This will do, but it is far from the best, or the most economical appliance.

Get a crucible made for the purpose, one that is large and deep, and into which there can be put a dozen boxes for the purpose of melting out the old babbitt metal. Take a few lessons from the type founder, and instead of having to dip out the hot metal with a ladle, have a spout arranged much like the flow-trough of an iron-founder's furnace; then with a valve arranged to work from the outside, the hot metal can be drawn off as desired without getting a lot of dirt from the top of the metal, and without the necessity of keeping the hot metal uncovered so it can oxidize itself into dross at a fast rate.

The pouring, as stated, should be done with a full stream, and as soon as the metal is in, the nuts should be taken off and the box removed from the jig to a driving-off stand. The great trouble with the casting of solid boxes is to get the mandrel out. This must be done before the metal has a chance to cool much, for the longer the mandrel stays in contact with the hot metal, the harder it will come out. The best way, then, is to remove the box as soon as possible and set it on a "driving-off stand," which is exactly similar to the usual rig for driving out mandrels. The usual copper or rawhide hammer is used, and the mandrel forced out.

A good deal of care should be given to melting out the old lining without heating the babbitt kettle too hot. There is a



FIGS. 12 AND 13.

fine opportunity for burning out the bottom of a kettle of this kind, and much care is necessary to prevent it. The melting out heat should never be greater than is barely necessary to start the babbitt, and if the iron is just hot enough to flash oil into flame, then the babbitt will come out and no harm be done to the castings. Indeed, I believe that a cast iron box is all the better for having been heated in this manner for several times, as the strains of casting are allowed to readjust themselves; it gives the castings a sort of annealing, and makes them tougher and less apt to fail under the strain of operation.

The usual method of cleaning a box after the old lining has been melted out, is to rub off some of the dirt with the stub of an old broom. There is a much better way than this: get a few scratch brushes and rub one of them over the box. It will take off all the dirt, slick and clean, and there will be no burning of the broom, and making a big smoke and stench. A small scratch brush that will go into the box, should be used for cleaning out the inside of the casting. A better lining is always the result when both box and mandrel are very clean.

Grease and oil will do no harm in a box when the babbitt is poured in, but beware of any water. The presence of moisture will always cause a poor surface to the metal in the lining, even if it does not spoil it, and there is always great danger of an explosion which will throw the hot metal many feet, when moisture comes in contact with melted lead or any other metal.

When the open pot must be used for both melting out and for filling boxes, nearly all of the waste of metal by oxidization and the trouble from dirt may be avoided by putting a ring into the metal to dip the ladle through. Just a piece of large stove pipe is all that is needed. When ready to pour a box, fan the dirt away with the pipe and push it right down into the hot metal.

The piece of iron need not be very long, four or five inches is enough, and after working it down through the dirt and dross, let it go and it will float in the hot babbitt, probably not quite one-fourth of the iron projecting above the babbitt. This is under the supposition that the iron has a specific gravity of about 7.7, and the babbitt metal averages 10. This would give about 77-100 of the iron under the babbitt, and 23-100, or a little less than one-quarter, as stated, to stick up above the top of the metal to keep the dirt away so the ladle can be dipped directly into the clean babbitt without having to stop to skim or to run the risk of pouring a bad box without skimming. Take the iron ring out when not pouring. A lot of the babbitt will oxidize in a short time when the clean bright surface of the hot metal is exposed directly to the atmosphere.

When trouble is met with in keeping the lining in boxes, especially when they are subjected to a good deal of jarring, the inside of the casting may be tinned before the lining metal is poured in, and, if the tinning is well done, and the babbitt metal pretty hot, it will join itself to the box so tight that it can only be got off by melting or chipping. Brass boxes in particular take kindly to this method, but iron boxes can be tinned by means of acid baths, by first picking in dilute sulphuric acid to remove the scale, then immersing in hydrochloric (muriatic) acid in which zinc has been dissolved. This gives the iron a thin coating of zinc, and if poured very hot—hot enough to melt lead, the babbitt will stick to the thin zinc coating.

It is better practice to go over the inside of the boxes, after dipping in the acid-zinc solution, with some melted lead and tin solder), and work a coating of it on over the zinc. This is easily done by keeping the box hot over a gas flame, or a charcoal fire, and working the melted solder around with a small scratch brush which is occasionally wet in the acid-zinc solution. As soon as tinned, the boxes should be put on the mandrel, in the jig, and poured while hot. There is no get-away to a lining put in thus. It is expensive, but pays for certain places.

TELEPHONY AND TELEGRAPHY

GLASS TELEPHONE CABINETS.

BESIDES the requirements of imperviousness to sound which telephone cabinets call for, there are others which a perfect structure of this kind requires. Among other things the matter of interior illumination is of importance, and frequently the absence of light is the cause of considerable inconvenience. The illumination must be such that reading and writing are easy. Even when good daylight is available large windows do not often permit of this, and it also happens even with artificial light, when placed outside of the booth to avoid excessive heat. It is also desirable in using these

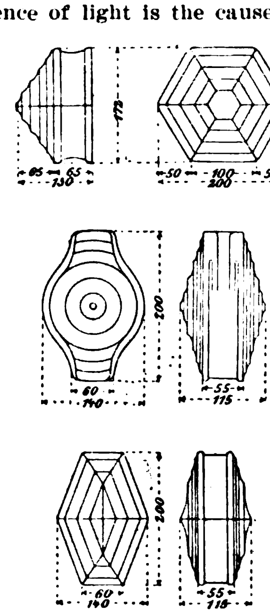


FIG. 1.

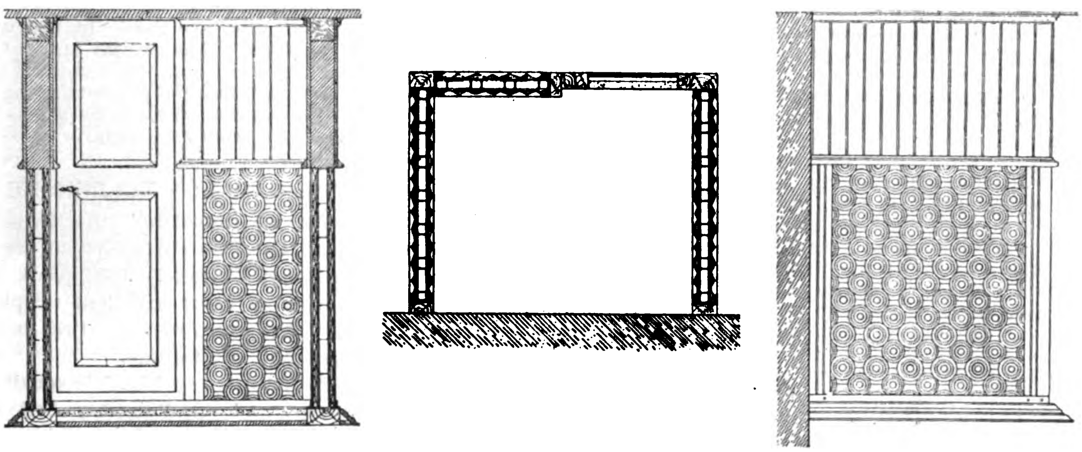
booths that the presence of a user telephoning should be noticeable from without the cabinet, yet that the features of the person within cannot be recognized, and especially that the memoranda made by the user of the telephone cannot be read from without. These conditions are but rarely satisfied with milk or ribbed glass. Large panes of glass seriously interfere with the sound-proof qualities of the booth, and have the disadvantage that in case of damage the repairs are quite expensive.

Most of the difficulties above enumerated, says the "Elektrotechnische Zeitschrift," are overcome by the Falconnier glass "building stones." These glass stones are hollow bodies, the interior of which is filled with compressed air. They are employed in hexagonal or fish bladder shapes, as shown in Fig. 1, and come from the glass works ready for use, and their application is quite simple. They are laid like ordinary bricks in mortar, consisting of 1-5 fine sand, 3-5 Portland and 1-5 Roman cement. The joints must be completely full, and can be pointed immediately after laying. Where the light is to be brought in from above, arches built up of these glass stones can be constructed in the same manner as is usually done in the case of bricks. Figs. 2, 3 and 4 show side elevation, vertical and horizontal section of the telephone booth, three sides of which are constructed of these glass stones. The latter rest upon a breast wall of bricks covered by an apron of boards. A frame of U and T-irons forms a skeleton for the glass walls and for the fastening of the wood framing of the door, etc., and also as a support for the roof.



FIGS. 2, 3 AND 4.—METHOD OF CONSTRUCTING GLASS SOUNDPROOF TELEPHONE CABINETS.

In locations where the temperature is low, and the variation in humidity not great, the frame could also be constructed of wood. The roof and the door are built up of wood and cork, with a layer of air between them. There is no difficulty, however, in constructing even the door of glass where the requirements of absolute sound-proofness demand it.

The cabinet illustrated has been in use for 1½ years, with good results, and the imperviousness to sound attained with it is said not to be attained with any other building material.

PRIVATE TELEPHONE CONSTRUCTION.—II.

BY F. H. SMITH.

IT is quite a common thing for a merchant in a town to have his home and store connected with his place of business by telephone. Such is true of the doctor between his home and office, also the lawyer, and some other business men and professional people.

In the smaller towns this is quite an easy matter, since the right of way for wires can be secured, but in the large towns and the cities this does not hold true. It is quite a common thing in the cities for persons to buy telephones and arrange with some linemen to put them up and string the necessary wire; but soon endless trouble with the circuits commences. The wires are found on buildings and are disconnected, also on the poles of the various electric companies, when they are cut down. Before buying instruments for a private line in a city it is a good plan to try and make arrangements for the circuit. Sometimes arrangements can be made with some one of the electric companies to have the wires strung on their poles and often arrangements can be made with the property owners to have the wires fastened to buildings, if they are to be put up in a proper manner.

When two or three places are to be connected with telephones where the wire can be strung permanently, as many complete telephones should be purchased with magneto bells for calling purposes. Two good open circuit batteries for each instrument, a sufficient quantity of No. 14 B. and S. iron or steel wire, the best grade, and the best lineman that can be procured should be employed to put up the wires. If poles have got to be set, get them heavy enough, so that when well tamped for four or five feet in the ground, they will stand straight. Find out from the local electric companies what timber makes the best pole, in the section where the work is to be done, cost and lasting qualities considered; have them at least four inches in diameter at the top and long enough so that the bracket, if one wire is to be strung, or the cross arm if two wires, shall be 18 feet above ground.

If the wire is what it should be and is not damaged in putting up, it should hold together during a bad sleet storm if the poles are 200 feet apart. The regular two-pin arm and pony glass will complete the outside equipment.

In the country where there are no gas and water pipes, especially if the soil gets very dry during some seasons of the year, two wires should be strung so as to have a metallic circuit. If a river runs parallel with the pole line, it may be used for a return by running a wire from one side of the

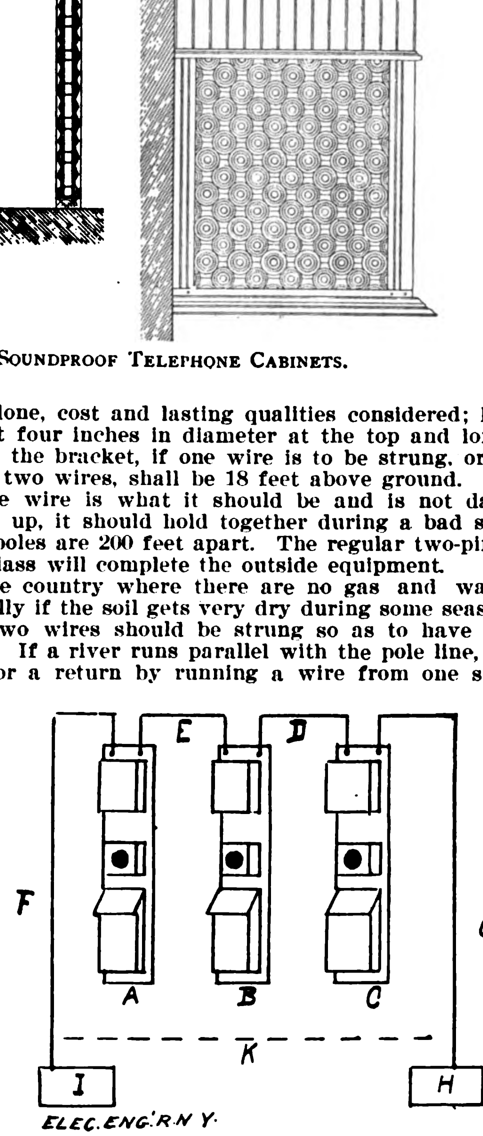


FIG. 1.

telephone to a small iron or copper plate on the bank and putting the plate where it will always be under water. In using plates in the ground they should be put deep down in wet or swampy places. Very much trouble has been had with private telephone lines when the ground has been used for a return.

Fig. 1 illustrates the arrangement of the instruments in this case. All three bells will always ring at once, and if the three ear pieces are down, a person speaking in any one transmitter can be heard in the other two. The principal objection is the system of ringing that is necessary. With only two telephones one ring is all that is necessary to call for either telephone, but with three it is essential to have an understanding that one ring calls a certain instrument, two rings another, and three rings the third phone.

We will consider A, B and C to be the three telephones connected by the line wire E and D; F and G the wires that are the ones leading to the water pipes, or ground plates H and I,

or back to the wire K, when no ground return is used.

Fig. 2 illustrates the warehouse system with no central station. We will consider that we are going to install five stations. • We will adopt the full length case with battery box large enough for two wet batteries in case we should want to use two, as the instruments are going to be some distance apart, and we want to use small copper in the circuits, and get a good sharp ring at calls; we will decide on telephones with magneto bells for calls. Young and old, short and tall are to use the instruments, so we are compelled to have adjustable arms.

The factory in which they are to be installed, we will suppose, has rapidly running machinery that will tend to shake the instruments, so we will try to get them all on the brick walls that enclose the place.

Some warehouse telephones are made with a small switchboard in them, which is operated with a plug; this plug has got to be placed by hand and makes a very good arrangement, when every person is well instructed in the use of the apparatus and will leave the plug in the proper place when through using the telephone, so that the station can be called when wanted. Employés can, to a greater or less extent be controlled, but in our case we will consider that persons from the outside are going to be around the factory at times and use the telephones, and we want the best service we can get, if it don't cost any more. We will adopt the round switch with five points and have a spring in the lever of the switch

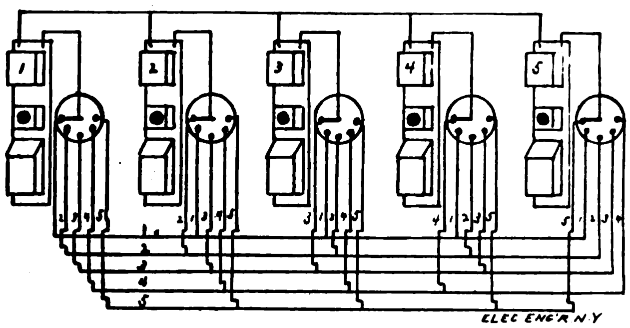

FIG. 2.

so that when the hand is taken from it the switch will return to the proper point for a call. It is very trying to undertake to get a remote place in the system and fail, simply because some person in a hurry has left the switch on the wrong point.

There is one disadvantage with having the switch so arranged that it is necessary to hold the hand upon it while speaking to a person at another station, and that is the fact that the switch has got to be put in some convenient position for the hand to be placed when the telephone is being spoken into. If placed right over the battery box, when made into the telephone case, it is all right for either a right or left handed person. When not built into the case it might be put right under the battery box on the wall, but in such a place it would be difficult to see.

The next best place would be just to the right of the top of the battery box. One of the first things that a person, who has a telephone that is not automatic in replacing the switch, will say is: "You cannot write while using the telephone if both hands have got to be used to operate the apparatus." This is true, and should be considered in deciding this question. It is quite an easy matter to take part of a message, write it down, and then take more and so on. This would be the writer's choice rather than have the apparatus so that it could not be used most of the time.

In our case we will not wed ourselves to any particular make of telephones, and so we will put our switch just to the right of the apparatus, as in Fig. 2. For five telephone stations we will use annunciator wire No. 18, B. and S. gauge with five colors or combinations of colors in the insulation. White and blue for the wire running directly to each instrument independent of the switch. Thus we will never be compelled to do any tracing but will know just the wire to use for the binding posts that are all connected to one straight wire. In this case they are on the left of the instrument. The right hand posts could just as well be used, but if one right hand post is used for this purpose, for the same purpose the right hand post of each instrument should be used to make the work symmetrical.

For No. 1 station switch wire we will use white and blue; for No. 2 white and red; for No. 3 red and blue; for No. 4 plain blue; for No. 5 plain red. On paper this looks very simple, but let a careless fellow, with but a faint idea of the task on hand, undertake this work with one or two colors of wire, and some great running, guessing, testing, changing and swearing are apt to be done before the job is complete, and the wire at places will be a hopeless snarl. A good man at the business could use one color of insulation and a few tags, where the work was concealed, and come out all right, but the average all-around wireman could not do it.

In some cases the battery in combination with a push, is used to work the call bells, but it is a question if this is economy in the end. Good magneto call bells are not expensive, and it is policy to always dispense with battery current, if possible, in such work.

If connections and taps are made in the wires, all such should be very carefully soldered and taped. In the engraving it looks as though it would be necessary to make many taps or many times add branch wires running to the various switches, but if the work is planned by a good man, in many cases the tap will be dispensed with.

THE STROMBERG-CARLSON TELEPHONE APPARATUS.

In a recent issue we illustrated the telephone exchange switchboard of the Stromberg-Carlson Telephone Manufacturing Company, of Chicago. This week we are enabled to describe a variety of other excellent telephone apparatus, manufactured by that company, relating more particularly to the subscriber's end of the line.

The transmitter illustrated in Fig. 1 is sensitive in its action yet not too delicate, and requires very little battery power. The diaphragm is not loaded or damped in any way, and its full vibration value is realized, while the double diaphragm renders the transmitter moisture-proof, and prevents buckling

FIG. 5.—STROMBERG-CARLSON CABINET SWITCHBOARD.

of the vibrating diaphragm by the heat and moisture of the breath. With this transmitter, and the Stromberg-Carlson receiver, conversations have been carried on with one of the parties standing at distance of 100 feet from the telephone. For mines and other damp places it is hermetically sealed, and made so watertight that it can be totally immersed in water without the entrance of moisture to pack or sicken the carbon grains.

The Stromberg-Carlson receiver is a specially loud speaking apparatus. This receiver can neither be tampered with nor thrown out of adjustment by variations of temperature. The special bi-polar magnets are capable of sustaining a dead weight of six and one-half pounds. All expansion of the magnets is away from the diaphragm end, the poles being firmly fixed to a solid brass head, so made that the distance from poles to diaphragm, when the receiver is once adjusted and locked, remains always the same.

There are no binding-posts for attaching the cord, and therefore no breakage or loose connections are possible. The

receiver is hermetically sealed, and excludes all moisture, dust, and other foreign substances.

Fig. 2 illustrates the type of long distance and wall exchange transmitter set. Between the usual magneto and battery boxes is placed a "triplet set," which is a self-contained arrangement of transmitter, receiver, switch and induction coil, compactly assembled. The extension arm is of the usual pattern, permitting adjustment to the heights of different individuals. Only two cells of battery are required up to any distance not exceeding 2,000 miles.

Fig. 1.

Fig. 4.

Fig. 2.

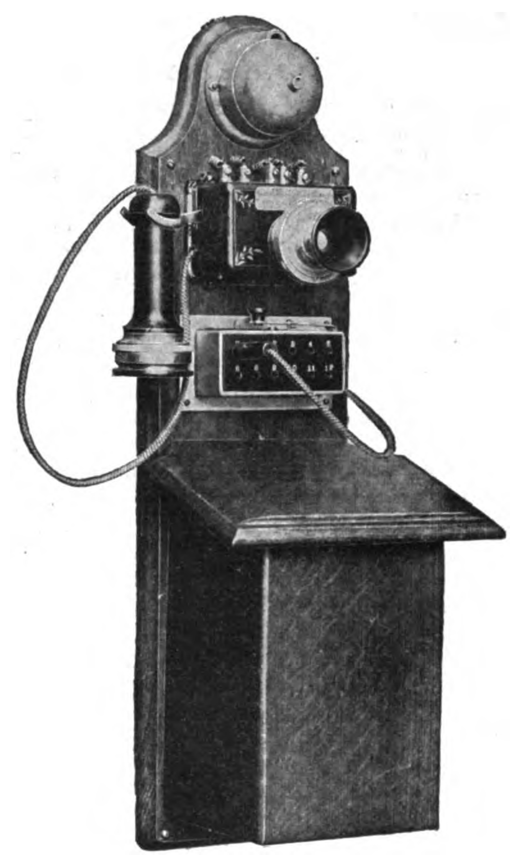

Fig. 3.

Stromberg-Carlson Telephone Apparatus.

To meet the demands of an intercommunicating system in houses, factories, offices, etc., the company have designed a complete local system, the transmitter of which is shown in Fig. 3. The local plug or switch is placed below the transmitter "triplet." An original and valuable feature of the system is, that it makes no difference whether the local plug be left in its proper jack or not; the station can always be called from any other station. The system is also arranged so that eavesdropping can be rendered impossible. Fig. 4 illustrates the desk set designed for the intercommunicating system.

Where the number of instruments is such that the plug board can not well be attached to the transmitter, the company build the cabinet switchboard shown in Fig. 5. These are made up in sets of less than 25 drops.

TO AVOID "BUSY" CALLS.

In order to expedite the use of the telephone on Saturday morning, and as much as possible avoid "busy" calls, the Chicago Telephone Company is advising its patrons to spread out the time of use on that morning so as to cover as many hours as possible, and for that purpose the following notice is being sent to the subscribers in the Chicago exchange:

Owing to the general observance of the Saturday half holiday and the consequent rush of business during the morning hours of that day subscribers will expedite their own calls and avoid "busy" calls to a greater extent by extending the period of use of their telephone over as large a number of hours as possible. A very great number of subscribers now attempt to do all of the morning's telephoning between the hours of 10 and 11. As a result, many unavailing calls are made for lines which are almost continuously busy during that hour. By beginning the morning's business which is accomplished by telephone at an earlier hour and extending it at a more even rate up to 12 o'clock, the service will be expedited. Subscribers whose telephones are of greatest value for receiving calls are recommended to keep their lines as free as possible for that purpose and to avoid blocking them by outgoing messages. Subscribers who have more than one trunk line or telephone are recommended to keep one line free for incoming work as much as possible.

STOCK TICKER QUOTATIONS IN NEW YORK.

The contract under which the Western Union Telegraph Company obtains the quotations which it distributes to the public over the tickers of its subsidiary company, the Gold and Stock Telegraph Company expired with the close of business on the Exchange June 30. It is not expected, however, that the quotation service will be cut off. The Committee of Arrangements of the Exchange has the power to continue to furnish the quotations from day to day to the Western Union Company without a new contract, and this is what Wall street generally expects will be done in case a new contract is not at once arranged. Any new contract is expected to be in terms that will prevent the quotations from going to the bucket shops.

It was announced at the office of the Western Union Telegraph Company that there would be no interruption of quotation service over the tickers because of the expiration of the contract. No details have ben given as to the terms or conditions under which the service will be continued.

VOL. XXIV. NEW YORK, JULY 15, 1897. No. 480.

MILLIONS IN IT FOR MORGAN.

IF one of the Sunday newspapers is to be believed—and we all know how thoroughly trustworthy some of them are—the only time that Mr. J. P. Morgan ever let his friends into a hole was when he got them to put money into General Electric. But, according to the New York "World" of July 11, he is going to rectify even that little blunder, and show that it was not a blunder by pulling off the biggest thing ever known in the booming of Wall Street industrials. Mr. Morgan's plan of campaign is based on two elements, viz., the third-rail system and the control of nine systems of steam railroad. Everybody knows what a howling success the third-rail method is, and in applying that to 27,367 miles of track, Mr. Morgan and his associates will make $136,000,000, a sum which is estimated altogether too low, as only 25 per cent. profit is allowed, when it is a notorious fact that the profit on electrical apparatus is nearer 75 per cent. However, we will let the "World" do its own cautious figuring, and here reproduce its own table of careful calculations:

HOW MORGAN MAKES MILLIONS.

His 27,367 Miles of Railroad Will Be Equipped with the General Electric Company's "Third Rail" System Which He Controls.

WHERE THE GAIN COMES IN.

Name of Railroad.	Mileage.	Cost of Third Rail Equipment.	Morgan's Profit.
New York Central	5,280	$105,600,000	$26,400,000
N. Y., N. H. & Hartford	2,023	40,460,000	10,115,000
Erie	3,727	74,540,000	18,635,000
Philadelphia & Reading	1,277	25,540,000	6,385,000
Lehigh Valley	2,694	53,880,000	13,470,000
Southern Railway	4,752	95,040,000	23,760,000
Northern Pacific	4,346	86,920,000	21,730,000
Cleve., Cin., Chi. & St. L.	2,435	48,700,000	12,175,000
Chesapeake & Ohio	843	16,860,000	4,215,000
Total	27,367	$547,540,000	$136,885,000

HOW IT WILL AFFECT STOCKS.

Authorized capital, General Electric Company	$50,000,000
Stock issued, common, par value	30,460,000
Stock issued, preferred, par value	2,260,000
Controlled by J. P. Morgan and friends, par value	25,000,000
Present market value, Morgan holdings, at 33 1-3	8,250,000
Probable future market value, General Electric, per share	300
Probable future value of Morgan holdings	75,000,000
Net gain in value of Morgan stocks	66,250,000

SUMMARY.

Mr. Morgan's profit as a manufacturer of electrical railway equipment	$136,885,000
Mr. Morgan's profit as holder of electrical stocks	66,250,000
Total profit	$203,135,000

In view of the fact that General Electric is to earn $136,000,000 and to go up to $300 per share, is it any wonder that it is already up to 33½, or 8 points higher than at this time last year?

GERMAN CENTRAL STATION STATISTICS.

OF all the European countries, Germany may be said to have from the very start taken up electric lighting in the most enterprising manner. While the extent to which electrical work has been carried out in Germany has in the past been but a small percentage of the development which has been accomplished in the United States, yet as compared with its neighbors, the Fatherland has left them well in the rear. That Germany has not ceased its efforts towards popularizing the electric light is plainly shown in the most recent statistics of German central stations, which we find tabulated in excellent detail in the current number of the Elektrotechnische Zeitschrift. These statistics, aside from their being a mere record of good work accomplished, afford a fairly good insight into the tendencies of electrical work in Germany.

The record which is brought down to the first of March proves conclusively that electric lighting is no longer regarded as a luxury in Germany, but has become a necessity even in that country of highly developed domestic economy. While during the year 1894 only 148 central stations were in operation in Germany, there are now no less than 276, while 82 are in course of construction, or will shortly be begun. Taking a glance at the types of stations in relation to the nature of the current, power, etc., employed, we find that the direct current still leads, being employed in 70 per cent. of the stations, representing 66 per cent. of the actual total generating capacity. By far the larger number of direct current stations, that is, 80 per cent., are provided with storage batteries, the batteries representing 31 per cent. of the generator capacity of these stations. Nothing further is wanted to indicate the hold which storage batteries have gained in Germany. But it appears that the direct current is hard pressed by its old competitor, for we note a very decided increase in alternating current stations. Thus the number of exclusively alternating stations has risen from 16 in 1895, to 26 at the present time, and the generator capacity of these stations has increased correspondingly from 4,396 to 11,269 kilowatts. That is to say, an increase of 250 per cent. in eighteen months. On the other hand the total capacity of the exclusively direct current stations increased in the same time only 54 per cent. This is certainly a remarkable showing for the alternating current. During the same time the polyphase current has also taken a decided upward turn. We find no fewer than 27 such stations with a generating capacity of 11,163 kilowatts. In these 27 stations, however, there are included 11 stations having a capacity of 3,478 kilowatts, in which, in addition to the polyphase, direct current is also generated, or in which multiphase current is transformed into direct current for distribution. The accompanying table will enable a comparison to be made between the different systems in Germany during the last few years.

As regards the nature of the motive power employed, Germany is naturally restricted to a large extent to the employment of steam. Among the stations enumerated steam is employed exclusively in 57 per cent. of the total number, which represents 84 per cent. of the total engine capacity of all stations; and 17 per cent. of the stations are run by water power, but their total generator capacity amounts to only 4,300 kilowatts; whence it follows that only very small stations of less than 100 kilowatts depend exclusively upon water power. In fact, among these stations there are only 10 above 100 kilowatt capacity, and one of 1,360 kilowatt. However, there are 49 other stations which are also driven by water power, but have in addition another motive power, such as steam or gas as a reserve, but even in this case the total capacity only amounts to 5,463 kilowatts, so that, after all, only small stations are included in this category. It would seem, therefore, that the Germans consider it worth their while to utilize even the smallest water powers, even if forced to install auxiliary plants as a reserve in case of low water. Indeed, the statistics show that 36 per cent. of all the stations are at least partly driven by water power.

We have heard so much about the employment of gas lately in central stations that it is of special interest to note that gas cuts a very small figure in German central stations. In fact, we find only six stations with a total of only 460 kilowatt capacity, which are driven exclusively by means of gas; and in a few cases gas motors are used as reserve power. But what will strike American central station operators most forcibly is the fact that of all the stations in Germany one-half are of less than 100 kilowatt capacity. This indicates in a most marked degree that small towns which do not possess gas works are beginning to distribute light electrically. Among

the other stations 92 have a total capacity of from 101 to 500 k. w.; 13 from 500 to 1,000 k. w.; 12 from 1,001 to 2,000 k. w., and only 9 a total capacity of over 2,000 k. w. This is an exceedingly interesting development, and seems to indicate that in Germany the small station cuts quite as big a figure in the industry as does the large one.

As regards individual stations, the largest one in Germany, as it has been for some time past, is that of the Berliner Electricitätswerke in the Mauerstrasse, Berlin, with a capacity of 5,486 kilowatts. This is followed by the two stations in Hamburg, 4,760 and 4,182 k. w., respectively. Then comes Leipzig, with 2,300; Stuttgart, with 2,130 k. w.; Dresden, 2,088 k. w.; Frankfurt a. M., with 2,080 k. w., and finally two other Berlin stations of 2,028 k. w. capacity each.

	1894.	1895.	1896-97.	Per cent. Increase 1897 over 1895.

Alternating and Direct Current.				
No. of stations....	3	2	3	50 .
Capacity in k. w...	175	115	607	427.9

The extraordinary increase in the capacity of the stations over the record of the preceding eighteen months indicates that the number of lamps and motors connected with the circuits is steadily on the increase, and also indicates that the fears sometimes expressed as to the effect of the Welsbach light on electric lighting are groundless. This is proved by a glance at the actual number of lamps connected, as illustrated in the accompanying table. Counting a 10-ampere arc lamp equal to 10 incandescent lamps, and 1 h. p. (German) in motors equal to 18 50-watt incandescent lamps, we arrive at a figure of 1,668,587 incandescent lamps, or 83,429 kilowatts, whereas the total capacity of all stations is 78,236 kilowatts. The above table will also show the enormous increase in the number of motors connected to the circuits during the last few years, which now amount to no less than 23½ per cent. of the total connected station capacity.

	No. of Stations.	50-Watt Inc. Lamps Connected.	10-Amp. Arc Lamps Connected.	Motors Connected H. P.
1894	148	493,081	12,357	5,635
1895	180	602,986	15,396	10,254
1896-97	265	1,025,785	25,024	21,809
Increase 1897 over 1895 in per cent..	47.2	70.1	62.5	112.7

All indications point to the fact that not only has Germany not reached the limit of its electrical development, but that, on the contrary, it has but fairly begun, and that a like increase may be looked forward to for several years to come. This is exceedingly encouraging from every point of view, especially keeping in sight the fact that the laws of Germany are very strict with regard to the formation and operation of private corporations operating under public franchises. These German statistics indicate that electric light can profitably be distributed under conditions which might be considered onerous in the United States. We venture to suggest that the excellent system of finance adopted, and, in fact, imposed, upon the stations in Germany has contributed much to this cheerful showing.

THE FUTURE ARC DYNAMO.

FOR a long time past one has heard so little of arc lighting machinery that one might almost be lulled into the belief that the art had become stationary. It is true that multiphase work has absorbed the best energies of electrical engineers during the last six or eight years, yet those who may have studied the situation a little closer will not fail to have noted distinct tendencies making themselves felt in arc lighting work. We do not here refer to the marvelous rise and progress in enclosed arc lighting which has led to the placing of over 30,000 enclosed arc lamps on circuits in the United States during the last three years; but we would rather call attention to the arc machine itself. The expensive operation of rows of thirty or forty lighters, which used to be the pride of arc stations of yore, was recognized in due time and led to the construction of larger units which have gradually assumed the proportions of 120 lighters and over, and we are given to understand that 300, and even 500 lighters, are on the tapis. But while concentration of power was recognized as a desirable end to strive for, it has also become apparent that this could be carried too far, and that some of the flexibility attainable with a larger number of smaller units was sacrificed. There are not many cities where circuits of 100 lamps or more can be operated to advantage, yet there are various situations in which 100 arc lamps are distributed on such classes of work that they are operated better on independent circuits. To enable arc machines of large capacity to fulfill this requisite has been the point kept in view in the latest constructions, one result of which is the most recent type of the Brush machine. A most interesting development in this new direction is the Rushmore machine, described on another page. In this machine the inventor claims to have solved the problem of leading out from a single machine a number of circuits entirely independent of one another, and hence individually regulable, an important advantage. While these developments are going on, one cannot help casting a glance toward the future of arc lighting. The enclosed arc lamp adapted for constant potential alternating circuits has given the arc light a firmer footing than it has ever enjoyed before. The continuous current arc machine will probably continue to hold its own for street lighting purposes for some time to come, but we note even now a tendency toward covering extended areas with alternating arc lamps, the ultimate outcome of which may make decided changes in arc lighting practice of the future.

DYNAMOS, MOTORS AND MACHINE SHOPS.

WITH regard to the views recently expressed at the Hartford meeting of the Mechanical Engineers, against the adoption of electric power in mills and factories, we find by inquiry that those ideas are far from being entertained by mechanical engineers in general. This was to be expected, for the members of the profession are highly intelligent, and have never yet failed to support any genuine advance in the arts. It may be pointed out as a proof of the real tendency in mechanics that while a large proportion of the work going through the engine, boiler, turbine and other machine shops is on electrical account, these shops are themselves not only liberal users of electricity, but are going into electrical work. More than one engine concern is building dynamos, not a few machine shops are turning out motors. But it is such steps as the recent consolidation of the Siemens-Halske Company and Pennsylvania Iron Works that are most significant of a process that has been going on for some years, and dates back at least to the time when Mr. Westinghouse began to give as much attention to electricity as he had theretofore paid to engines and air-brakes. The Walker Company, in Cleveland, is another large illustration of combining mechanical and electrical production, and it would not be stretching things to instance the growing Elwell-Parker Company as a case in which some of the best mechanical engineering talent in the country is deeply interested in manufacturing electrical apparatus on the grand scale. That more machinery shops of the first order will become largely, if not wholly, electrical in their output, we firmly believe.

ELECTRIC LIGHTING

THE RUSHMORE MULTICIRCUIT ARC MACHINE.

THE tendency of the past few years has been towards a steady increase in the capacity of arc light machines, so that whereas five or six years ago an 80-lighter was looked upon as a remarkable achievement, to-day 100 and 120-lighters are getting to be quite common, and machines of still greater capacity are promised. The tendency is also strong towards the designing of such large arc machines so that the output can be divided into independent circuits.

In line with this idea is a multicircuit arc dynamo recently constructed by Mr. S. W. Rushmore, of Jersey City, N. J., which is capable of supplying a number of independent circuits each automatically regulated from full load to short circuit, constituting as it were a true combination of a number of small machines with all the advantages that subdivision affords, but without its disadvantages.

The new machine is very simple in construction and has a large ring armature surrounded by a multipolar field. The field is somewhat different from the ordinary construction in that the magnet poles are not secured to a common field ring as in usual practice, but are arranged in pairs, each magnetically separated from the others. The armature and the poles are so proportioned that the section embraced by a

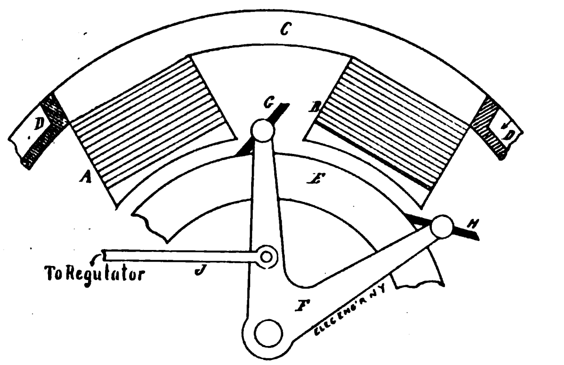

FIG. 1.

single pair of poles will have sufficient capacity to supply a circuit of arc lamps at the maximum voltage; and thus for each additional circuit the armature is made of greater size and there will be an additional magnet or pair of poles. In short, it is a number of arc machines incorporated in a single unit with an armature common to all.

In the first machine constructed on this plan some years ago, three brushes were employed for each section with one brush between the poles of each magnet and two brushes outside of the poles, the central brush forming one pole of the circuit and the outer brushes joined together to the other pole. This arrangement worked very well so long as the loads on the different sections remained the same, but when it was attempted to greatly vary the number of lights on one section, the brushes collecting currents for other circuits under other poles would flash badly and there was a great falling off in the capacity of the machine.

After studying the matter carefully, Mr. Rushmore concluded that this interference of the different sections was due to the current in the armature causing or allowing the flux from one section to flow to the other sections, and he concluded that the trouble would disappear if the armature flux due to the current in each circuit could be kept within its section, and he therefore arranged the machine with brushes to collect the current from the armature under but a single pole of each pair of magnets instead of under both poles. With this arrangement it was found that as much current could be collected from a section of the armature under a single pole as under both poles, while the idle pole served to keep the flux from flowing to the other sections; and no matter how much current was drawn from the armature under one section or separate magnet, there was no effect upon the other sections, and each section and pair of brushes would supply an independent circuit with varying current or pressure, entirely independent of all other sections.

In Fig. 1 is shown a section of the machine with a ring armature with poles A and B connected by yoke piece C; D, D are non-magnetic sections joining a magnet with other similar magnets to form a complete field; E is a section of the arma-

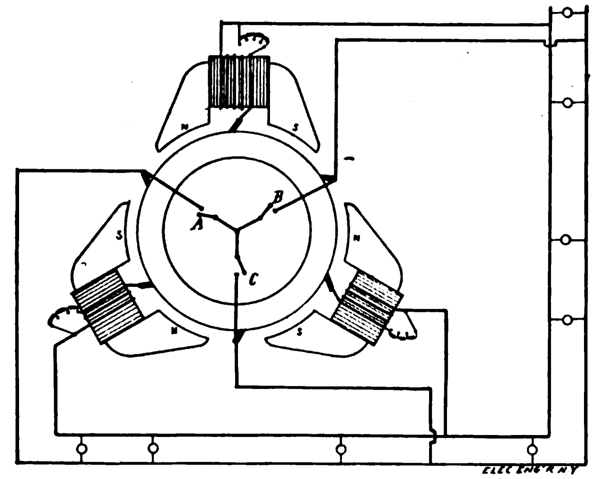

FIG. 2.

ture and F a brush rocker carrying brushes G and H, which are adapted to include between them the armature coils under pole B; J is a bar or lever connected to the regulator.

When the circuit supplied from the brushes is at its maximum voltage, the brushes will be shifted to a position with the pole, B, nearly central between them, and as lamps are cut out and less voltage is required, the regulator will shift the brushes toward pole A, thus distorting the field from pole B to keep down the voltage, as in bi-polar machines. As the current in the armature under pole A is only the small amount that will find its way around the armature from brush G to brush H, there will be little or no distortion of the field under pole A, and there will be no interference with the working of the other sections.

It has been found that machines constructed on this principle have very little tendency to flash and have such a wide inherent regulation that very little work is required of the regulator. The machine may be built with a large number of poles to supply a number of circuits and connected directly to the engine. In appearance it is practically the same as common types of multipolar machines, except that for each pair of poles there is a regulator to shift the brushes of that section.

This arrangement is not limited to arc machines, but may be applied to any service where it is desirable to have a single machine supply current at two or more different pressures, as applied to incandescent lighting and railway work. The machines may be built in large units to deliver the entire out-

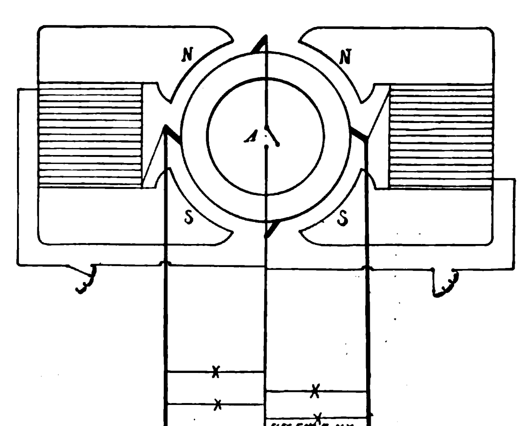

FIG. 3.

put at a single voltage, or at as many different voltages as there are pairs of poles surrounding the armature, as required. Thus, one or more sections of the machine may supply the main station buss, while other sections may supply feeders and be compounded to give any range of pressures required up to double the voltage of the main buss, thus dispensing

with boosters and special high pressure dynamos and improving the economy of the plant.

This is shown diagrammatically in Fig. 2, in which A, B and C are switches adapted to cross connect the brushes so that the current may be collected directly under a single pole of each section or under as many poles as conditions may require.

Fig. 3 shows the arrangement as applied to the three-wire system, in which case it is practically two independent machines connected in series and the load may be entirely removed from one side of the system without in any way affecting the other side, which may be fully loaded. In Fig. 3 A is a switch adapted to connect the brushes so that the current would be distributed equally throughout the armature, and this switch would be opened only when the system was so badly out of balance as to make it necessary to collect current under one pole as already described.

TEXT OF A PENNSYLVANIA BILL TO PROTECT LIGHTING PROPERTIES.

THE Simons bill, which compels municipal corporations in Pennsylvania to purchase the franchises and plants of existing electric light and gas companies before such municipalities can establish and operate plants of their own, is now in the hands of the Governor. It originated in the House and passed the Senate after being amended so as not to include water companies. The House concurred in the amendment, and the bill went to the Governor for his action.

The following is the full text of the act as it was sent to the Senate, which added a proviso exempting water companies from its operation:

An act supplementary to an act approved April 29, 1874, entitled "An act to provide for the incorporation and regulation of certain corporations," providing for the purchase of the franchises and property of certain corporations by the municipal corporation or corporations within the limits of which such franchises are exercised, and providing that such municipal corporation shall not itself undertake or perform any business or purposes of such corporation without first acquiring its franchises and property.

Section 1. Be it enacted, etc., that whenever rights, privileges or franchises have been or shall hereafter be granted by the Commonwealth to any corporation or corporations created under the act approved April 29, 1874, entitled "An act to provide for the incorporation and regulation of certain corporations," to which this is a supplement, or under any of the amendments or supplements to said act, and the exercise thereof by such corporations within the limits of any municipality or municipalities has been authorized or permitted by the municipal corporation or corporations by ordinances, contract, or otherwise, the municipal corporation or corporations within whose limits such rights, privileges, or franchises are exercised shall not itself undertake or perform any business or purpose of such corporations without first acquiring, in the manner hereafter prescribed, the rights, privileges and franchises granted to such corporation or corporations, and also the property of said corporations used in the exercise of said rights, privileges and franchises.

Section 2. That it shall be lawful at any time for any municipal corporation or corporations to become the owner of the works, property and franchises of any such corporation or corporations, by paying therefor such price as may be mutually agreed upon by and between such municipality and such corporation. If, in case of failure so to agree, such municipality or municipalities shall, notwithstanding such disagreement, provide by ordinance for the acquiring of the works, property and franchises of any such corporation, such municipality or municipalities shall thereupon present its petition to the Court of Common Pleas of the county in which such municipality or municipalities be located, asking for the appointment of viewers to assess the value of the works and property of such corporation in said municipality or municipalities, whereupon the court shall appoint seven discreet and disinterested freeholders of said county, and shall appoint a time for their meeting, of which meeting ten days' notice shall be given to all parties in interest; and the said viewers, having first been duly sworn or affirmed faithfully, justly and impartially to appraise said property and franchises, and having viewed the premises and taken such testimony as may be offered by either party touching the value of said property and franchise, shall estimate and determine the amount thereof, and make report of the same to the said court, which report having been confirmed by the said court, judgment shall be entered thereon by said court in favor of such corporation and against such municipality or municipalities. Each of said viewers shall be entitled to receive $2 for each day necessarily employed in the performance of the duties herein prescribed. Either party may, at any time within thirty days after the confirmation of such report, appeal therefrom to the said court. After such appeal, either party may put the cause at issue in the form directed by said court, and the same shall then be tried by said court and a jury, and, after final judgment, either party may have an appeal to the Supreme Court in the manner prescribed in other cases. The court shall have the power to order what notices shall be given in connection with any part of the proceedings, and may make all such orders connected with the same as may be deemed requisite. If any exceptions be filed with any appeal to the proceedings, they shall be speedily disposed of, and, if allowed, a new view shall be ordered, and, if disallowed, the appeal shall proceed as before provided; provided, that in estimating the value of all plants, franchises bestowed by municipalities shall not be considered a part of the plant.

Section 3. All laws or parts of laws inconsistent herewith are hereby repealed.

FIGHTING THE PROPOSED MUNICIPAL PLANT AT DES MOINES, IA.

A temporary injunction has been granted restraining the city of Des Moines from entering into a contract with the McCaskey-Holcomb Company for operating a lighting plant for the city, which should ultimately become the property of the city. It is claimed that the city may enter into debt to the extent only of $823,763, according to Iowa law, and that it now is and has been in debt to that amount, and hence that it has no power to incur further debt; that the bid was illegal because it was not founded on any bid made by the McCaskey-Holcomb Company in pursuance of a notice for bids; that the contract provides for public lighting for a period of two years, and that no such bid was asked for or received; that no appropriation was made for such a contract.

The election is said to be invalid and not to confer power to contract in this manner because no specimen ballots were prepared; no cards of instruction were prepared; the two propositions were contradictory and no citizen could vote for both at the same election; that 3,833 ballots were cast for both propositions and all such are illegal; that thirteen valid votes were cast in favor of the first proposition, and none for the second, and that 1,300 were cast against them.

ELECTRIC TRANSPORTATION

NIAGARA FALLS RAILWAY CONVENTION HALL.

AN illustration is shown herewith depicting the new convention hall at Niagara Falls, where the American Street Railway Association will meet next October. It was formerly the armory of the Forty-second Separate Company, and is situated on Walnut avenue, midway between the two busi-

EXHIBITION BUILDING, AMERICAN STREET RAILWAY ASSOCIATION, NIAGARA FALLS.

ness sections of the city. Its size when enlarged will be 132 feet by 132. The front is two stories high. On the upper floor is a hall for conventions seating from 200 to 300 people, and for larger gatherings the main auditorium is used. For

the purposes of the street railway meeting, all the space on the ground floor will be devoted to exhibits. The local street railway will run a branch to the hall for freight and passenger purposes; and a branch of the Erie road will also run to the building. The hotels are within ten minutes' distance.

THE FORD RAILWAY ELECTRIC TRAIN SIGNAL.

THE fact that a derailed pair of wheels, broken truck, broken car wheel, brake beam down, defective couplings, loads on flat cars shifting, and numerous other causes finally develop into expensive wrecks, which could easily be averted —provided the conductor could communicate instantly with the engineer, proves that a signalling device is required. The Ford railway electric train signal has been designed with this object in view.

It consists of a small three-wire cable properly insulated and

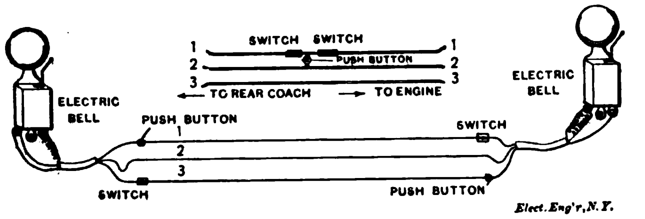

FIG. 1.—FORD'S RAILWAY ELECTRIC TRAIN SIGNAL.

attached to each car, both ends of this cable being provided with couplings which are very simple and work automatically in the event of a train breaking in two. After the cars have been switched together the couplings are made between each car and finally connected with an ordinary electric bell and dry battery in caboose and engine. By referring to Fig. 1, it will be seen that by a pressure on the push button in the caboose, a circuit is completed through wires Nos. 1 and 2; this rings the bell in engine and caboose, and by a pressure on the push button in the engine a circuit is completed through wires Nos. 3 and 2, thus ringing the bells in both engine and caboose.

This enables the conductor to communicate to the engineer instantly and accurately, in accordance with a code relative to break downs, etc. It also permits the engineer to communicate with the conductor and advise him of an anticipated stop, so that he may protect the rear end of his train, as well as make other communications regarding the condition of the

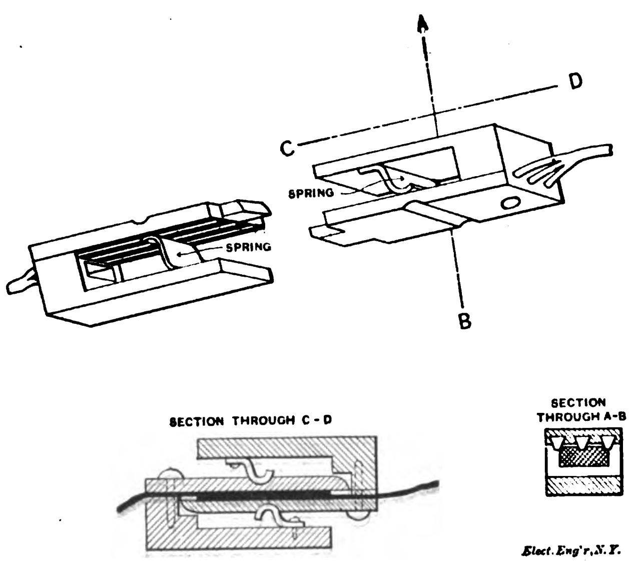

FIG. 2.—DETAILS OF FORD COUPLER.

cars near the engine, and at least save considerable time and avoid delaying trains.

In the event of a train breaking in two the wire coupling between the cars where the break occurs easily pulls apart, allowing the spring, shown in detail of coupler Fig. 2, to come in contact with the three wires, thus completing a circuit on the rear and through wires 2 and 3, which rings a bell in the caboose until the switch (shown on wire 3) is opened and circuit opened; and on the head end of the train the spring on the corresponding coupler comes in contact with wires and operates the same as on the rear end of the train, except that a circuit is completed through wires 1 and 2, which rings the bell in the engine until switch (wire No. 1) is turned and the circuit is thus opened. This enables both the engineer and conductor to know at once when a train parts, and they practically acknowledge receipt of this information by opening the electric switches to stop their bells ringing, and by adhering to the rules can prevent a collision of the detached parts.

The signal for passenger trains is exactly the same as for freight signal with the addition of a push button in each coach placed in the relative position to wires as shown in Fig. 2.

The one objection to this signal for freight train use will be that in the near future the law requiring all freight cars to be equipped with the "air brake" will be in effect. It is pointed out, however, that the practice of opening the air valve on the rear end of trains for the purpose of making an emergency stop, etc., is the prime cause of defective "draft rigging" and expensive repairs and delays to cars at terminal stations, and this can be avoided by use of a signal such as that described above.

BITTER STREET RAILWAY FIGHT IN ATLANTA, GA.

A special dispatch from Atlanta, Ga., of July 2 says: The contest between the city authorities and the Consolidated Street Railway Company, which has been in progress since the coming of the present administration took a sensational turn to-day, when it was learned that Mayor Collier will take steps to declare the company's charter void and the corporation illegal. The company, which controls nearly all the trolley lines in the city, is a combination of a number of car roads operated separately up to seven years ago, when the various corporations consolidated. Several months ago the city council passed an ordinance to compel the Consolidated to grant transfers.

The Old Colony Trust Company, of Boston, representing the bondholders, brought suit in the United States court to restrain the city from enforcing this ordinance. In an amendment which the city will make to its answer in that suit, the contention will be made that, having violated the provisions of the State constitution against the combination of competing railway lines, the Consolidated company's charter is null and void and the corporation an illegal one, without standing in court. The capital of the Consolidated is about $2,300,000, making the amount involved $4,300,000.

NEW STREET RAILWAY LAW IN MASSACHUSETTS.

A new law has gone into effect in Massachusetts, whereby the electric street railways come under the oversight of the State Board of Railroad Commissioners as they never have before. Heretofore, the railroad commissioners have had under their jurisdiction inspectors whose duty it has been to inspect the roadbeds, tracks, stations and rolling stock of the steam roads and also to investigate serious accidents upon the steam roads. Under the new law, which takes effect today, the inspectors are required to extend their examinations to the street railway lines as well, and in case any of the equipments of these lines are found not to be in compliance with the law, or in such a condition as to endanger the safety of the public or of the employés, the inspectors are to report in writing to the commissioners, who are empowered to take action. The inspectors are also required hereafter to investigate as promptly as possible any accident upon a street railway, attended by loss or risk of life, and to attend the inquests into deaths resulting from such accidents, and report the results of such investigations to the commissioners.

The State has been divided into districts and the several railroad inspectors assigned to different sections. The officials of the local street railways have received notice of the new law and its effects, from the railroad commissioners, but they do not regard it as of any great importance, as they consider that the inspections are likely to be of a more or less superficial nature and not of any particular value to the roads or to the public. The officials of the roads will cheerfully render the inspector any assistance possible in the performance of his new duties.

MONEY FOR NEW EQUIPMENT OF METROPOLITAN RAILROAD, NEW YORK.

The bonds issued by the Metropolitan Street Railway Company to raise the money for the equipment with the underground trolley of the lines on which that system will be used, are to be offered for public subscription this week. The issue is of $12,500,000 general mortgage 5 per cent. fifty-year gold bonds, secured by a lien on all of the company's property. The whole issue has been underwritten by a syndicate, and

only about $2,500,000 are said to be unsold. It is said that the bonds will be offered at 105 and interest.

THE POWER PLANT OF THE PIONEER ELECTRIC POWER COMPANY OF OGDEN, UTAH.

IN the canon of the Ogden River, near the city of Ogden, Utah, the latest and most important hydraulic power plant of that State, and one of the largest works of the kind yet undertaken in this country has been carried out during the past year by the Pioneer Electric Power Company of Utah. The city of Ogden is situated in the basin of the Great Salt Lake, at an elevation of 4,300 feet above sea level about 13 miles east of that body of water, and 35 miles north of Salt Lake City. The city extends eastward to the base of the Wahsatch Mountains, which tower 5,000 feet higher, reaching a total altitude of fully 9,000 feet above sea level. This chain of mountains is intersected by numerous deep valleys or canons, forming the outlet for drainage areas of considerable extent. The outlet of the narrow canon of the Ogden River is east of Ogden and distant about two miles from the business center. At a point about six miles above its mouth the gorge widens out into a valley, some eight miles long and four miles wide, surrounded by an almost continuous mountain chain. This valley is traversed by three streams which unite at the upper end of the canon to form the Ogden River.

The average annual rainfall in Ogden is 14 inches. In the Ogden Valley it is probably twice as great. The drainage area is about 360 square miles. The flow of the river varies greatly in different years and at different seasons. In May and June, when the snow on the mountains melts, a maximum flow of 4,800 cubic feet per second has been measured, while a minimum of 80 cubic feet in August and September is also on record. The minimum in average years is fully 125 cubic feet per second. The slope of the stream in the upper valley is comparatively gradual, while in the six miles of the canon there is a total fall of nearly 500 feet. This portion of the river has long appeared an attractive field for the development of power, but apart from a small saw-mill near its mouth

FIG. 1.—THE PIPE LINE ALONG THE SIDE OF THE CANYON.

there have been only abortive attempts made at utilizing the fall of the stream.

The plans of the Pioneer Electric Power Company contemplate the utilization of the waters of the entire Ogden River water shed above the mouth of the canon for the development of power as well as for irrigation. The central features of the plant are: A large storage reservoir and a masonry dam at the upper end of the canon; a pipe conduit 6 feet in diameter; a power house with water wheels and electric generators, electric transmission lines and substations for distributing the power to different points, and an extended system of irrigation canals.

The storage reservoir will cover an area of about 2,000 acres, and will have a capacity of nearly 15,000,000,000 gal-

FIG. 2.—EXTERIOR OF POWER HOUSE, SHOWING ONE VENTURI METER AND RECEIVER.

lons. It is formed by building across the canon, a short distance below its upper end, a dam of concrete masonry built up of isolated piers and arches founded on bed rock. The length of the dam on its crest is about 400 feet. It will have a total height of 100 feet, 60 feet of which will be above the level of the present river bed. The up-stream face is protected by a steel plate covering to prevent abrasion and percolation.

A 9-foot tunnel excavated through the solid rock around the south abutment of the dam forms the outlet for the water of the reservoir. At its upper end it connects to a masonry inlet tower, which is in turn connected by a riveted steel pipe 8 feet 6 inches in diameter with the main gate house, 100 feet below the tunnel. This contains two 72-inch valves, one controlling the supply of the main conduit, the other discharging the surplus water.

The main conduit is a pipe line 6 feet in internal diameter. Its total length is 31,600 feet, of which 27,000 feet is wooden stave pipe, and 4,600 feet at the lower end rivetted steel pipe. It is laid in a trench 8½ feet wide, and covered with earth to a depth of 3 feet on top. The selection of smooth wooden stave pipe in lieu of steel pipe throughout, was made on account of the greater cheapness of the former, as well as its less internal resistance to the flow. The pipe is laid along the side of the canon and follows the mountains to a point about half a mile beyond the mouth of the canon. It is built to conform to a hydraulic grade line of 2 feet per thousand, a slope believed to correspond to the friction in the pipe. At the upper end of the pipe the inlet is funnel shaped, and the wooden pipe is continuous except at three points where two rivetted steel elbows and a short length of tunnel are substituted. There are eight tunnels in the rock, the longest being 667 feet. There are also eight steel bridges with a total length of 560 feet besides a timber trestle. The maximum hydrostatic head in the wooden pipe is 117 feet, giving a pressure of 50 pounds per square inch.

From the end of the wooden pipe the steel conduit runs to the power house. The slope of this is quite steep and the

pressure is from 50 to 200 pounds per square inch. It is 60 feet in diameter until it reaches a point 100 feet from the power house, where it divides into two branches, 54 inches in diameter, which lead to two receivers, one on each side of the power house. There are 13 elbows in this pipe, and its entire weight is over 2,500,000 pounds. The total efficient head from the flow line of the reservoir when it is full to the center of the reservoir is 446 feet.

Between the inlet tower at the dam and the power house there are five large gate valves, besides the smaller blow-off and relief valves. Three are 6 feet in diameter, the other two 42 inches. The first two of the larger ones weigh about 23,000 pounds each and are in the gate house; the third is placed near elbow No. 2 of the steel pipe line about 100 feet below its junction with the wooden pipe. Its purpose is to permit the closing of the wooden pipe to keep it full of water even when the steel pipe is empty. The head at this point is about 200 feet. The valve has only a single valve stem and is operated by a hydraulic lift supplied with pressure water from the main pipe above the valve. The total weight of this valve is 52,000 pounds, the heaviest single piece in it weighing about 20,000 pounds. Besides these large valves there are two smaller, each 24 inches in diameter. These are placed between the lower end of the 6-foot pipe and the power house in the 54-inch branches leading to the receivers. These branches are reduced to 42 inches by the use of Venturi meters, thus permitting the use of the smaller valves, which are operated by hand. The pipe is fully provided with air, mud and relief valves. The connection between the main pipe and the branches is made by a breeches casting secured to the steel pipes by cast steel angle flanges and bolts. To withstand the great longitudinal pressure, a heavy concrete block is built around the casting. Of the nine bridges the longest is that over the Ogden River. This is a rivetted bow string girder 75 feet long. The other bridges carry the pipe line over lateral ravines or were built in place of masonry retaining walls, where a steel structure was cheaper.

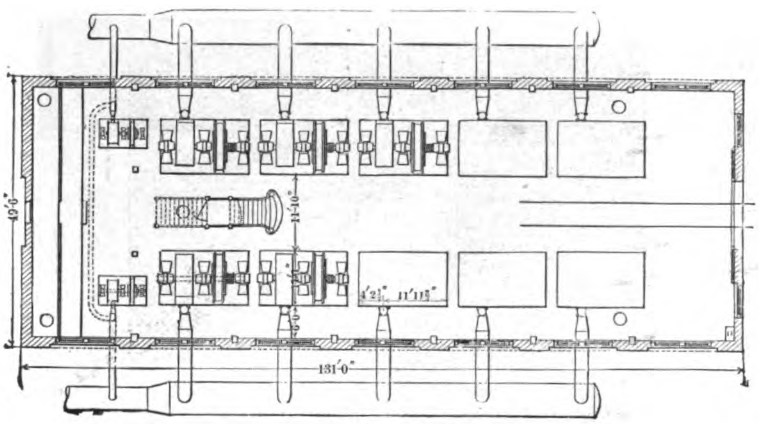

Fig. 3.—Plan of Power House.

The power house is built of pressed brick, with concrete and rubble footings, and cut stone trimmings. Its outside dimensions are 135 feet in length by 50 feet in width. The roof trusses are of steel, and are supported on steel posts imbedded in the brick walls. A traveling crane of 15 tons capacity, operated by hand power, traverses the building, the track girders being carried by the steel posts. This building contains all the hydraulic and electric machinery used. A smaller, separate building serves as a machine and blacksmith shop.

The water is delivered from the pipe conduit into two receivers, buried in the ground, one at either side of the power house. They are 6 feet in diameter and, in their general appearance and the material used, closely resemble the regular steel pipe conduit, the thickness of the metal, however, being increased to ⅞ inch in order to allow for the water hammer.

The receivers are provided with five safety valves each, which discharge when the pressure exceeds 200 pounds per square inch, and an outlet gate at the bottom. From each of these receivers, five 30-inch and one 10-inch, intake pipes extend to the walls of the power house to connect with the water wheel nozzle pipes. Between these intakes and the nozzle pipes are placed the following valves in the order named: One 18-inch geared gate valve, one 18-inch hydraulic gate valve and one 18-inch butterfly valve.

The 18-inch geared gate valve is only to be used in case of repairs to the particular machines that govern it. The 18-inch hydraulic gate valve is piped up to a small D valve, which is placed back of the switchboard and under the floor. By means of a lever on the switchboard, connected to this D valve, the gate can be opened or closed at the operator's will. This valve is the one which is to be used for starting or stopping a wheel. The 18-inch butterfly valve is operated by means of a worm gear from the governor, and is used in checking the speed of the wheel by reducing the head or pressure near the nozzle and thus avoiding a sudden fall of head in the main pipe which would be detrimental to the proper working of the plant.

The nozzle for the water wheels has six rectangular openings or ports 1 11-16 x 3½ inches in area, of which the operator is able to close one or more as he may desire. The levers that operate the hydraulic gate and nozzle are placed near the top of the switchboard. The set of levers for each water wheel is placed in the panel governing the generator which is driven by the wheel in question, so that the operations required in starting or stopping these machines are reduced to a minimum. The wheels are of the impulse type directly connected to the generators. The complete plant will consist of ten units, five being already installed. The power house and receivers being built for the ten, the balance can be readily installed at any time.

The Knight water wheels are 59 inches in diameter and have 45 bronze buckets cast in one solid piece; 14 of these will, when the nozzle ports are all open, receive the water at the same instant. The centers of the wheels are made of cast steel, the buckets being pressed on these steel centers and secured with bolts. These wheels are keyed to the generator shaft. Each wheel has a capacity of 1,200 horse-power at 300 revolutions per minute, and each is provided with two flywheels, about 70 inches in diameter, each weighing about two tons.

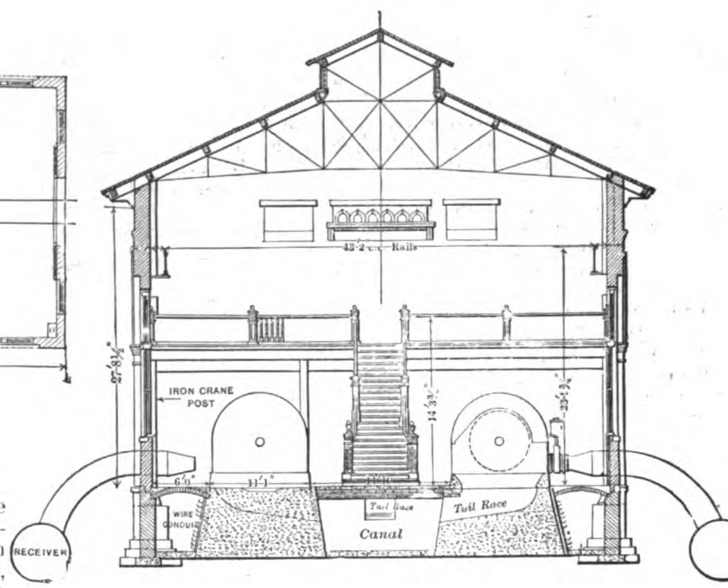

Fig. 4.—Section of Power House.

The armature, armature shaft, two fly-wheels and one water wheel, which comprise the moving parts, weigh 15 tons. This allows a uniform speed to be maintained notwithstanding changes of head in the main pipe, or changes in the generator load. The water wheel, fly wheels, nozzle and the two hydraulic cylinders controlling the nozzle ports are encased in a steel housing, bolted to the machine bed frame.

Between the two lines of machines and down through the center of the building underneath the concrete floor is the spillway into which the wheels discharge the water, and through which the water is carried back to the river from which it is taken.

The generators used in this plant are of the General Electric Company three-phase type, with 24 poles, and at 300 revolutions per minute, have an output of 750 kilowatt at 2,300 volts, and a frequency of 60 cycles per second. The factory tests show that the variation in volts will be less than 5 per cent. with a constant speed, should the full non-inductive load be thrown off or on.

Between the machine foundations and the building foundation wall, on each side of the building, is a subway which runs the entire length of the building and across the rear, and in this subway are carried all the necessary piping for water wheel controllers and all the wires between the generators and the switchboards. The cable connecting each

generator to its respective panel on the generator switchboard is a three-wire concentric 250,000 C. M. lead-covered cable, and the exciting wires are a two-wire concentric No. 4 B and S lead-covered cable.

The exciters used on this plant are G. E. six-pole 500 volt machines, and will give 100 kilowatt at 550 revolutions per minute. Each of these machines is ample for the entire exciting current that will be needed for the ten 750 kilowatt alternators, and they are each direct connected to a 135 horse-power Knight water wheel, similar to the 1,200 horse-power water wheels previously described. These exciter water wheels are cross-connected to each receiver, so that either exciter can be operated from either receiver.

The generator switchboard consists of seven marble panels; five for the alternators, one for the exciter and one for the instrument panel.

These panels are 26 x 90 inches each. They are built up of blue Vermont marble, with nickel fittings. There are two sets of three-phase bus bars on the back extending the entire length of the seven panels, as well as two bus bars, also running their entire length, from which the exciting current is taken.

From the generator switchboard the current is carried to the distributing board over copper bars, of which there are two sets of three, connecting the two sets of bus bars on the generator board with the two sets of bus bars on the primary panels of the distributing boards.

The distributing board is in a gallery in the rear of the building and over the generator switchboard. Back of this distributing switchboard are nine 250 kilowatt air blast step-up transformers, the lightning arresters, and the two blowers for cooling the transformers. The distributing board is divided into two sections—the primary section and the secondary section.

Back of the distributing switchboard and on a raised platform are placed the step-up transformers. These transformers raise the potential of the current from 2,300 to 16,100 volts, at which pressure it goes on to the long distance transmission lines. The transformers are connected up in sets of three, the delta connection being used on both sides. At each end of the building in the gallery are placed the two blowers, direct connected to a 2½ horse-power 500 volt direct current motor. These blowers are used in cooling the step-up transformers, and force the air up through the bottom of the transformers, around the coils and out at the top.

The transmission line is calculated to deliver about 3,000 horse-power at the sub-station in Salt Lake City, distant about 38 miles, and consists of two circuits, making six wires of No. 1 B and S gauge.

The poles used on this line are of Oregon cedar, and are good, clear, straight poles, 30, 40, 50 and 70 feet long, with 9-inch and 10-inch tops. There are two cross arms on each pole for the wire; two wires are on the top arm 4 feet apart, and four wires on the bottom arm, each 2 feet apart, a circuit being on each side of the pole. These wires are so arranged that should a plane be placed perpendicularly across the circuit it would show an equilateral triangle, with a wire at each angle, the length of the sides being 2 feet. These wires are transposed about every half mile. By this arrangement of the pole line wire, the inductive effect is reduced to a minimum.

About 6 feet below the second cross arm on the pole is a two-pin cross arm, on which the telephone wires are strung, being transposed about every four poles, there being an average of about 50 poles per mile.

The current is fed into the transmission line at the power plant at 16,100 volts and delivered to the step-down transformers at 13,800 volts. This will give an energy loss of about 10 per cent. in the line, and a potential loss of about 14 per cent. The substation step-down transformers deliver this current to the local distributing lines again at 2,300 volts. There are at present nine 250 kilowatt step-down transformers at the substation connected by the step-up transformers, and the switchboard in the substation is similar in every respect to the distributing board in the power plant gallery. The cooling apparatus here is also identical with that used in the power plant, except that the motors used are 60 cycle induction motors.

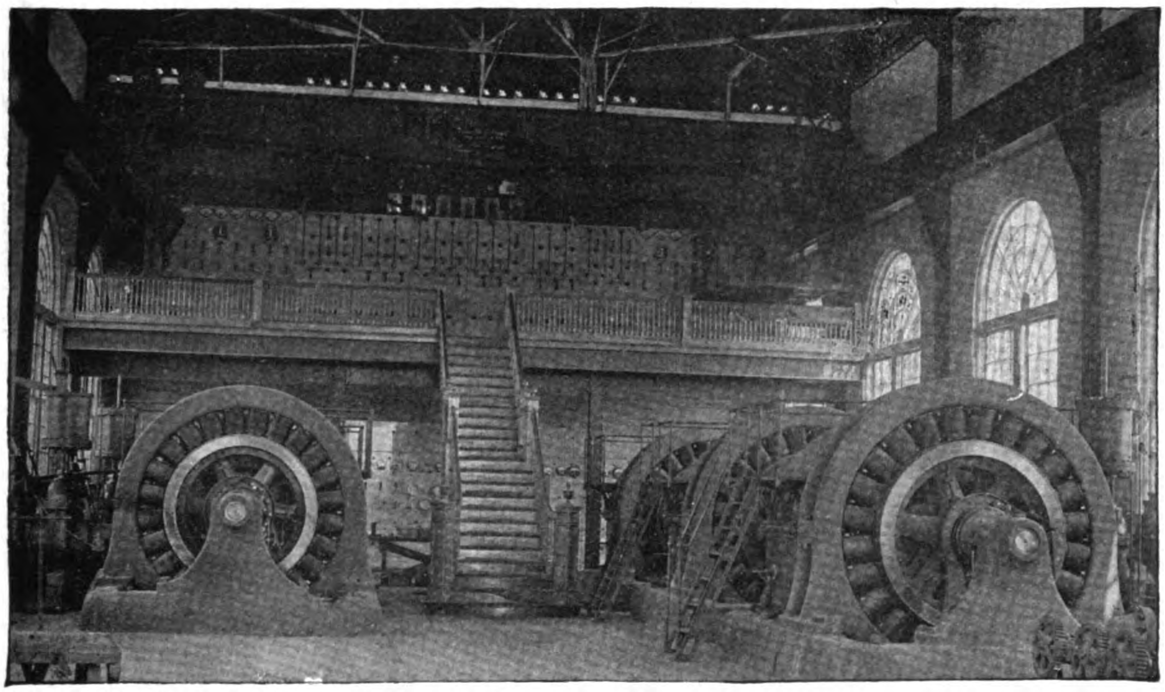

FIG. 5.—INTERIOR OF POWER HOUSE.

While the transmission lines are at present capable of delivering 3,000 horse-power at the substation, with a 10 per cent. energy loss, if it should become necessary, the step-up transformers can deliver more than this by changing three wires on their high pressure side, and delivering the current into the transmission lines at 27,000 volts. Thus the line capacity would be more than doubled.

The present installation of the power plant is capable of delivering 3,750 kilowatt to its lines, but ample provision has been made to increase this amount to 7,500 kilowatt by installing five more 750 kilowatt machines, as new industries or manufacturers spring up as the rsult of the advantages offered to them in Ogden and Salt Lake City.

There is one important feature in the arrangement of the machinery which should be noticed, viz., the complete duplication of all parts. All portions of the plant below the breeches pipe casting, at the lower end of the 6-foot conduit, are absolutely symmetrical about the center line of the power house, each side being entirely independent of the other. This applies not only to the pipe and the receivers, but to all the parts of the switchboards, etc., as well as to the generators and water wheels. Either one of the exciters, also, is capable of providing sufficient current for all the large generators, and can be run with water from either receiver. The advantage of this arrangement is that an accident to either receiver, or to one or more wheels or generators, would not result in the shutting down of the entire plant, but at the

worst of only one side. For a short period all the required power could probably be supplied from one side of the power house.

The current will be used to drive factories, running electric railways from Ogden to Salt Lake City, to the Lake, to Hot Springs and to light the towns and cities in the north of the State. The surplus water in the storage reservoir will be utilized to irrigate large tracts of land in the vicinity.

The Pioneer Electric Company was organized November 27, 1893. The president and treasurer of the company is the Hon. Geo. Q. Cannon, the head of the Mormon Church. The general manager is Frank J. Cannon, son of the president and United States Senator from the State of Utah. The directorate consists of W. Woodruff, president of the Mormon Church, Joseph F. Smith, one of his counselors, F. D. Richards, one of the apostles, Asahel Woodruff and A. B. Patton, president of the Ogden Chamber of Commerce; Mr. Patton and the chief engineer and secretary, Mr. C. K. Bannister, are the only men among the directorate not members of the Mormon Church.

The conception and successful completion of the works belonging to the Pioneer Electric Power Co. are largely due to the efforts of C. K. Bannister, C. E., who, as chief engineer and secretary of the company, has devoted several years to the careful study of the engineering and financial problems involved.

MECHANICAL

THE WORTHINGTON TWIN CYLINDER VERTICAL CONDENSER.

THE new special catalogue just issued by Henry R. Worthington contains descriptions of that well known firm's three types of condensers, among them the twin cylinder vertical condenser shown in the accompanying engraving. This is the result of the demand for an air pump and condenser to occupy the least possible floor space, and still have all its internal parts easily accessible, that has led to the design and construction of the Worthington twin cylinder vertical condenser, which represents the latest advancement that has been made in this class of apparatus. The accompanying engraving shows the pump with the condensing chamber removed. This chamber is usually placed at the rear and connects directly with the channel plate at the bottom of the pump. The opening in front is for the discharge water.

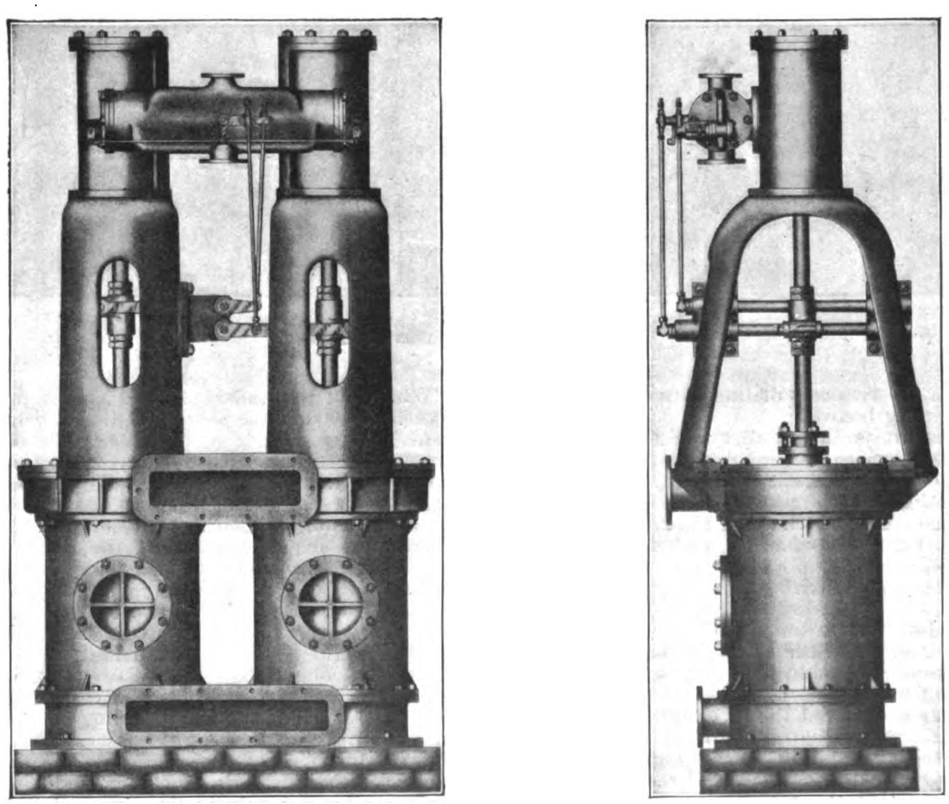
Each side of the pump is, of course, single-acting, the buckets being of the form used for years in attached air pumps on both marine and stationary engines. As one side goes down and does but practically little work, it is important that the other side should make an up-stroke at the same time and do full work in evacuating the condenser to which the suction of the pump is attached. The valve motion applied to the Worthington twin cylinder vertical air pump and condenser has the novel and valuable function of giving to the buckets the same constancy of action as would be obtained if they were rigidly connected by a beam, but with the advantage of an entire absence of side thrust such as is caused when a beam passes its center. The power of the steam pistons is transmitted directly through the piston rods to the air pump buckets, thus doing away with the beam, etc. There are thus no links, sliding cross-heads, gibs, keys nor journals to adjust, and an important saving in weight is accomplished.

The stroke of this pump is positively determined by the valve motion and neither bucket can begin a return stroke until the other bucket has entirely completed its stroke.

A feature of still greater importance is found in the fact that each air pump bucket pauses at the end of the downstroke and allows its bucket valves to close before the upstroke begins. The other bucket, however, during this pause, is still traveling upward and doing full work, so that there is no remission of effectiveness from this action.

The condensing chamber being attached to the channel plate or base of the air pump permits a reduction in the vertical distance from the foundation or floor line to injection opening, which is a substantial benefit in locations where it becomes necessary to place the condenser at an elevation considerably above the level of the water in the well. In such cases the adoption of this form of condenser materially reduces the total suction lift without necessitating changes or alterations in the plant.

On the other hand, it is frequently desired to place the condensing apparatus in a pit, and the Worthington vertical twin cylinder condenser is particularly well adapted to such locations; since the throttle, injection and regulating valves are all placed above, the condenser can be conveniently operated from the engine room floor. The most satisfactory and



WORTHINGTON TWIN CYLINDER VERTICAL CONDENSER.

gratifying results have been obtained with this form of condenser.

GAS FOR POWER PURPOSES.[1]

BY JOSEPH EMERSON DOWSON, M. Inst. C.E.

GAS engines driven with ordinary town gas offer the following advantages compared with steam engines: No ground space for a boiler is required, and no chimney; there is no boiler to clean and repair, and no boiler insurance; there are no clinkers and ashes to remove and no fireman to pay; the gas engine can be stopped or started at will, and there is no loss of fuel during the stand-by hours. Besides all this, there is the important fact that there is always a large storage of power to fall back on in the gasholders at the gas works. For intermittent work, such as hoisting, printing, etc., and for moderate powers working constantly, gas engines driven by gas taken from the town mains have such manifest advantages that to a large extent they have superseded steam engines, and will doubtless continue to do so. Almost the only drawback to the use of town gas is its cost, but in some places the day pressure in the mains is too low and gives trouble. It is generally admitted that when town gas costs more than 3s. per 1,000 cubic feet, the working cost of an engine indicating more than about 30 h. p. exceeds that of a steam engine of the same power, under the usual conditions of regular working.

For larger powers it is now usual to work a gas generating plant in connection with the engine, or there may be several engines served by one gas plant. In such cases the gas plant is to the gas engine what the boiler is to the steam engine. Approximately it occupies about the same ground space as a steam boiler of the same horse-power, and the fireman is of the same type in each case. With the gas plant there is no need of a chimney stack; but in towns or where there are adjoining houses it is desirable to have a small waste pipe from the generator carried up above the level of the roofs, so that when the fire in the generator is blown up after standing, the gases then formed may be blown off without nuisance. The repairs of a gas plant usually cost much less than the cleaning and repairs of a boiler for the same power. The first engine driven with generator gas was in 1879, and since then the adoption of this system of power has spread so rapidly in all countries that it is now quite impossible to estimate the numbers in use. The general outcome is that engines of good make (indicating 50 h. p. and upward), driven by generator gas of average quality, consume about 1 lb. of fuel, whereas good steam engines require 2 lb. to 3 lb. per i. h. p. hour.

An engine indicating about 120 h. p. has been run on test for five hours, with an actual fuel consumption of only ¾ lb. per i. h. p. On another occasion, with an engine indicating under 33 h. p., the gas plant was placed on a weighing machine, so as to obtain a series of actual records of the weight of fuel converted into power, and even on this small scale of working the fuel consumed was only 1.2 lb. per i. h. p. hour.

MARRIED

MILLER-KNOWLTON.

The wedding of Miss Antha Knowlton, daughter of Mrs. Knowlton, to Kempster Blanchard Miller, took place on Saturday, July 3, at 1807 Wesley avenue, Evanston, Ill., the residence of Mr. James E. Keelyn, president of the Western Telephone Construction Company, of Chicago. The Rev. Dr. Henson, of the First Baptist Church of Chicago, performed the ceremony, after which the bride and bridegroom started on their wedding trip to California, and will be away for about a month. Mr. Miller, who has been associated with the Western Telephone Construction Company for some time past, is a great favorite amongst the electrical fraternity in the West, and has the best wishes of his many friends for his future happiness, and that of his bride.

WASHINGTON, MO.—Mr. A. A. Tibbe, the proprietor of the Washington electric light plant is putting in a telephone exchange, which will connect with several neighboring towns.

[1]Paper read at the Institution of Civil Engineers. Engineering Conference.

LITERATURE

ELECTRIC POWER TRANSMISSION.—By Dr. Louis Bell. New York: W. J. Johnston Company, 1897. 491 pp.; 6 x 9 in. Cloth. Price, $2.50.

THIS is an excellent treatise on power transmission written by an accepted authority on electrical transmission of power. The chapter on properties of alternating current brings out with remarkable clearness without the use of mathematics, the somewhat involved effects which arise in the transmission of those currents. Under the section devoted to the commercial problem the author sounds a warning which none notes more keenly than the professional man. Regarding the questions of published costs, it may be said that they are very misleading in their direct application to practical problems, as they are usually a statement of only part of those expenses that are really incurred in power production. The upbuilding of electric plants promoted from such costs as a basis has placed the electric light and power industry in its present state of financial coma.

On the other hand, Dr. Bell, in his comparative estimate of power transmission where rope, pneumatic, pneumatic reheating and electric have been compared, has assumed the cost per year at $18 per indicated horse-power. He has based his assumption on good authority, but when we turn to actual production of the steam power horse-power per year we find that practical conditions would be more nearly approximated if a much higher figure were assumed. The cost given is for horse-power under practically 100 per cent. load factor, which is not the condition under which transmission plants operate.

As the treatise relates largely to water power developments, if $18 per year per i. h. p. can be practically realized, it limits largely the water powers which can be developed to produce a power in competition with $18 per year with steam. The development expense of the water power, and the distribution expense of the electrical energy must both be small, and the operating expense must be low in order to have a margin of profit over the assumed $18 per year, as the equality basis. This assumption does not affect largely the relations of efficiencies established by him for the various systems, because two miles is the distance assumed and is outside the profitable range of rope transmission. It is a very doubtful problem for pneumatic. Dr. Bell has only touched on one formidable opponent to electrical transmission at short ranges, and that is gas transmission for power distribution purposes and where coal is the available supply of energy. This method is the only one equitably comparable with electric transmission at two miles.

Beyond these points Dr. Bell has elucidated the problem of electric power transmission in a manner for which the profession as well as investor owes him a debt of gratitude.

H.

THE AURORA BOREALIS. By Alfred Angot. New York: D. Appleton & Co. 1897. Cloth. 12mo. Illus. 264 pp. Price, $1.50.

There is not a great deal of literature on this interesting subject, and a book so full of information as this is, therefore, very welcome. The still mysterious phenomena of the polar aurora are here analyzed and criticised; and the probability that auroras are produced by electrical discharges in very rarefied air is discussed from the different standpoints of theory and test. A valuable portion of the book is the catalogue of auroras seen in Europe below lat. 55 from 1700 to 1890. The plates of auroras are in black and white, and some of them are striking enough to make us wish for their reproduction in color, like those in Nansen's "Farthest North" from the explorer's own water colors.

PERSONAL

MR. LOUIS A. FERGUSON, of the Chicago Edison Company, who has been confined to his home for some two weeks past with a severe attack of stomach trouble, is now on the high road to full recovery, and his many friends will be glad to learn that he is able to attend to business.

EDUCATIONAL

McGILL UNIVERSITY, MONTREAL.

The Faculty of Applied Science has just issued its announcement for the session 1897-8 in a pamphlet giving in succinct, complete form all the information required by those desiring to become students or by those at all interested in the work. McGill has a magnificent equipment, an excellent teaching corps, and the conditions in Montreal are very favorable for students in the arts and sciences. The tuition fees at the University are moderate, and the apparatus placed at disposal for experimental work is probably as complete as that to be found anywhere on this continent—in some respects unequaled.

IOWA STATE UNIVERSITY.

We regret to note that the Library of the State University of Iowa, at Iowa City, has been almost entirely destroyed by fire. Mr. J. W. Rich is the librarian.

SOCIETY & CLUB NOTES

BOSTON N. B. OF ELECTRICAL WORKERS.

At the regular weekly meeting of Local Union No. 35, of Boston, National Brotherhood Electrical Workers of America, held at their hall, No. 49 Bennet street, Boston, Wednesday, June 30th the following officers were elected and installed: President, J. A. MacInnis; vice-president, D. B. Smith; recording secretary, D. A. McGillivray; financial secretary, R. H. Bradford; foreman, M. J. Sheehan; inspector, Wm. Hubbard; trustees, A. L. Sprague, J. M. Costello, J. J. Larkin; press secretary, J. F. Phelps.

Local No. 35, of Boston, is one of the largest and strongest locals of the National Brotherhood. At the present time there are two hundred and fifty members in good standing. They are affiliated with the Federation of Labor, Building Trades Council and the Central Labor Union of Boston. They have recently acquired new permanent quarters at No. 49 Bennet street, and their doors are open for the admission of all bona fide electrical workers.

CINCINNATI ELECTRICAL CLUB.

The regular monthly meeting of The Electrical Club was held on Thursday, July 1, at the club room in the College Building. Mr. H. S. Rogers, Division Engineer of the General Electric Company, presented a very interesting paper on the monocyclic system, in which he set forth in a very clear manner the various systems of alternating current transmission now in use, together with the advantages and disadvantages of each. The club has decided not to hold the regular monthly meetings during August or September, but the club room will be open at all times to members. Hugo Diemer is secretary.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE fourteenth general meeting of the Institute will be held at Greenacre-on-the-Piscataqua, Eliot, Me., on July 26, 27 and 28. The opening session will be held at 2 p. m., on Monday, July 26. The following papers will be presented: The Precision of Electrical Engineering. Inaugural address, by the president, Dr. Francis B. Crocker, of New York City. The Alternating Current Induction Motor, by Charles Proteus Steinmetz, of Schenectady, N. Y., A New Form of Induction Coil, by Prof. Elihu Thomson, of Lynn, Mass. Effect of Heat upon Insulating Materials, by Putnam A. Bates and Walter C. Barnes, of New York City. The Effect of Armature Inductance upon the Electromotive Force Curves of an Alternator, by Prof. W. E. Goldsborough, of Lafayette, Ind. Electric Metering from the Station Standpoint, by Caryl D. Haskins, of Boston, Mass. Development of the Fire Alarm Telegraph, by Adam Bosch, of Newark, N. J. Electrical Traction—Notes on the Application of Electrical Motive Power to Railway Service, with illustrations from the Practice of the Metropolitan Elevated Road of Chicago, by M. H. Gerry, Jr., of Chicago. The Cost of Steam Power, by Horatio A. Foster, of Buffalo, N. Y. Efficiency and Life of Carbons in Enclosed Arc Lamps, by W. H. Freedman, of New York City. Armature Reactions in a Rotary Transformer, by Prof. Robert B. Owens, of Lincoln, Neb. Recent Applications of Storage Batteries to Electric Railways, by Herbert Lloyd, of Philadelphia. The Economy and Utility of Electrical Cooking Apparatus, by Prof. J. P. Jackson, of State College, Pa.

In addition to the regular Institute programme, Miss Farmer has arranged for some special popular meetings and lectures on electricity and invention, in special remembrance of her father, Prof. Moses G. Farmer. Among the expected participants are Prof. Brackett, on The Past and Present Outlook of Electrical Science; Prof. Dolbear, on Moses G. Farmer as an Electrical Pioneer; Prof. Elihu Thomson, on Electricity in the Future; Prof. Anthony, on the Education of Electrical Engineers; Mr. T. Hall, on Early Electric Traction; Mr. F. J. Sprague, on the Richmond Road; while Profs. Crocker, Louis Duncan, Pupin and C. R. Cross will also participate. Secretary Pope is now issuing programmes to all the members. Copies can be had on application.

LEGAL NOTES

WENSTROM ELECTRIC COMPANY.

The Wenstrom Electric Company has filed its answer in the Circuit Court, Baltimore, by Steele, Semmes, Carey & Bond and H. Marcus Denison, attorneys, to the suit instituted by C. C. Shriver for the sale of the company's property. It is asserted in the answer that the leasing of the company's property was a wise and judicious proceeding, and that the company discontinued the active prosecution of its business because of this lease, and not because of insolvency or financial embarrassment. The answer denies that the company's factory has been abandoned or allowed to remain in a neglected condition. The company's entire indebtedness, the answer claims, is about $5,500, and its property and franchises are worth about $250,000, so that in no sense is the company insolvent.

MISSOURI CO.'S PLANT IN ST. LOUIS NOT A NUISANCE.

In the case of Annie Chamberlain against the Missouri Electric Light and Power Company, the jury found a verdict in favor of the defendant. The plaintiff owns a row of houses on Olive street, near Twentieth, nearly opposite the power plant of the defendant. She claimed that the noise, smoke and vibration of the earth caused by the defendant's plant have damaged her property, and that they cause her tenants to become dissatisfied and leave the premises. She sued for $15,000 damages. The contention was that the plant was run with due care and that it was in no sense a nuisance or detriment to the neighborhood.

THE STOCK MARKET

SPECULATION NARROW.

MIDSUMMER dullness now rests upon the markets, but with a smaller volume of business and a narrowing speculation, prices are firm. Some attention is being paid to the coal miners' strike and the effect of a short supply, but in general hopefulness prevails of an early settlement. Recently 25 per cent. of all the union engineers in England were out on strike, but the markets were all indifferent to it. The Western crop prospects are excellent and above the average. Gold exports have stopped, and early importations are looked for. General trade is quiet; the merchants all say: "What we want is orders."

Last week, 13,395 shares of Western Union were sold, closing at 84. Only 1,725 shares of General Electric changed hands, touching 34. American Bell Telephone on sales of only 513 shares was steady around 228.

COPPER: Lake copper is quoted in carload lots at 11½ cents; Western at 11¼.

RAILS: Heavy steel rails are quoted at $19 and light at $24 to $28.50.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 29, 1897.

Alarms and Signals:—

BURGLAR ALARM SYSTEM. W. T. Arnold, Chicago, Ill. Filed December 15, 1896.
A system in which objects are protected by movable covers.

ELECTRIC TRAIN SIGNAL. M. W. Parrish, Detroit, Mich., 585,342. Filed November 7, 1896.
Comprises a signal, and a muffling armature, and a permanent magnet for locking the armature.

Batteries, Primary:—

APPARATUS FOR APPLYING HEAT TO THERMO BATTERIES. H. C. Reagan, Jr., Philadelphia, Pa., 585,229. Filed May 15, 1896.
In combination with a locomtive boiler with a smoke box, a thermo battery surrounding the smoke box, a cooling device surrounding the battery and means for causing a circulation through the device.

Batteries, Secondary:—

SECONDARY BATTERY. G. E. Hatch, Quincy, Mass., 585,472. Filed April 28, 1896.
Consists in autogenously forming a porous layer of active material from the metal of the electrode by electrolytic action, then loosely confining against the porous layer, active material in a granular condition, and continuing the electrolytic action so as to effect the union of both materials.

SECONDARY BATTERY. G. E. Hatch, Quincy, Mass., 585,473. Filed April 28, 1896.
Employs terra cotta supporting plates.

ELECTRIC ACCUMULATOR SYSTEM. H. B. Cox, Hartford, Conn., 585,620. Filed Nov. 10, 1893.
System for charging a plurality of accumulators from a generator of lower voltage than the voltage of the accumulator plant by successively placing one or more of the accumulator cells in circuit with the generator for a predetermined period of time.

Conductors, Conduits and Insulators:—

EARTH CONDUCTOR OR GROUND WIRE ATTACHMENT. H. M. Crane, Boston, Mass., 585,185. Filed May 10, 1897.
A connector for attaching an electric conductor to a pipe, consisting of a metal band looped around the pipe, in combination with a holding device through which the loop passes in close contact with the pipe.

ELECTRIC CONTACT DEVICE. S. H. Stahl, Johnstown, Pa., 585,293. Filed February 23, 1897.
Comprises a plurality of spools adapted to engage opposite sides of the conductor, a jointed frame upon which the spools are carried, and a compression device adapted to exert a separative pressure upon the ends of the frame.

INSULATING JOINT. L. F. Van De Wiele, Brooklyn, N. Y., 585,321. Filed October 14, 1896.
Comprises a yoke, two insulating disks fitting upon each other, a hickey fitting between the disks insulated from the binding pin and yoke, and a binding pin carrying the insulating disks in the yoke.

Dynamos and Motors:—

COMBINED ELECTRIC FAN AND ELECTROLIER. E. H. Bennet, Jr., Bayonne, N. J., 585,250. Filed June 14, 1893.
Consists of a central shaft, supporting an electric motor, and having a portion which is revoluble thereon and which carries fan blades, and an electrolier regidly supported by the shaft and comprising a plurality of electric lamps.

DYNAMO ELECTRIC MACHINE. G. E. Dorman, Chicago, Ill., 585,379. Filed February 4, 1896.
Single phase alternating current motor.

ELECTRIC MOTOR. C. Lindberg, Duluth, Minn., 585,527. Filed February 24, 1896.
Iron clad motor adapted for the propulsion of cars or other vehicles.

ELECTRIC DYNAMO OR MOTOR. C. E. Emery, Brooklyn, N. Y., 585307. Filed April 20, 1893.
Consists of an electric dynamo or motor without field coils based on the development of the discovery that the operation of shifting the commutating brushes from mid-position through a given angle of commutation has the effect to produce a field across the armature and through the pole-pieces and yoke.

Electro-Metallurgy:—

PROCESS OF OBTAINING METALLIC ZINC AND COPPER FROM ORES. C. A. Burghardt and G. Rigg, Manchester, England, 585,355. Filed June 1, 1896.
Consists in treating the ores with an ammoniacal solution precipitating the iron dissolved in the resultant liquid by the addition of hydrated oxid of tin and recovering the zinc electrolytically.

ELECTROLYTICAL DIAPHRAGM. C. Kellner, Vienna, Austria-Hungary, 585,387. Filed August 18, 1894.
A diaphragm for electrolytic apparatus composed of a slab of soap and a suitable reinforcing backing.

METHOD OF AND APPARATUS FOR SEPARATING PRECIOUS METALS FRO MTHEIR SOLVENT SOLUTION. J. F. Webb, St. Louis, Mo., 585,492. Filed September 21, 1896.
Consists in passing the solution first in a downwardly direction through a body of carbon, then in an upwardly direction through a body of zinc, and then downwardly again through a body of carbon.

PROCESS OF OBTAINING POROUS METALS BY ELECTROLYSIS. L. Hopfner, Berlin Germany, 585,359. Filed October 5, 1896.
Consists in electrically precipitating a porous metal, and stiffening the same by precipitating thereupon a denser metal.

Lamps and Appurtenances:—

BRACKET FOR INCANDESCENT LAMP. H. Noreck, Charlottesville, Va., 585,350. Filed March 5, 1897.
Comprises a tubular section through which the wires extend and an overlapping guard forming a hood adapted to receive the socket.

ELECTRIC ARC LAMP. C. J. Toerring, Jr., Washington, D. C., 585,603. Filed January 2, 1896.
Feed mechanism for enclosed arc lamps.

ELECTRIC ARC LAMP. P. H. Klein, Jr., New York, 585,316. Filed March 20, 1897.
Air tight joint for attaching the lower carbon in enclosed arc lamps.

ELECTRIC ARC LAMP. P. H. Klein, Jr., New York, and E. Lavens, Brooklyn, N. Y., 585,317. Filed November 9, 1896.

ELECTRIC ARC LAMP. E. Lavens, Brooklyn, N. Y., 585,318. Filed March 20, 1897.
Similar to No. 585,316.

Measurement:—

ELECTRIC METERING APPARATUS. E. P. Cox, Lynn, Mass., 585,258. Filed March 6, 1897.
Comprises apparatus having a number of registering devices, one part of which is always connected to the motor mechanism and registers the whole amount of energy used, and means for throwing the other part of the registering device out of and into operation at predetermined times.

ELECTRIC METER. E. P. Cox, Lynn, Mass., 585,257. Filed March 6, 1897.
Comprises a meter for registering at different times, consisting of a single motor mechanism and single registering mechanism, and means for controlling the speed of the motor for a given load from a point distant from the meter.

Miscellaneous:—

ELECTRIC CLOCK. R. Baumann and T. H. Wurmb, St. Louis, Mo., 585,249. Filed May 18, 1896.
Consists of an electromagnet provided with a rocking armature, having a side pull and which operates through its connections the hands of clocks, at times determined by a master clock.

GROUND DETECTOR. E. W. Rice, Jr., Schenectady, N. Y., 585,287. Filed March 1, 1897.
An instrument of the static type for alternating circuits.

ELECTRIC TOWER CLOCK. T. H. Wurmb and R. Baumann, St. Louis, Mo., 585,301. Filed May 18, 1896.
Details of construction.

Electric Heating:—

ELECTRIC BROILER. G. B. Fraley, Denver, Colo., 585,308. Filed October 28, 1896.
Employs a rotatable shaft on which the broiler is supported, suitable bearings for the shaft and means for conducting electricity to the broiler in whatever position it may assume.

ELECTRIC HEATER. G. B. Fraley, Denver, Colo., 585,309. Filed October 28, 1896.
Comprises a block having a channel therein, elements of conductive material located in the block, a chamber in the rear of the channel, and in communication with the latter, and means for causing the elements to always contact with each other.

ALTERNATING CURRENT ELECTRIC HEATER. G. B. Fraley, Denver, Colo., 585,310. Filed April 27, 1897.
Comprises a closed circuit secondary coil surrounded by a primary coil in inductive relation to it, and means for putting the latter in circuit with a source of alternating current.

ELECTRIC HEATER. G. B. Fraley and A. B. Paulson, Philadelphia, Pa., 585,311. Filed September 21, 1896.
Adapted for use with either direct or alternating currents.

Railways and Appliances:—

CONTACT BOX FOR ELECTRIC RAILWAYS. W. M. Brown, Johnstown, Pa., 585,255. Filed July 18, 1896.
Employs a sealed vessel removably secured within the box containing a switching mechanism consisting of a solid conductor floating or immersed in a liquid conductor.

ELECTRIC TROLLEY DEVICE. A. J. Gairing, Johnstown, Pa., 585,267. Filed December 26, 1896.
Comprises diverging upwardly pressed arms, a guide, a post adapted to slide in the guide, and pivotal connections from the post to the diverging arms.

TROLLEY GUARD. W. C. Dunham, Indianapolis, Ind., 585,380. Filed December 27, 1895.
A device provided with fingers and located alongside the wheel with its catching-face normally below the groove in the trolley wheel and arranged to rise above the groove by force imparted from contact with the wire after catching it.

TROLLEY FOR ELECTRIC CARS. J. C. Kellogg, Lexington, Ky., 585,579. Filed September 25, 1896.
Embodies upwardly flaring arms pivotally connected intermediate their ends to the trolley axle and adapted to engage the wire when the trolley leaves it.

TROLLEY FOR ELECTRIC RAILWAYS. V. Thelin, Geneva, Switzerland, 585,602. Filed November 30, 1896.
Consists of a bow-shaped sliding contact automatically reversible on a change of direction of the car.

Switches, Cut-Outs, Etc.

RHEOSTAT AND CIRCUIT CONTROLLER. H. W. Leonard, East Orange, N. J., 585,444. Filed November 24, 1896.
Comprises an electroresponsive device connected across the circuit and arranged to hold the circuit controller in its closed position and means for opening the circuit of the device to effect the release of the circuit controller.

CIRCUIT BREAKER FOR ELECTRIC WIRES. A. J. Clark, Lexington, K., 585,507. Filed November 21, 1896.
Comprises vertical levers, each having a contact plate extended from its lower end and at right angles to the levers, and a block of insulating material to which the upper ends of the levers are pivoted.

CIRCUIT CONTROLLER FOR ELECTRIC MOTORS. H. H. Cutler, Chicago, Ill., 585,511. Filed January 8, 1897.
Combined motor starter and automatic circuit breaker.

CIRCUIT CONTROLLER FOR ELECTRIC MOTORS. H. H. Cutler, Chicago, Ill., 585,512. Filed January 8, 1897.
Similar to above.

Telegraphs:—

TELAUTOGRAPH. L. O. McPherson, Highland Park, Ill., 585,319. Filed November 24, 1896.
Employs a governor operating to change the strength of current

on line to compensate the effects of changes in frequency of the pulsations.

Telephones:—

ELECTRIC TELEPHONE. C. F. Dunderdale, Chicago, Ill., 585,560. Filed January 7, 1895.
Comprises a gravity switch consisting of a chamber divided into two compartments, located in the interior end of the receiver, a movable ball contact maker normally resting within one compartment of the chamber when the receiver is not in use, and completing the circuit in the other chamber when the receiver is shifted.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 6, 1897.

Alarms and Signals:—

RAILWAY SIGNALING SYSTEM. H. Bezer, New Rochelle, N. Y., 585,733. Filed April 22, 1895.
Means whereby the dispatching signal cannot go to "safety" until the detaining signal has gone to "danger" and the detaining signal cannot go to "safety" until the dispatching signal has gone to "danger."

Batteries Primary:—

REVERSIBLE PRIMARY BATTERY. L. W. Pullen, Camden, N. J., 585,699. Filed Oct. 23, 1896.
Comprises a cathode, a depolarizing mass in contact therewith and consisting of a mixture of finely divided carbon, a salt of manganese and concentrated sulfuric acid uniformly distributed throughout the mixture and an anode arranged in a dilute electrolyte.

GALVANIC BATTERY. J. Sully, New York, 585,854. Filed Oct. 27, 1896.
Composed of a negative, porous, gas-coke, carbon, cylindrical containing vessel, and a positive zinc pencil immersed in an electrolytic fluid of carbonate of potash and kerosene oil, contained within the carbon vessel, and resting in a small quantity of quicksilver contained within an insulation in the bottom of the vessel.

GALVANIC BATTERY. J. Sully, New York, 585,855. Filed Feb. 16, 1897.
Similar to above.

Batteries Secondary:—

SECONDARY BATTERY. I. Samuels, New York, 585,853. Filed Aug. 11, 1896.
An element, comprising a plate of active material, a terminal embedded therein, and a telescopic case of conducting material, inclosing the terminal, the case being connected to or forming a part of the terminal.

ELECTRIC STORAGE OR SECONDARY BATTERY. F. King, London, England, 586,044. Filed Jan. 26, 1897.
An element consisting of a plate having perforations therethrough containing active material, and having applied to its sides an adherent coating of india-rubber, perforations being made through the rubber and through the active material, so that the electrolyte may have access to the active material through the perforation.

Conductors, Conduits and Insulators:—

JOINT OR SPLICE FOR ELECTRIC WIRES OR CABLES AND METHOD OF MAKING SAME. F. Schwedtmann, St. Louis, Mo., 585,707. Filed Dec. 14, 1896.
Consists in forming hooks in the ends of the wire, interlocking the hooks, and then molding a conducting metal around them.

ARMORED ELECTRICAL CONDUIT. E. T. Greenfield, Brooklyn, N. Y., 585,863. Filed Oct. 7, 1896.
Consists of an external metallic armor and an internal tube of insulating material which is impervious to moisture.

ARMORED ELECTRICAL CONDUIT. E. T. Greenfield, New York, 585,864. Filed Dec. 10, 1896.
A conduit tube composed of a metal armor and an interior lining of oilcloth with the painted surface thereof adhering to the inner wall of the armor.

Dynamos and Motors:—

BRUSH HOLDER. H. Geisenhöner, Schenectady, N. Y., 585,746. Filed Nov. 20, 1896.
Comprises a rotatable stud, one or more brush holders adapted to be rotated on and adjustably held in fixed position on the stud, and means for adjustably holding in fixed position the stud.

ELECTRIC MOTOR FOR ELEVATOR. J. H. Ihlder, Yonkers, N. Y., 585,760. Filed Aug. 11, 1896.
Consists of a motor in which the current through the armature is reversed, a series field in sections, one section of which is reversed with the reversing of the armature.

BRUSH HOLDER FOR DYNAMO ELECTRIC MACHINES. R. Lundell, Brooklyn, N. Y., 585,872. Filed July 11, 1896.
Employs a stationary guideway for the brush and a movable part adapted to bear against the brush in two directions.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. J. J. Walsh, Paris, Texas, 585,726. Filed July 29, 1896.
Comprises a pair of escapement wheels arranged on one shaft, the teeth of one wheel alternating with those of the other, and pendulum governed escapement dogs alternately coacting with the escapement wheels, the dogs being mounted to swing independently one of the other.

MANUFACTURE OF INCANDESCENT LAMPS. J. W. T. Olan, New York, 586,055. Filed March 13, 1893.
Consists in introducing alkali metal into the lamp and exhausting and sealing the lamp while alkali metal is still contained therein.

Measurements:—

ELECTRICITY METER. A. W. Staveley, I. H. Parsons and T. J. Murday, Leicester, England, 585,892. Filed Jan. 5, 1897.
Recording apparatus for ammeters.

Miscellaneous:—

ELECTRICAL ATT[illegible] MUSICAL INSTRUMENTS. W. B. Fleming, Detroit, Mich., 585,663. Filed Jan. 13, 1897.
Method of operating electrical pianos comprising a roller, a conductor in electrical connection therewith, a shaft provided with a series of discs adjacent to the roller, insulated one from the other, and spring contact arms in electrical connection with the discs.

APPARATUS FOR ELECTROLYTICAL DECOMPOSITION OF SALT SOLUTIONS. C. Kellner, Vienna, Austria-Hungary, 585,959. Filed Feb. 24, 1896.
Comprises a vessel containing a solution of common salt, one or more groups of electrodes rigidly connected together by non-conducting connections, and suitable electric conductors for the first and last of the series of plate electrodes.

Railways and Appliances:—

RAILWAY DANGER SIGNALING. J. K. Kendrick, Germantown, Cal., 585,676. Filed Nov. 2, 1896.
Employs a pilot car carrying a cow catcher adapted to sound an alarm in the locomotive cab when anything comes in contact with the pilot car cow catcher.

ELECTROMAGNETIC AND MECHANICAL BRAKE. J. E. Parker, Bayonne, N. J., 585,973. Filed Dec. 17, 1895.
Details of construction.

Regulation:—

ELECTRIC CONTROLLER. A. F. Macdonald, Schenectady, N. Y., 585,772. Filed Jan. 5, 1897.
Comprises a single set of moving contacts, two sets of brushes mounted for dissimultaneous engagement therewith, the two sets of brushes establishing different circuit combinations of the dynamo electric machines, and means for changing the relation between the contacts and sets of brushes.

Switches, Cut-Outs, Etc.:—

AUTOMATIC CUT-OUT. C. N. Black, New Haven, Conn., 585,904. Filed March 15, 1897.
Combines with a dynamo electric machine having two or more independent armature circuits, two or more independent lamp circuits connected in series with and between the independent armature circuits of the machine, and automatic cut-outs corresponding in number to the independent lamp circuits which they are placed across and each providing a non-inductive path and operating to short circuit the respective lamp circuits when the voltage therein exceeds a predetermined limit.

ELECTRIC SWITCH. F. D. Hall, Syracuse, N. Y., 586,029. Filed March 8, 1897.
Details of construction.

ELECTRIC SWITCH. E. Oxley, Washington, D. C., 586,075. Filed April 23, 1897.
An automatic switch for systems of distribution in which a balance must be preserved between the sides of the systems.

Telephones:—

TELEGRAPH SWITCH. J. S. Allen, Halsey, Neb., 585,731. Filed July 25, 1896.
Comprises an instrument cut-out of non-fusible properties and a lightning arrester.

Telephones:-

SWITCHBOARD FOR CENTRAL TELEPHONE STATIONS. C. E. Egan, Chicago, Ill., 585,662. Filed Dec. 2, 1895.
Comprises flexible arms having sockets mounted thereon and contact points on each side included in the circuit of the signaling apparatus.

TELEPHONE TRANSMITTER. E. C. Wilcox and B. L. Lawton, Meriden, Conn., 585,896. Filed Aug. 31, 1896.
Employs a carbon conducting diaphragm interposed between the body and cap, and an annular elastic conducting washer bowed flatwise to produce a plurality of contact points, and arranged between the body and the cap so as to make a plurality of engagements with the diaphragm.

OPERATOR'S SWITCH FOR TELEPHONE EXCHANGES. L. Johnston, La Crosse, Wis., 585,915. Filed March 13, 1897.
Provides means to change the respective telephonic circuits through the medium of a single circuit changing cam which controls all of the contacts.

NEWS AND NOTES

JUBILEE ILLUMINATIONS IN LONDON.

Great use was made of electricity for illumination purposes in England the night of the Jubilee. The biggest piece of work was that of concentrating the beams of seventy searchlights on the dome of St. Paul's Cathedral. This performance, which produced wonderfully fine results, cost $6,000.

THE LATEST POWER PROJECT FOR NIAGARA.

Work was begun July 9 on the Canadian Power Company's power canal. The plans for the work were approved by Hon. Andrew G. Blair, Minister of Railways and Canals for the Dominion of Canada, and the work commenced is on section A of the canal, near the village of Chippawa. Surveys for the entire canal are nearly completed, and as soon as done work will be prosecuted all along the line. The canal will extend from Chippawa Creek to the head of Cedar Island. A. C. Denison, of Philadelphia, Pa., and Banker R. Paine, of Niagara Falls, Ont., represent the power company. The contractor in charge is Charles H. Morse, of Niagara Falls, South, and the engineer is Walter McCulloch, of this city. The waterway will be 15 feet deep, coming out on the bluffs near the head of the Dufferin Islands, not far from the Horseshoe Fall, into which the water will return at the level of the upper river. It is said that 40,000 h. p. can be developed, and that from 5,000 to 10,000 h. p of direct power will be used without the intervention of electricity.

TRADE NOTES & NOVELTIES

APPARATUS WANTED.

The Wicomico Falls Milling and Electric Company, Salisbury, Md., R. M. and W. T. Johnson, proprietors, are in the market for two 45 or 60 k. w. slow speed multipolar machines, or will be satisfied with Edison dynamos if in good condition. They add: "We take your paper and like it very much."

KEYSTONE ELECTRIC CO.

Mr. F. B. Downing, vice-president of the Keystone Electric Company, of Erie, Pa., informs us that the concern have been working twenty-four hours a day, and that during the past six months they have had more men in their employ than at any other previous time since their organization. Orders have been filled recently from all parts of the country, and many are in hand from abroad, countries as far away as Austria ordering apparatus. The orders range over a wide variety of apparatus, including small motors for machine tools for direct connection, required by the Union Iron Works, of San Francisco, to large railway generators of 200 horse-power for an Eastern trolley road; also a large number of special reversible motors with controllers for direct connected electric elevators.

RIDGWAY DYNAMO AND ENGINE CO.

Mr. Cyrus Robinson, general manager of the Ridgway, Pa., Dynamo and Engine Company, makers of the McEwen engine and the Thompson-Ryan dynamo, has just returned from quite an extensive trip through the East and West and has found the prospects of business unusually bright. Below is a list of sales for the end of June: One tandem compound engine, for Purdue University; one 150 kilowatt plant, for Northwestern Mining and Exchange Company; two 75 kilowatt D. C. plants, for the University of Michigan; two 50 kilowatt generators, for the City of Buffalo, N. Y.; two 75 kilowatt generators D. C. to tandem compound engines, for Tulane Hotel, Nashville, Tenn.; one 10 kilowatt plant, for W. H. Brown & Son, Pittsburg, Pa.

The order for the plant to go in the University of Michigan is particularly interesting. The plant is to be connected up on the Arnold system, so that either generator can be run by either engine. There were no fewer than 23 firms figuring on this plant, and Mr. Robinson and his company feel therefore a very excusable pride in having captured the entire contract.

EIGHTY MILE TRANSMISSION IN SOUTHERN CALIFORNIA.

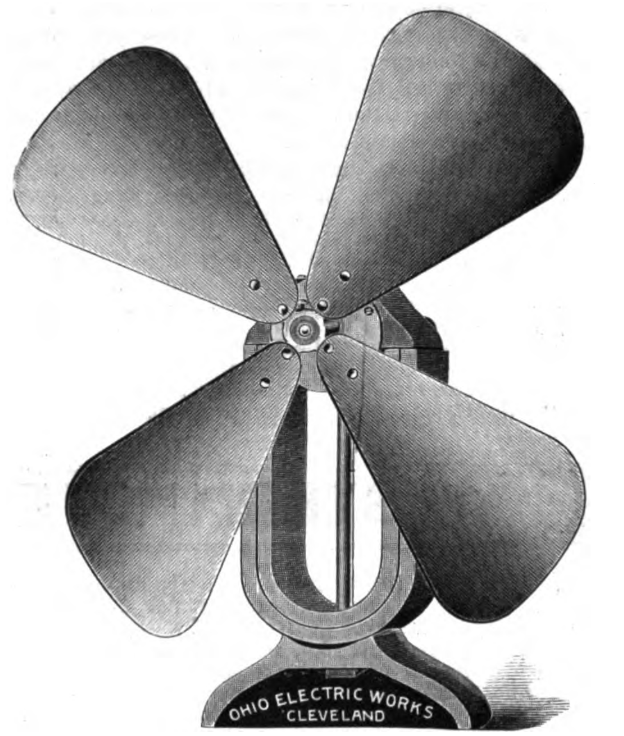
A CONTRACT for the transmission of power of the river running through the Santa Ana Canyon to Los Angeles and Pasadena, a distance of eighty miles, has been concluded between the Southern California Power Company and the General Electric Company. The amount of power to be transmitted at first is four thousand horse-power. The station will be located in the Santa Ana Canyon, twelve miles from Redlands and about eighty miles from the towns in which the electric power will be utilized. The water will be taken from the river through canal, flume and tunnel along the side of the canyon. Here it will be led into a pipe line 2,200 feet long, giving what will be equivalent to a vertical fall in the water of 750 feet.

The wheels will be of the impact type, directly connected to the generators, of which there will be four, each of 750 kilowatt (1,000 horse-power) capacity. The maximum line potential will be 33,000 volts, to which potential the initial voltage will be raised by twelve 250 kilowatt step-up transformers.

This transmission is the longest commercial electrical power transmission as yet undertaken, as well as that using the highest voltage. At present the longest is that transmitting the power of the waters of the Ogden Canyon in Utah to Salt Lake City, a distance of 36 miles. The Los Angeles transmission will be over twice that distance, and three times the longest distance yet tried with the power of Niagara, which to date has only been transmitted commercially to Buffalo, a distance of 26 miles, although at the time of the New York Electrical Exhibition it ran a small Tesla motor there, the distance being about 465 miles.

THE OHIO ELECTRIC WORKS FAN OUTFIT.

THE Ohio Electrical Works, of 813 South Water street, Cleveland, Ohio, the well known manufacturers of electric bicycle lamps and other electrical novelties, have placed on the market a decided novelty in the shape of the battery fan motor outfit illustrated in the accompanying engraving.



Ohio Electric Works Fan Motor.

In order to economize in battery power the field is created by a pair of permanent magnets fixed to the base, with the armature at the upper ends. The fan has 10-inch blades. Several hundred of these fans were sold last season and a greatly increased demand is confidently looked for this season. The company also furnish batteries for running the outfit.

THE CATARACT CONSTRUCTION CO.

At a meeting of the Cataract Construction Company directors, held in their office in the Mills Building, New York, the following officers were re-elected: President, Edward D. Adams; first vice-president, Francis Lynde Stetson; second vice-president, Edward A. Wickes; secretary and treasurer, William B. Rankine.

At the same time the directors of the Niagara Junction Railway and the Niagara Development Company held meetings and elected as their officers the officials of the Cataract Construction Company.

DIRIGO TELEPHONE CO. OF MAINE.

The stockholders of the Dirigo Telephone Company, of Maine, met at the office of J. J. Linscott, Farrington, on June 24, to act upon four special articles, namely: 1. To see if the corporation will reduce its outstanding capital stock from $500,000 to $100,000, in order to provide for an issue of preferred stock to obtain working capital. 2. To see if the corporation will authorize an issue of $50,000 of preferred stock at par, to fix the rate of maximum dividend thereon, to determine how the net earnings shall be divided between the preferred stock and the common stock and to fix the right of each class of stock in case of a future sale of all or part of the assets of the corporation. 3. To see if the corporation will authorize the directors to extend the business of the company and to establish and purchase new lines. 4. To elect a secretary to fill a vacancy in said office of secretary.

The meeting decided to adopt an aggressive policy while on the articles definite action will be taken at the annual meeting in July, when the new officers will be chosen, influential men having consented to accept office.

UNDERGROUND TELEPHONE CABLE WORK IN ST. LOUIS.

The first large underground work in St. Louis is now under way, and the Standard Underground Cable Company has recently secured from the Bell Telephone Company, of Missouri, and the Kinloch Telephone Company (both of St. Louis) two of the largest contracts ever let in this country (and probably in the world) for telephone cables; these two orders comprising all the underground cables in St. Louis yet contracted for, and constituting the complete cable equipment for both telephone companies. Both contracts were secured in the face of the most severe competition.

To fill these contracts there will be required more than 650,000 feet of cable, which, in turn, requires about 100,000,000 feet of No. 19 B. & S. G. copper wire, and 2,000,000 pounds of lead. To meet this extraordinary demand, the manufacturing facilities of the Standard Company in the paper-covering department, have recently been doubled.

Considerably more than one-half of this cable will be installed by the Standard Co., they having contracted to turn the cable system of the Kinloch Company over to that company complete and ready for service. A large force of expert workmen will be employed for nearly a year in this work, under the direct supervision of the St. Louis office.

WESTERN NOTES

MR. EDWARD C. BROOKS has been appointed manager of the Chicago office of the American Circular Loom Company, of Boston, Mass., in place of Mr. A. D. Chandler, who is no longer with the company. Mr. Brooks is a brother of Mr. H. H. Brooks, manager of the head office of the concern in Boston, who is also very well known in the West where he made a host of friends while staying there some time ago.

THE REPLOGLE GOVERNOR WORKS, of Akron, O., are now building a full line of water wheel governors purely mechanical in their operation, but retaining the extreme sensitiveness of their well known electrical water wheel governor.

INTERNATIONAL ELECTRICAL PURIFYING COMPANY has been formed at St. Louis, Mo., with a capital stock of $10,000, fully paid up, to erect electric plants to purify water. D. Reynolds, W. H. Niebling, E. H. Johnson and L. E. Walther are directors.

THE HIGHLAND ELECTRIC SOLDERING PASTE is meeting with very great favor as a soldering flux. It is put up in very convenient form for use, and certainly makes a very successful joint. The Electric Appliance Company, of Chicago, who handle this soldering paste in the West, are sending out small sample boxes. They state that the samples they have distributed have already resulted in the sale of several hundred pounds of the soldering paste, and that every customer is highly pleased with the work they can do with this flux.

ADVERTISERS' HINTS

THE ARMORITE INTERIOR CONDUIT COMPANY, Pittsburg, Pa., illustrate the new Girard office building, Philadelphia, in which 200,000 feet of "Armorite" interior conduit was laid.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., cite another instance where the result confirms their theory on the utilization of waste steam in central stations.

THE ELECTRIC APPLIANCE COMPANY, Chicago, Ill., advertise the "Reliance" iron box bell as the best of all.

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., continue to supply renewed incandescent lamps at 12 cents and state that the results obtained by their use justify their claims of long life, efficiency and cheapness.

A. L. McRAE, consulting electrical engineer, 306 Oriel Building, St. Louis, Mo., will be glad to correspond with parties desiring estimates, plans, specifications, examinations, reports, tests, etc.

A. & J. M. ANDERSON MANUFACTURING COMPANY, 289-293 A street, South Boston, Mass., advertise lightning arresters, quick break switches and switchboards.

NEW YORK NOTES.

BEACON LAMP COMPANY, New Brunswick, N. J., have sent out a handsome 32 page catalogue of their incandescent lamps, Crookes tubes, lamp bases, etc.; also a revised price sheet of their standard copper tipped fuse links. The Beacon lamps are made with mechanical pumps, and in no case do they use mercury. They invite special attention to their series, miniature and multiple lamps.

LONG ISLAND, N. Y. Nathan C. Jessup has given his consent for the proposed trolley from Riverhead, L. I., to pass through his valuable lands, also across his now famous bridge to the ocean, cutting his fields of unripe grain so as to cause no delay. This gives the trolley company a direct route to the ocean.

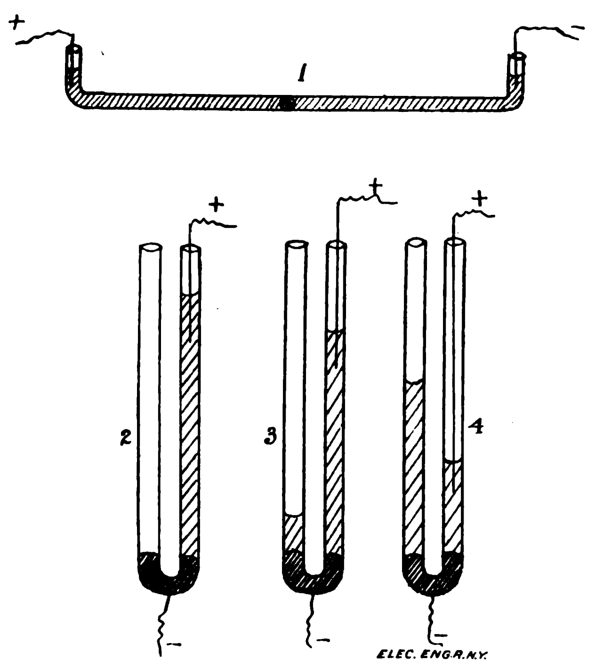
MISCELLANEOUS

A NEW EXPERIMENT IN ELECTRO CAPILLARY PHENOMENA.

BY JOSEPH W. HARRIS.

IN the well known electro-capillary experiments a drop of dilute acid is usually placed in a horizontal tube having ends bent up, and remainder of tube on each side of drop filled with mercury, or, sometimes the tube is filled with dilute acid and a globule of mercury placed in center of tube (see Fig. 1). A current passed between terminals of the latter causes the globule of mercury to move towards the negative electrode. The movement is usually ascribed to formation of gases by electro-decomposition.

In the following experiment which, I believe, has not before been published, a glass U-tube with a platinum terminal sealed in at the bend, has sufficient mercury poured in to seal off both limbs, and in one limb is poured a not too strong solution of a salt. I used solution of ammonium chloride and potassium sulphate. A current passed through the liquid with



FIGS. 1, 2, 3 AND 4.

the mercury negative (see Fig. 2) causes decomposition of liquid and forms an amalgam of ammonium or potassium, according to the salt used, and this amalgam, during passage of the current, permits the transmission of the liquid from one tube to the other, as shown in Fig. 3. That the transmission of the liquid is not due to hydrostatic pressure but to electric action can be seen by continuing the experiment for some time, when the liquid will rise to a higher level in the former empty tube than it is in the right hand tube, as seen in Fig. 4. The mercury also increases in bulk and absorbs considerable heat.

During the passage of the current the mercury acquires a frosty appearance, and one can almost see the minute drops of liquid moving through it. The solution before experiment had a neutral reaction to litmus paper, but after the experiment the solution in the limb submitted to electrolysis had an acid reaction, and the transferred liquid an alkaline reaction. The odor of peroxide of nitrogen can be readily detected among the gases given off during decomposition. On breaking the current the ammonium amalgam is decomposed by the acid liquid in the right limb, and a stream of gas bubbles is given off, the mercury reducing in volume to its former amount.

Potassium sulphate does not give such good results as ammonium chloride.

STORAGE BATTERY ENGINEERING PRACTICE.—XVIII.

BY JOSEPH APPLETON.

(COPYRIGHT, 1897.)

STORAGE BATTERIES IN CENTRAL STATIONS—(Continued).

THERE is one application of storage batteries in connection with direct current central stations which differs from any of the foregoing. It is the outcome of the numerous efforts to straighten out the load curve, and utilize the generating plant during the hours of light load. This system will undoubtedly become a very important feature of modern central station practice when its advantages are fully recognized, as it solves two different problems, viz., equalizing the load on the generating plant by relieving it of a portion of the peak, and providing additional load during the hours of minimum load; also preventing the installation of private generating plants in opposition to central station supply.

There are many buildings, chiefly office buildings and stores of a certain class, which have a great number of lamps installed, but only use them for a few hours a day, and that at a time when the maximum load occurs at the central station. These customers are not profitable to the electric light companies, for they take current at the time when it is most valuable and nevertheless expect the lowest rates on account of the large number of lamps used; yet there is the possibility of this large number of lamps being suddenly thrown on the system in the case of a thunderstorm, etc. In addition to this, these buildings are now using electric elevators which are a disturbing element on any central station system and have to be accepted with certain limitations; but with this application of storage batteries these objectionable features are removed.

The conditions under which central stations are compelled to accept customers of this class, often force the latter to install their own generating plants, which means a loss of business to the electric light companies, while with this system they can furnish current at a cheaper rate than to the ordinary consumer and yet find it a most profitable business. If a storage battery is installed in a building of this description it entirely alters the conditions. The battery can be charged from the central station when additional load is wanted, and will furnish current for the building during the hours of maximum load, or, in other words, turns an unprofitable customer into a most desirable one. Besides this, the central station has the advantage of these batteries being connected to its system at various points, thereby equalizing the pressure over the entire system.

One of the large electric light companies in this country, which was the first to adopt this system, states that current is worth to them, to sell, during the hours of maximum load three to four times the amount at any other time of the day, and that by this system they can generate current at the cheapest time and sell it at the time of maximum value at a price profitable to both themselves and the customer; moreover, every battery of this description installed relieves their distributing system of just so much load at the time of demand, and enables them to keep a more regular pressure over the whole of the system. They also believe that this system will entirely prevent the installation of private plants in their territory.

From the consumers' point of view the matter is equally satisfactory; the cost of the battery is much less than that of a complete installation, while the attention required is practically nil. The net cost to the consumer of the light supplied under this system is considerably less than if he generated the current with his own plant or took it from the central station on the most favorable terms. The service obtained under this system is very reliable, the current obtained from the storage battery being independent of any abnormal conditions which may be forced upon the central station at times of maximum load, tending to make the supply irregular.

As previously stated, the storage battery is not liable to sudden failure or breakdown, as is the case with moving machinery where the supply of current may be interrupted instantly. In the event of overwork or neglect the storage bat-

tery will deteriorate more quickly than under proper conditions, but will not fail absolutely without ample warning.

One point which commends this system to consumers in comparison with a private generating plant is the economy in space. A generating plant requires space which is valuable for other purposes, and cannot be relegated to portions of the building which are easily spared; the question of safety, vibration, light and ventilation, etc., being of paramount importance. On the other hand, a storage battery can be located in any space, where there is ample room, ventilation being the only important point to be considered, and this is much more easily carried out than with a complete generating plant.

The method of operation under this system differs somewhat with the local conditions, but generally speaking it is as follows: The battery is charged during the hours of minimum demand on the central station, the necessary increase in voltage being obtained by means of a booster installed with the battery. While the battery is being charged the consumer's circuit is connected directly to the central station system so as to avoid any complications in regard to regulation of pressure while the battery voltage is rising as the charge progresses.

In one case, with which the writer is familiar, the booster is not needed, the charging of the battery being accomplished by means of a pair of feeders which run directly to a junction box outside the consumer's building, and are so arranged that during the hours of light load they can be disconnected from the system and used as special charging feeders for the battery.

In this case the pair of feeders is connected at the station end to the high voltage charging bus used for charging the battery installed in the station, the charging of the consumer's battery being also regulated from the station. In several cases where this system is employed the central station undertakes the entire care and maintenance of the consumer's battery; in fact they place the meter between the battery and the building circuit, thus charging only for the current actually consumed, and not for that used for charging the battery; in other words, the electric light company is willing to stand the loss in the battery, simply charging the customer for the actual amount of current consumed.

It is the firm opinion of the writer, that this system will be used to a very large extent, now that the reliability of the storage battery is established in this country. It enables the electric light companies to compete with large private installations without adding to their maximum load and raises the load factor of their stations considerably. From the consumer's point of view it means an absolutely reliable service at a moderate cost without trouble or risk and occupation of space otherwise valuable.

A METHOD OF DETERMINING MAGNETIC HYSTERESIS LOSS IN STRAIGHT IRON STRIPS.[1]

BY DR. J. A. FLEMING.

THE author's process is based upon the use of the bifilar reflecting wattmeter. The samples of iron, large or small, in the form of straight strips, are inserted in a long solenoid. The solenoid is traversed by an alternating current, and the square roots of the mean square values of the current are determined by a Kelvin balance. A flat bobbin of fine wire may be slided along the strip; an electrostatic voltmeter connected to the ends of this exploring coil gives the square roots of the mean square values of the electromotive force in that coil. From these measurements and the known dimensions of the solenoid and coil, the induction density, B, can be found at any point of the length of the strip. From these results a curve is drawn, co-ordinating the values of B to corresponding distances along the half-length of the strip. Assuming the hysteresis loss per cycle, per cc. of iron, to vary as the 1.6th power of the maximum induction density, and then raising all the B ordinates to the 1.6th power, and plotting a new curve over the first, another curve is obtained which represents the variation of hysteresis loss per cc. of iron from point to point along the half-length of strip. Now, at some point along the half-length of strip there must be a section where the induction density is B_1, such that the true mean hysteresis loss for the whole bar is proportional to $B_1^{1.6}$. Let this value of the induction density be called the "effective value," and the corresponding point in the strip the "effective point." Let $M \,.\, B^{1.6}$ stand for the mean ordinate of the curve representing the varying values of $B^{1.6}$ all along the half-length. Then, evidently, $B_1 = \sqrt[1.6]{M.B^{1.6}}$.

The following curious expermental result is found: Whatever may be the length or section of the iron strip, the point at which the actual induction density has a value equal to the "effective" value always comes at the same proportional distance from the center of the strip. This distance is very exactly equal to 0.56 of the half-length, as measured from the middle; or 0.22 of the whole length from one end. If, therefore, the secondary coil is placed at that spot, and the secondary voltage then observed is used to calculate the induction density, the value so obtained corresponds to the true mean value of the varying hysteresis loss per cc. all along the strip.

Mr. Carter asked whether roots other than the 1.6th gave a similar constant value of the induction intensity.

Dr. Fleming said it seemed to be the result of accident that the 1.6th root gave a constant value for iron.

[1]Abstract of paper read before the Physical Society.

FREQUENCY TRANSFORMATION.[1]

BY LIEUT. F. JARVIS PATTEN.

AT times we would like a comparatively high frequency for one use and another relatively low one for another on the same circuit, but at present we cannot have both from the same generator; thus compelling a sort of compromise in the selection of the frequency that a system of distribution shall be given, and this necessarily to the disadvantage of some part thereof. For power distribution, we should prefer a comparatively low frequency for motors rather below sixty than above, but so low a rate is not the best for lighting; hence, the compromise, if both are to be operated from the same circuits.

Probably the chief reason why frequency transformation has not been more seriously considered is because no really good or simple solution of the problem has yet been presented; all thus far published being burdened with a complexity of commutating devices, rings and revolving brushes that render such systems altogether objectionable. I think I was the first to show a system of frequency transformation, in a paper before the American Institute of Electrical Engineers, in 1891.

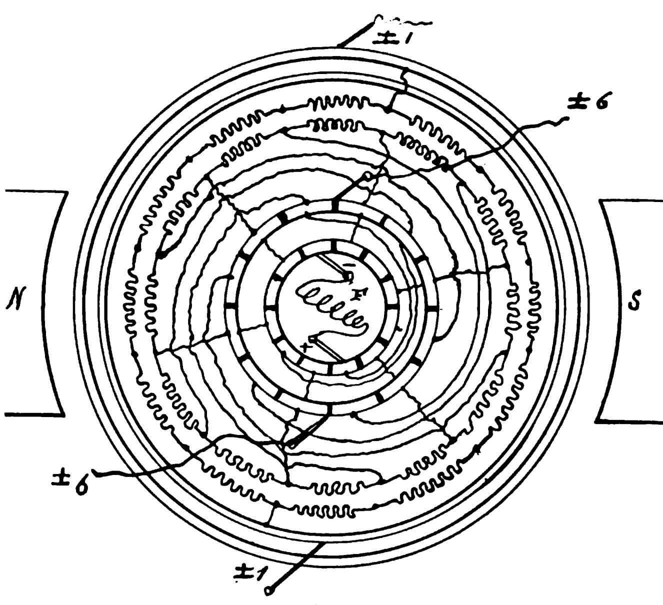


FIG. 1.

The essential features of that system are shown in Fig. 1. Briefly, a Gramme armature has a primary winding so connected to its commutator that it will turn through a certain arc, say, one-sixth of a revolution for each cycle of the alternating current, while a secondary winding of the same ring has two diametrically opposite points, connected each to a ring collector. The system by which the primary winding is connected to its commutator makes such a motor self-starting with a single phase supply, and a second commutator, reversely connected to the first at alternate segments gives a direct current for the field excitation. This apparatus will transform a single-phase alternating current of a given frequency to either single or multiphase alternating currents of one-sixth the given irequency. I need hardly say, however, that, simple as this may seem on paper, the two commutators

[1]Read before the N. E. L. A., Niagara Falls. Abstract.

render the device unacceptable to American practice, and no machine with even a single commutator or revolving brush can be regarded as a solution of this apparently difficult problem.

A frequency transformer should be a self-contained apparatus, in which all the parts are electrically or magnetically interdependent, the function of which is to induce in a secondary circuit an electromotive force of different periodicity

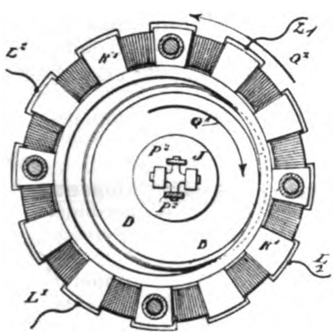

FIG. 3.

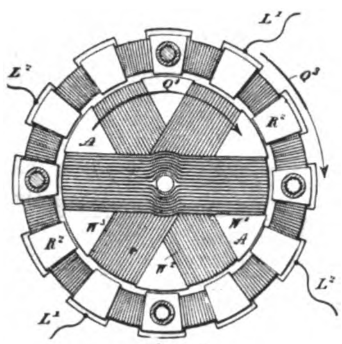

FIG. 4.

from that of the primary or inducing circuit and source of supply. Inasmuch as frequency is always the result of a relative motion of one part of a generating apparatus with respect to another, thus setting up a corresponding rate of change of induction, so it may be presumed true that changing the frequency of alternating currents implies changing the relative motion of inducing and induced parts with respect to each other, from which it may be further inferred that a moving part is indispensable.

In the apparatus I shall now describe, I obtain this change in the rate of induction by a novel form of electromagnetic motor, which is an independent part of the transformer system, and which, in conjunction with the currents of altered frequency, determines the degree of transformation. A brief description of this motor is necessary to a clear understanding of the apparatus. It is shown in vertical elevation in the lower half of Fig. 2, and in horizontal projection in Fig. 3. Its field consists of a toothed iron ring with a Gramme winding, supplied with multiphase currents through the leads L^1 L^2, setting up a rotating magnetic field in the ring. The armature is a solid iron disc, D, Figs. 2 and 3, about the same

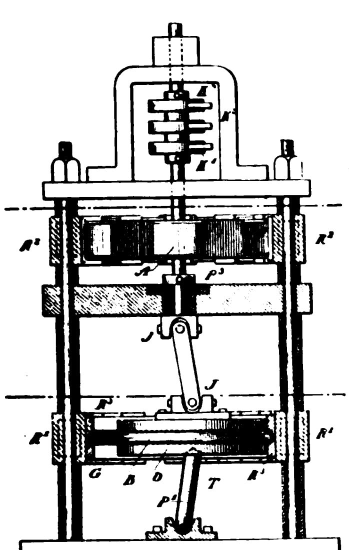

FIG. 2.

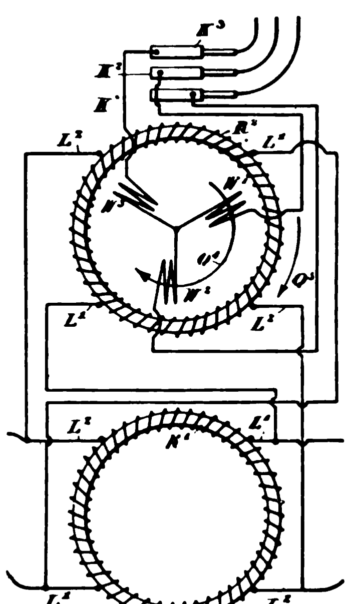

FIG. 5.

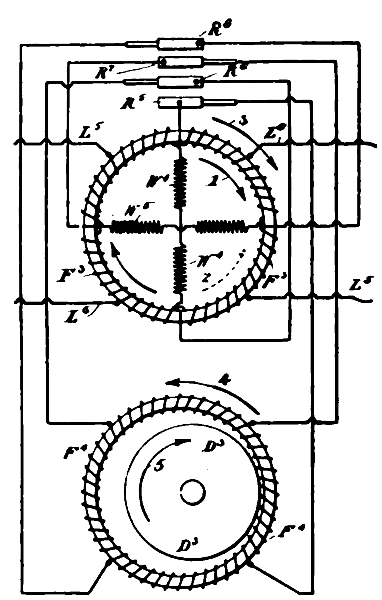

FIG. 6.

thickness as the ring, but having a diameter considerably less. It has a raised rib or flange, B, which fits into and travels in a track set in the ring, Fig. 3. This disc armature is pivoted, as shown, eccentrically to the field ring, with which it remains always in contact at one side of the inner periphery of the latter, and is supported by a spindle, P^1, which maintains the disc in stable equilibrium in any position it may assume within the ring. When the ring is energized, the magnetism attracts the iron disc, and, while holding it in firm contact against the ring at the side, it causes it at the same time to roll around the inside wall of the ring, following as it must the revolving polar line of the field. If, however, the rotating magnetism turns contra-clockwise, the disc in rolling the same way will revolve in a clockwise direction about its own axis, as indicated by the arrows in Fig. 3. Such is the motor part.

A universal joint, J, Fig. 2, serves the purpose of rectifying the eccentric movement of the disc, so that any apparatus carried by the upper spindle, P^3, will revolve concentrically with the upper ring, P^2, and this ring with its winding constitutes the primary or inducing element of the transformer, the three-coil armature, Figs. 2 and 4, with its three free ends connected to its three collector rings, Fig. 2, being the secondary element or induced circuit.

Such is the apparatus in its entirety, and it may be properly styled a motor transformer for voltage, phase and frequency, as all three functions can be performed as well simultaneously as one or two of them.

The essential peculiarity of the motor that adapts it to this use is the following: As the armature disc, D, has a smaller diameter than the ring inside which it rolls, so in rolling around the ring from a given starting point back to the same point again, the disc will have an entirely independent rate of rotation about its own axis, very different from that of the rotating magnetic field in which it turns, and which will be a function of the difference between the diameters of the disc and ring.

Here, then, we have the essential requirement of a frequency changing apparatus, the operation of which will be somewhat as follows: Fig. 5, being a diagram of circuits for reducing frequency. Biphase currents from the source of supply are introduced to the upper or transformer ring winding, the leads being so connected as to set up a clockwise rotating magnetic field in this ring. Naturally, the transformer armature would rotate in the same direction (if its circuits were closed) synchronously with the field, if free and unconstrained. If, however, the armature is not free, but is constrained to revolve at a slower rate, then multiphase currents (biphase in this instance) will be generated in its coils, having a frequency determined by the number of times the armature turns through the rotating magnetic field while the latter is making one revolution in space.

Let such constrained motion be assumed and consequent generation in the armature coils of multiphase currents, and let these currents be taken from the collecting rings and brushes thereon through leads down to the lower ring winding or motor field, the leads being so connected to this winding as to set up a contra-clockwise rotating field, or one opposite in direction to that of the transformer field above. This done, and the biphase currents from the source turned on, the motor disc will commence rolling around its ring in a contra-clockwise direction, but turning at the same time about its own axis in a clockwise direction, carrying the transformer armature with it in the direction of its own revolving field, as it would turn if free and unconstrained by the motor disc, but at a rate or speed of rotation identical with that of the

disc about its own axis, which is much slower than the speed of rotation of the transformer field—the latter having a rate corresponding to the frequency of the biphase currents supplied to it.

We, therefore, have in this transformer system a rotating magnetic field of comparatively high speed in the primary ring winding, and an enclosed secondary circuit revolving within the latter at a comparatively low speed in the same direction. Under these conditions the induced secondary currents of the armature will have a frequency due to the difference of these two rates of rotation. One of them, that of the field, is given, and the other is axial rotation of the disc—necessarily something less than that of its own motor field (when its diameter is more than half the diameter of the latter), and the latter identical with the frequency of transformed or induced currents in the armature coils. The disc acts as a sort of brake or load on the armature, holding its speed down below the synchronous rate, thus producing a slowly revolving motor field for the disc to roll in.

To increase frequency, a system of circuits like that shown in Fig. 6, will be found preferable. In this case, the biphase currents from the source of supply are introduced to both the transformer field and motor windings, and the connections are such that the transformer armature and disc will turn in a direction opposite to that of the field in which the armature revolves. In this case, as a matter of course, the induced secondary currents will have a frequency due to the sum of the two motions instead of their difference as before.

By having a variety of interchangeable motor discs of different diameters, a great variety of transformations can be made with the same machine.

TEST OF MAGNETIC CIRCUIT BREAKERS.—II.

BY C. M. CLARK AND C. W. MACMULLEN.

(Concluded.)

To make the tests on the circuit breakers, the resistance of the water barrel was adjusted so that only a certain overload of current could possibly flow in the circuit, even though the circuit breaker failed to open. The amount of the current was read by the ammeter. The switch A, was now opened, and the circuit breaker set. The revolving discs were brought up to the proper speed, and the revolutions counted. At the completion of the counting, the switch A, was closed, and the deflection of the galvanometer noted, the motor being then stopped. The radius of the circular arc made on the paper, was found, and its chord was carefully measured. This arc represents the time between the closing of the switch A, and the opening of the circuit by means of the circuit breaker. The apparatus and circuits were then examined and set again, and the experiment repeated. As is shown in the tables, three sets of five readings each, were taken with each setting of the instrument; the first with an overload not exceeding 50 per cent., the second with an overload not exceeding 75 per cent., and the third with as complete a short circuit as could be obtained, the greatest possible rise of the current, which was about two hundred amperes, being limited by the resistance of the wires and instruments.

Knowing the radius and the chord of the arc and the revolutions of the disc, the time was easily determined. Calibrations of the galvanometer were made from time to time, to see if the constants of its circuit had changed.

The mercury contact circuit breaker differs from the carbon contact circuit breaker in the following respects. It is of the "double pole" type, breaking both sides of the circuit. Instead of the knife contact arrangement used in the carbon contact circuit breaker four projecting metal lugs on the switch arm, two lugs at each end, descend into cups containing mercury. The insulation of the lugs is so arranged that when the circuit breaker is closed, continuity of the circuit is secured, and when the circuit breaker is opened, both sides of the circuit are broken. The switch arm is so balanced that the spring used in opening the other type of circuit breaker is dispensed with, the opening of the switch arm being aided by gravity.

Current rose to................ 7.8376 amperes.
Time factor.................... .1598 seconds.

Setting, 5 amperes. Current adjusted to short circuit.
Current rose to................ 59.67 amperes.
Time factor.................... .0812 seconds.

1. In this particular test the current rose slightly above 50 per cent. over load: which was due to a slight change in the E. M. F. of the dynamo, and also that the circuit breaker was somewhat sluggish in its action. All the tests were made under most practical conditions; following as nearly as possible the ordinary circumstances under which circuit-breakers are operated.

2. It will be noticed that at the setting of 75 per cent. over load the time was between three to four thousands of a second greater, this was due to a drop in voltage; resulting from heavy load on dynamo, causing the current to build up at a slower rate.

Setting, 6 amperes. Current adjustment not exceeding 50 per cent. overload.

Current rose to................ 62.27 amperes.
Time factor.................... .0548 seconds.

A comparison of the two forms of circuit breaker tested, i. e., the carbon-contact, and the mercury-contact circuit breakers, brings out some points of interest. The carbon-contact circuit breaker would seem to be better for general use. There is no troublesome arcing when the circuit is broken, and the moving parts are simple and effective. With proper care, the danger of corrosion is very slight, provided this type is used where there is not much dampness.

These circuit breakers have quite a high resistance, the one with a range of from 4 to 12 amperes having a resistance of .28 ohm (approx.), while the one having a range of from 15 to 40 amperes has a resistance of 0.5 ohm. Hence, the first consumes 2.52 volts and 22.68 watts, and the second 1.5 volts and 4.5 watts at working current, assuming these currents to be 9 and 30 amperes, respectively, or three-quarters of the maximum.

The mercury contact circuit breaker, in its present form, has the objection that it throws off mercury when operating. This kind of circuit breaker, is, by a slight jar, very apt to raise the contact points just out of the mercury, forming an arc and giving off very objectionable gases, besides spattering the mercury about. A slight jar may even throw them entirely out of contact, as they depend, to a greater or less extent, on gravity, to operate them. At the beginning, of the action, the inertia of the movable parts opposes the effort due to gravity. As the center of gravity changes, the motion is accelerated, but before this acceleration becomes appreciably large, objectionable arcing takes place.

In the operation of circuit breakers, for each setting, it would seem that the average current multiplied by the time would always equal a constant. This would be true if the operation of the circuit breaker depended only on magnetic action, but since in the majority of instruments, the solenoid serves only to release a spring which in its turn throws the switch arm and breaks the circuit, it follows that certain mechanical quantities must be introduced into the equation; and these quantities are not constants. In fact it is proper to divide the time required for a circuit breaker to open, into two parts, one being the time required for the current to supply the necessary electromagnetic energy and the other being the time of action of the mechanical elements of the apparatus. From the results obtained, it was found that the circuit breakers did follow, approximately, the law stated above.

LIQUID AIR AS A FACTOR IN ELECTRICAL DEVELOPMENT.

IN a communication appearing in the Boston "Herald," Prof. Elihu Thomson dwells upon some interesting considerations regarding liquid air as a possible factor in electrical development as follows:

The well known effect of cooling by liquid air or like gases, a conducting metal like copper, is to almost abolish its resistance. Consequently a conductor so cooled is able to carry very much larger currents with less loss than at ordinary temperatures. This fact has attracted the notice of electricians and physicists for a long time past. It has recently been found that liquid air is one of the most perfect insulators, and that most insulating materials cooled to the temperature of liquid air are greatly improved in insulating qualities. It is known, also, that cooling renders it more difficult to cause a spark to occur between oppositely electrified conductors, the striking distance for a given pressure being diminished.

The stability or permanence of liquid air in bulk, even when it is fully open to the ordinary atmosphere or kept at atmospheric pressures, is, of course, simply dependent upon the heat insulator provided, and if this could be made perfect the air would never evaporate.

Recent methods, such as those of Hampson and Linde, make it possible to obtain large supplies of liquid air by simple means and with moderate expenditure of power. Niagara power is 24-hour power, and as there are but few industries demanding power for the whole day it must follow that surplus power is either not used or wasted, and that to keep the plant working night and day at full capacity is desirable even if some of the power only yields a moderate return. Can it not be used in making liquid air? Cannot the excess at certain times of day be put to use in compressing air to be afterward liquefied on the large scale?

It would seem that large tanks of liquid air can be heat insulated very perfectly by layers of air and fibrous material properly placed outside. The evaporated air from the tank could traverse the jacketings in successive order from within outward so as to help keep down the temperature of the jacketings. A furnace with an internal temperature of 2,000 degrees to 3,000 degrees above the normal temperature of the air is easily insulated by moderate thicknesses of asbestos or other fibrous coatings so that the outside temperature is but slightly above the normal.

The temperature difference between liquid air and normal air is, say, ⅛ of that between the interior of the furnace assumed and the normal, so that it ought to be possible to insulate so that but little heat would enter. In most electric long distance transmission lines, a loss on the line of about 10 per cent. to 15 per cent. is suffered. With 10,000 horse-power this would mean from 1,000 to 1,500 horse-power lost in resistance of line. If the conductors were immersed in a pipe with liquid air the loss might fall to not over 1 to 2 per cent. perhaps, leaving available a range power for condensing air to supply evaporation.

Just how far 1,000 horse-power would go in keeping the conductors supplied with liquid air coatings is a matter requiring data to determine. But if it were not sufficient for the purpose there is the surplus of power during certain hours to supplement it.

But it may be possible that a much higher voltage than is now used (10,000 to 20,000 volts) may be successfully used with conductors cooled and insulated by liquid air. If the potential could be raised to 50,000 volts, either the loss on the conductors for a given power transmitted would fall off as the inverse square of the voltage, as the conductors could be made smaller in the same proportion or the distance of transmission increased with the same section of conductors as the square of the potential.

These are matters worthy of experimental determination. The limit to the capacity of an electric transformer to transfer energy from its primary to its secondary circuit is found in the heating and loss involved in the copper conductors comprising these circuits, and upon the nearness with which the two circuits may be placed one to the other, which is in turn governed by the insulating material used to separate them. Could the conductors be kept cool by liquid air, and thereby their conductivity and insulation greatly increased, the work of transfer in a transformer could be much greater for a given size than it now is, or the loss could be made even less than it now is, although but 3 per cent. is sacrificed in ordinary practice.

Transformers in liquid air might be made entirely of copper

without iron, and their light load efficiency become nearly equal to full load efficiency. A transformer without iron would avoid the loss in the air, and would permit such a saving in material that changes in design or disposition of the copper could be made to suit the condition of absence of the iron.

We need not touch upon the possibilities of liquid air as a means of energy storage, for they are self-evident enough, since liquid air is virtually compressed air, which remains compressed, as it were, even when exposed to atmospheric pressure; that is, addition of heat gives to it pressure and the ability to do work in suitable engines as in the usual compressed air motors. Our object has been to briefly point out what may be termed possibilities in electric engineering, assuming that data favorable to the ideas presented be the outcome of experimentation.

It is too early to make any predictions or calculations concerning this subject. It must be confessed that it has a certain fascination. Perfection of heat insulation seems to be the key to the situation. All else seems to depend on that, the main questions being what will it cost in power and machinery to supply the necessary evaporation waste in a system of the kind outlined, and whether the voltage of transmission can be raised in consequence of the new conditions.

LUMINOUS RADIATIONS FROM THE HUMAN BODY.

At the Société de Biologie, at Paris, Dr. Luys read a paper describing experiments made by him, showing the presence of luminous emanations which surround the human body, and he demonstrated it in the following manner. In the dark room, place your fingers for about 20 minutes on an ordinary photographic plate which is itself in a bath containing the usual solution of hydro-quinone, and after this exposure fix the negative in the usual way. You will see not only your fingers and the lines on the skin reproduced, but also their pores, and, what is still more interesting, round the fingers a sort of zone or halo a third of an inch wide, which would lead one to believe that we live in a luminous fluid, which has enabled us to obtain a photographic print of itself and of the fingers, as if under the influence of light. Dr. Luys has tried the same experiment, but without any results, on patients whose hands were paralysed, benumbed, or insensible to touch. No image appeared on the plate.

ELECTRIC LIGHTING

THE SHOREDITCH, ENG., REFUSE DESTRUCTOR AND ELECTRIC WORKS.

TOWARD the end of last month the Vestry of Shoreditch, London, celebrated the completion of its electric light and refuse destructor plant, the switching on of the current being done by Lord Kelvin.

The Buildings.—The buildings consist of a destructor house and engine house, as well as suitable offices for the new department. The engine house is 68 feet long and 46 feet broad, and is shown in Figs. 1 and 2. It is arranged with the high-tension continuous current steam dynamos on one side, and the low-tension sets and station motor transformers on the other side. A gallery of ample width is provided against one wall of the engine house to accommodate the three switchboards. Adjoining the engine room is the test room, in which will be erected all the testing instruments, and which, in addition, will be used for the calibration of meters. The offices, which front on to the street at the end of the engine room, contain suitable accommodation for the Electric Lighting Committee to hold their meetings, for the engineers and for ordinary office purposes. In order to prevent, as far as possible, vibration from the running of the engines, the whole floor of the engine house has been made a solid mass of concrete, about 10 feet in thickness, and the surface of this has been tiled over in a neat manner. The destructor house is a building 80 feet by 80 feet, with a roof of unusual shape and dimensions. It forms a portion of the covering for the sides of the buildings in place of carrying the brick walls right up to the usual heights. (See Fig. 3.) There are also provided bathrooms, both for the engineers and the men, and accommodation for the men for taking their meals, etc.

Refuse Destructors and Boilers.—The refuse destructors and the steam raising plant are so interconnected in this installation that it is impossible to describe the one without

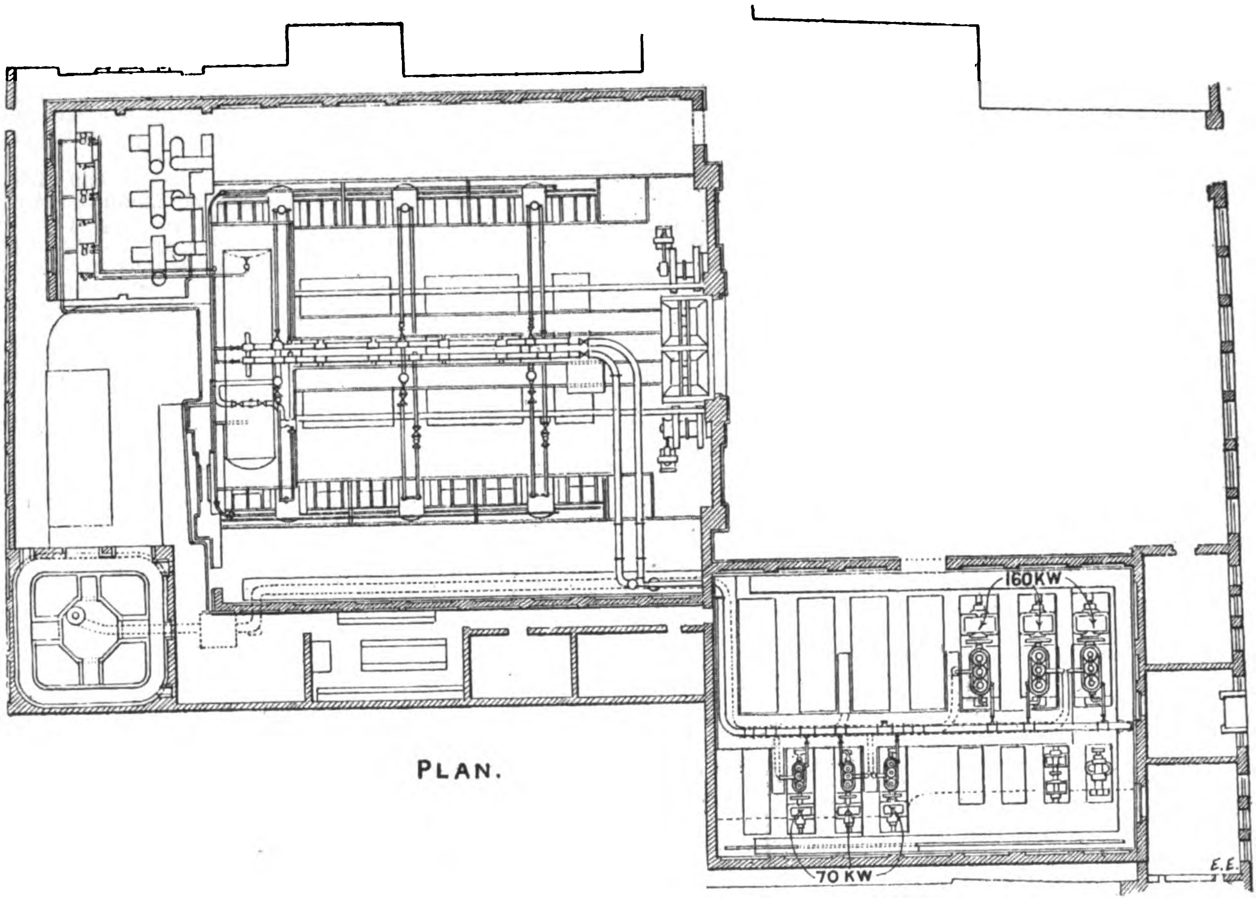

Fig. 1.—Shoreditch, England, Electricity Works and Refuse Destructor.—Plan.

the other. This part of the work was executed by Messrs. Manlove, Alliot & Co., who in 1893 reported to the Vestry as to what results they could guarantee in the way of heat for electric lighting purposes by the burning of 20,000 tons of dust per annum. This firm reported that with the aid of the thermal storage system of Mr. Druitt Halpin such refuse would produce sufficient heat for the electric lighting station proposed by Mr. Manville, the consulting engineer, and they pointed out that the value of the steam so produced would be £4,290 per annum, and that a saving of at least £1,500 would be effected by burning the dust instead of disposing of it by barging.

The destructor house contains 12 cells for burning refuse, and 6 Babcock boilers, which are placed each between two destructor cells. The chimney is 150 feet high and 7 feet internal diameter at the top. It is lined with firebrick throughout. At the base a centrifugal dust-separating chamber has been constructed. The cap of the shaft is of cast iron put together in segments. The cells are worked under forced draught supplied from the fans placed in the adjoining shed. These fans are driven by motors on the fan axis, and are each capable of delivering 8,000 cubic feet of air per minute against a pressure in the ashpits equivalent to 3 inches of water. Steam jets are also provided to increase the draught should occasion require.

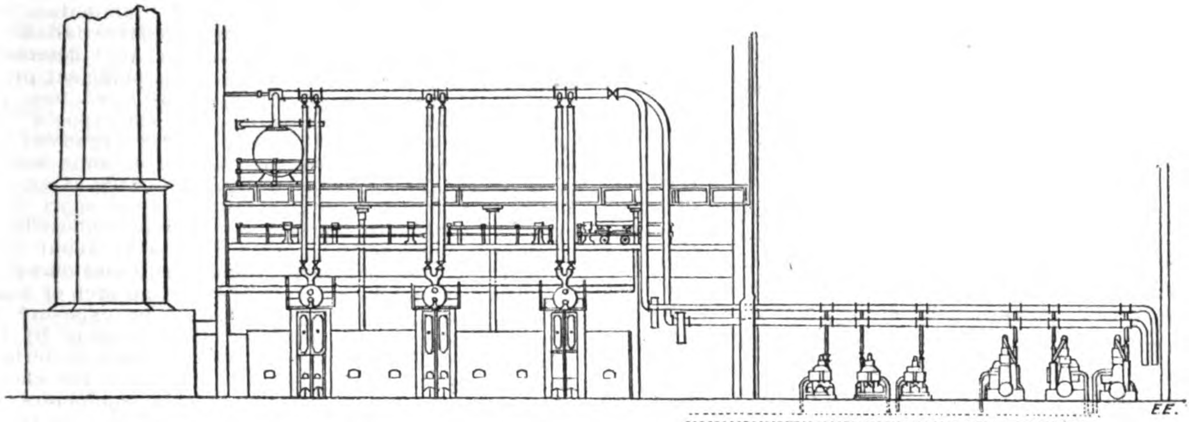

FIG. 2.—SHOREDITCH, ENGLAND, ELECTRICITY WORKS AND REFUSE DESTRUCTOR.—LONGITUDINAL ELEVATION.

The gases pass from the destructor cell directly to the space above the fire bars of the boiler. The openings in the firebrick seating are near the front, so that the hottest part of the cell delivers direct into the boiler. Also, as the green refuse is higher up on the sloping grate, any noxious fumes distilled off by the temperature rising are drawn down over the hottest part of the fire and cremated. Wherever required, each boiler may be shut off entirely, by means of dampers, from each or both of its adjacent cells. It may also be fired at all times with coal or any other suitable fuel, or independently at times of heavy load, as the ordinary fire bars are provided under the boiler. Again, the cells may be worked independently of the boilers, but in this latter contingency the gases pass out from the cells at the back and not at the front. Owing to this arrangement, the cells may be repaired independently of the boilers, and the boilers may be repaired independently of the cells; moreover, in the event of refuse not being collected or being deficient from any cause whatsoever, steam may still be raised by means of coal in the same manner as is adopted in any other electric lighting boiler house.

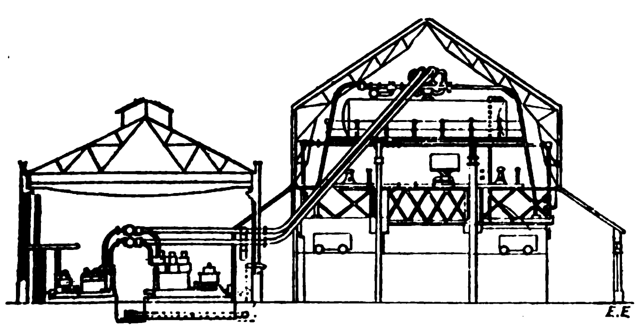

FIG. 3.

The cells have each a grate area of 25 square feet, and the boilers have each 1,300 square feet of heating surface. The flues are arranged in duplicate to facilitate cleaning, as one flue can keep the whole station going.

The cells themselves are not charged with refuse by hand, but by means of Boulnois and Brodie's patent charging trucks. This arrangement is novel as arranged at Shoreditch, although the principle has been adopted in many other district stations. This arrangement and the gear for handling the refuse are worthy of special note. At one end of the destructor house two electric elevators have been erected to hoist the refuse to the tipping platform. The dust carts discharge their loads into large hoppers, mounted on electric bogies, which are placed on the elevators. When the hopper is full, it is elevated to the level of the tipping platform. There two electrical connections are made to two trolleys running on overhead wires. On the circuit being closed the motor on the bogie moves the hopper along the rails, until it has reached the required position. If the refuse is required for immediate use, it is shot outward by tipping the hopper as the two rows of openings on each side of the central bins discharge direct into the charging trucks. The central row of openings lead to the storage bins, where a certain amount of refuse can be kept till wanted. That this is a necessary provision will be understood when it is remembered that the dust carts collect during the day time only, while the destructor will cremate the refuse at a regular rate throughout the twenty-four hours. The two electric lifts are worked by one motor, which is geared to the hoisting drum by means of a worm and wheel running in oil.

The remaining feature of the destructor scheme is the use of Mr. Druitt Halpin's thermal storage system. At present one cylinder, 35 feet long and 8 feet diameter, has been installed, and is supported on the girders, shown in Fig. 3. Steam will be generated in the boiler at all hours, owing to the necessity of burning refuse continuously, and hence the working conditions are essentially different from those prevailing in the ordinary coal-fired boiler house. On the other hand, light being required on a large scale only during some four to six hours out of the twenty-four, it is obvious that without some system of heat storage a vast amount of valuable steam would be wasted. With the arrangements at Shoreditch, during the day time, steam generated in the boilers will be passed into a thermal storage cylinder, where it will be mixed with a small quantity of cold water from the feed pumps, the proportions being such that when the evening approaches, the cylinder will be full of water at the temperature and pressure of the steam required by the engines. The cylinder will then be shut off from the feed pumps and connected to the boilers, which in their turn are connected direct to the engines; hence, when the boilers require feed water, they are supplied with it from the cylinder at such a temperature that the fuel that is then being burnt has merely to furnish to the water in the boilers the heat sufficient to overcome the latent heat of evaporation at the required pressure. The result of this arrangement is that the boilers are able to evaporate about one-third more steam than they would be able to evaporate were they fed direct. The importance of the thermal storage cylinder is further enhanced by the fact that it acts as a water purifier, as in it the deposit will be thrown down instead of in the boilers. When more storage cylinders have been added, steam will also be drawn from the thermal storage, but at present it will be used as a feed storage only.

THE ELECTRICAL PLANT.—There are two systems of electrical generation and distribution used at the Shoreditch station. One of these is a low tension system of 150 to 165 volts for supplying consumers in the immediate vicinity of the

station and the other is what is known in England as the "Oxford" system, named so after the place in which it was first employed. This latter system furnishes current for the outlying districts at 1,000 to 1,1000 volts. These high tension circuits are led to substations where rotary transformers are situated which convert the current to a potential of 165 volts for general distribution. At these substations storage batteries are installed.

The system of charging adopted for current for lighting purposes is the Wright demand indicator system, 6d. per unit being charged for an average daily use for two hours of each lamp demanded through each half-year, and 4d. per unit for electricity consumed beyond that average two hours' consumption. In addition, there are two rates of charging for current used for motive power purposes—namely, 3d. per unit for current which may be demanded at all times of the day and night, and 2d. per unit for current that may be demanded during the hours of daylight.

THE INCONSISTENCY OF PLAIN IRON INTERIOR CONDUITS.

BY "JIM CROW."

IN these days of rapid progress and constant individual effort to outstrip one another in the production of novel ideas and applications, it seems advisable to pause occasionally for the purpose of reviewing what has been done in the past and considering the possible effect of new methods on practices that have heretofore been attended with success.

Some electrical engineers have apparently neglected such precautionary consideration, however, in their efforts to introduce the use of plain iron pipe as an interior electrical conduit; and while an individual may readily be excused if he is a little over zealous in the exploitation of his pet scheme, it would seem that a reasonable degree of conservatism should be expected from Departments of Inspection which make and enforce wiring rules that govern electrical workmen throughout the entire country.

For a number of years the art of electrical wiring has progressed along lines of safe construction and high insulation; and on these lines electrical men have put forth an incalculable amount of energy in creating and codifying rules which have the one word "INSULATION" as their sole foundation. These rules require, among other things, that conductors of low tension currents when placed inside of a building must be covered with rubber insulation at least 3-64th of an inch in thickness. They must be kept free from contact with gas, water, or other metallic pipes. They must be protected when passing through floors, partitions, etc., by tubes of glass, porcelain or other such material. They must be kept apart at least 2½ inches. And they must be supported wholly on incombustible insulators.

These are a few of the requirements for so-called open construction, where the conductors are surrounded by air except at the points of contact with the porcelain or glass insulators placed about 4 or 5 feet apart; while it is proposed by the advocates of plain iron conduits to place conductors connected to the same circuit in other parts of the building, side by side, in a plain iron pipe, which is grounded all along the line.

A peculiar result of this plain pipe rule and its contradictions is shown by the recently published specifications of an electrical engineer of national reputation who calmly requires that "all conductors be installed in plain iron pipe," and that "all fixtures be provided with insulating joints of the latest and most improved design," etc. Surely there is some slight inconsistency in such rulings and their results; and the average lay property owner can scarcely be blamed if he concludes that quite a large percentage of electrical rule makers and engineers are eligible candidates for a sanitarium.

There is something truly pathetic in a proposition which embodies plain iron pipe and insulating joints in one installation; and, while the first impulse is to give way to the ludicrous aspect which is presented, when the erroneous position is realized in all its enormous proportions, feelings of merriment are quickly dispelled by the most deep-seated regret for the years of labor, the incalculable amount of capital and the number of human lives that have been sacrificed in order to demonstrate the necessity of high standards of insulation, with no result other than the proposition to go back of the beginning and install conductors in plain iron pipe mainly for the purpose of reducing the cost of installation.

One of the excuses given for the use of uninsulated conduit is that combination gas and electrical fixtures have always been of uninsulated pipe and have contained many miles of electrical circuits; but most engineers will acknowledge that these electroliers have almost invariably been provided with insulating joints offering resistance of from 1,000 to 5,000 megohms, and even with this precaution about 90 per cent. of the trouble which has been experienced in conduit systems has been developed in the unlined fixture stems.

Many people object to the use of insulated iron-armored conduits, for the reason that in past years the insulating lining has not come up to their expectations, inasmuch as it has softened and cracked under high temperatures. But this can scarcely be considered as a valid excuse for rejecting entirely the use of insulated conduits, unless the man who, upon discovering an error in the indications of his meter, is to be excused for denouncing all systems of illumination other than the good old-fashioned and always reliable tallow candle.

If 3-64th of an inch of soft rubber, that deteriorates rapidly by exposure to the atmosphere, is sufficient protection to conductors laid in a grounded, uninsulated iron pipe, it is equally sufficient for conductors that are exposed their entire length. Therefore, on the same line of argument the owner of a building who purchases marble or slate switchboards, switch and cut-out bases and panel boards at an expense of $1,000 to $1,500 in a large building is little short of a lunatic, when he could just as well have his switchboards and other appliances made of cast iron frames at about 2½ cents a pound, and from which he could easily and cheaply insulate his switches and cut-outs by 3-64th of an inch of hard rubber, which would not readily deteriorate by exposure to the atmosphere and which could be made fireproof by being covered with a sheet of asbestos or other such material; and the man who bought unsightly and expensive porcelain or glass insulators on which to support his conductors would be guilty of a most reckless extravagance, for he could just as well use cheap cast iron knobs of an ornamental and attractive design, or double pointed tacks which would be still cheaper.

With the plain iron pipe rule for concealed work in force, Inspection Departments must, in order to be consistent, withdraw their requirements for the expensive high class insulation required by existing rules for open construction. But it does not seem possible that such highly intelligent men as those at the head of the Inspection Bureaus of this country can deliberately take such a long step backward; and it is doubtful if these men are willing to admit—as a plain pipe rule would imply—that they are unable or unwilling to find a satisfactory method of insulation, or that they are unable to comprehend insulation beyond that provided by 3-64th of an inch of soft rubber; nor is it probable that the manufacturers of America are unable to produce any higher insulation. There are now on the market interior insulated conduits that are practically unaffected by any degree of heat or moisture to which they can possibly be submitted in service; and such conduits can be obtained for less cost than those found on the market two years ago.

This subject was more or less aired in one of our electrical journals last spring; and, although the number of the articles printed was not large, their tenor did not indicate, as was assumed in the summing up, a "preponderance of opinion in favor of plain iron pipe," as the following figures will show: Of the whole number of letters printed nearly 42 per cent. were absolutely in favor of insulated- iron armored conduit; fully 19 per cent. were in favor of an enameled conduit, making a total of 61 per cent. in favor of an insulated conduit; while 30.5 per cent. were in favor of plain iron pipe, and the remaining 8.5 per cent. were written by three men, one of whom declined to express an opinion, another believed in plain iron pipe, but admitted that his opinion was of no value, for the reason that he had had no experience to justify his belief, while the third failed to express much of anything except a burning desire to revolutionize the present system of inspection. It would, therefore, appear that in the absence of any overwhelming demand for such a radical departure from former teachings, it might be well for Inspection Departments to consider carefully the promulgation of new rules, which, if enforced, will be, to say the least, inconsistent not only with their own requirements, but also with the common-sense rules of good, safe construction.

TARPON SPRINGS, FLA., QUITS.

At a special freeholders election at Tarpon Springs, Fla., it was voted to discontinue the lighting of the streets. The electric plant of the Tarpon Springs Electric Light and Water Company, A. P. Weller, manager, has been moved to St. Petersburg, Fla., and will be in operation August 1.

ALTERNATING ARC LAMPS IN CONNECTION WITH CONDENSERS.

In an interesting communication appearing in our esteemed contemporary, "l'Industries Electrique," M. Georges Claude puts forth a strong claim for the employment of condensers in connection with alternating arc lamps, whose unsteady action, he asserts, can be entirely obviated by the use of condensers. He bases his claims on the statement that if alternating current arc lamps act badly the cause thereof is due largely in the increase of the apparent resistance of the regulating magnet which accompanies the sucking in of the magnet core. In order that these lamps may approach to the conditions existing in continuous current lamps all that is necessary is to make arrangements for keeping this resistance constant.

It will be further apparent that the ideal conditions would be realized if we could so arrange matters that the resistance diminishes when the core is sucked in, for in that case the current would vary faster than the difference of potential, and we would thus reach even more favorable conditions than in the case of the continuous current.

In order to verify his theory M. Claude made experiments on an arrangement similar to that illustrated diagrammatically in Fig. 1, in which a condenser is shown in series with a shunt magnet around the arc. These trials show that the current varies in fact twice as fast as the difference of potential, and, again, that it varies scarcely 1-5th as fast when the shunt magnet alone is in series, without the condenser. It will be evident that under these conditions the least variation in the distances between the carbon is followed by a considerable variation in the attraction, and that therefore a lamp thus modified is in an infinitely better condition of regulation.

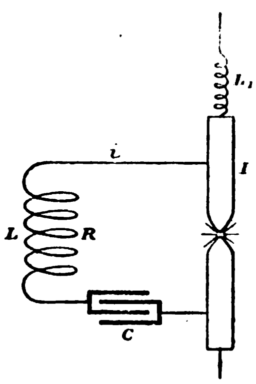

FIG. 1.—ALTERNATING ARC LAMP WITH CONDENSER.

It must be remarked, however, that suitable precautions ought to be taken to avoid a source of instability brought about by the very efficiency of the condenser. Supposing, in effect, the core to be in equilibrium in a certain condition; now if the core for any reason is sucked in a little deeper, by the very fact of this displacement it will permit of a greater current passing through the coil, and it may happen that it may continue its movement to the end of its limit. But it is evident that it would suffice to avoid this trouble to employ an antagonistic force of sufficient variable rapidity.

The condenser necessary for this work need be constructed to resist a potential of only thirty or forty volts existing at the terminal of the lamp, raised, perhaps, to fifty or sixty volts by resonance effects. Under these conditions the thickness of the dielectric in the condenser need be but very thin.

On the other hand, this arrangement will necessarily lead to very fine coils in the lamp, having high self-induction, and thus at high frequency requiring but very small capacity for their neutralization. In practice only very small condensers would be required, consisting of a disc 10 centimetres (4 inches) in diameter and a thickness of 3 centimetres (1.2 inches). Such a condenser could be easily lodged in the lamp case, and would cost very little.

CARBIDE OF CALCIUM has been found to be a remedy against the phylloxera, according to a Swiss trade journal, and to be also an excellent fertilizer for plants of all kinds.

ALTERNATE CURRENT DYNAMOS IN PARALLEL.

BY LAMAR LYNDON, Kobe, Japan.

In your issue of May 5, Mr. J. E. Woodbridge, in concluding his clear and instructive article on "Alternate Current Dynamos in Parallel," says:

"The ideal governing arrangement (and an easily attainable ideal) for a set of engines or turbines, each driving one of a multiplied set of alternators, is a single governor controlling, through connected mechanism, the point of cut-off, gate opening or gas admission, as the case might be, of all the power units. Such a mechanism would, for example, keep the cut-off in each of a group of engines at the same point. All engines of the same size in the group would then be exerting at any load the same power, and engines of different sizes would be exerting powers proportional to the sizes of their cylinders."

I wish to call attention to the fact (probably well known to Mr. Woodbridge, but overlooked by him), that while with a governor of the kind mentioned, the I. H. P. of the various engines would be strictly proportional to the areas of their respective cylinders, it does not necessarily follow that the brake or effective horse-power would be.

The assumption that there would be no acceleration or retardation of any engine in the group controlled by a single governor, actuating the cut-off of each, could only be true, if the mechanical efficiencies of these engines were equal. Now, it is a well known fact that the ratio of brake to indicated horse-power, even in identical engines, is never the same, except, perhaps, when they are first installed, and, indeed, the mechanical efficiency of the same engine varies with conditions of wear, lubrication, condition of valves and piston, and (most of all) packing.

For this reason, it is plain that engines giving indicated horse-powers proportional to their cylinder areas, will usually give brake horse-powers that are in no wise so proportional, and as it is the brake horse-power that determines the acceleration or retardation under load, the method of regulation proposed will hardly give the desired result.

As a matter of fact, instances have come under my observation in which the $\frac{\text{b. h. p.}}{\text{i. h. p.}}$ has varied as much as 8 per cent. in the same engine, and I have seen small engines actually slowed down by tight packing.

Of course, with extreme care in construction and operation, it might be possible to make the mechanical losses of each unit proportional to its cylinder area, but I doubt if this could be effected in continuous practice.

LIGHTING PLANS OF A CHICAGO IMPROVEMENT ASSOCIATION.

At a meeting held at the Wellington Hotel, Chicago, the organization of the Wabash Avenue Improvement Association was effected, comprising merchants and business men on Wabash avenue, two from each block between Lake and Harrison streets.

The objects of the Association are to originate, discuss, and put into execution all plans and projects that will contribute to the improvement of Wabash avenue for business purposes. The plan at the outset which suggested itself as being of primary importance was that of securing adequate lighting for the street at night by the installation of an average of ten arc lamps to each block between Lake and Harrison streets by private subscription. These arc lamps are to be hung out in front of the places of business at a point designated by each subscriber. The only uniformity sought to be preserved will be the distance in which the lamps are to be hung from the frontage of the buildings and the pavement. Other schemes for the improvement of the avenue have already been broached and the general prospects of the street as a business thoroughfare are much brighter than they have been for some time past. The lamps which are to be used will be the five ampere, low tension, single enclosed arc type and will be hung on a wrought iron ornamental bracket of peculiar design. A specimen arc lamp submitted by the Chicago Edison Company was on exhibition during the second meeting of the association.

Vol. XXIV. NEW YORK, JULY 22, 1897. No. 481.

ELECTRICITY FROM GARBAGE.

ONE of the problems which confront municipalities of every size and description is the disposal of garbage. Where towns are located near the ocean or in proximity to large bodies of inland waters the usual bad practice is to load the offal on barges, tow it out several miles from land and dump it. Most of it probably goes to the bottom, but enough keeps afloat to find its way ashore, as the disgusted and nauseated bathers at Coney Island and on the New Jersey coast can vouch for. In Chicago the practice of dumping garbage into the source of the city's water supply, Lake Michigan, has given rise to such epidemics of typhoid fever that the intake for the water mains has recently been pushed out again several miles further into the lake. Where no such large bodies of water exist, the only alternative is to dump the foul mass at some presumably safe distance from the inhabited locality, filling up "flats," where it rots and festers indefinitely. As time passes and the electric railway reaches out its arms, these filled in "flats" become the building lots of the real estate speculator and the inhabitants of dwellings erected on them are constantly subject to the noxious emanations from the made ground on which they live. All this is an old story, yet no attempt worth mentioning has been made in this country to remedy this state of affairs. In strong contrast to our own supineness on this subject, and perhaps because of the greater pressure of the necessity, are the efforts making in England to solve this question in a satisfactory and at the same time economical manner. The cremation of garbage in so-called dust destructors has now been introduced in a number of English communities with apparent success, but what is more to the point, is the utilization of the heat value of this waste product for the generation of steam for driving electric light engines. The latest example of this class of installation is that erected by the Shoreditch Vestry, London, which is described and illustrated elsewhere in this issue. Perhaps the most salient feature of this installation is the employment of the Halpin thermal storage system. This leaves the work of the boilers practically independent of the load on the station and permits of a continuous disposal of the garbage.

The example before us leads us to believe that in this direction many of our own electric light and power companies may find a way to increase their profits with a comparatively small original expenditure. It may be taken for granted that any municipality would welcome a proposition that would relieve it wholly or in part of the expense of carting or dumping the city garbage several miles off; it might even be, and usually is, willing to pay something to be relieved of the trouble and expense. Even granting the low calorific value of garbage as a fuel, the abundance of the supply and the absence of cost to the company would make its use under the boiler just that much clear profit. But it seems to us that, aside from the purely economical side of the question, there is another which is well worth considering in these days of municipal ownership agitation. We may be mistaken, but we believe that an electric light company that would offer to receive and cremate or "render" all, or a part, of a city's garbage, would raise a host of friends in that community, on whom the corporate property destroyer would make little impression. Thus from several points of view it appears worth while for American electric light companies to look into the garbage fuel question, or to consider the matter of going into the garbage rendering business, where it can be done without offending the nostrils of the neighborhood. The tentative efforts made in this direction by many of our American communities attest the need of some systematic dealing with the problem, for our cities are growing rapidly, while notions of economy and of the value of refuse forbid longer resort to the barbaric methods of old.

THE COST OF STEAM POWER.

THE cost of steam power is now more than ever the subject of anxious study among power users, and electric station operators are eager for any light that can be shed on the matter. But it seems that it will take some time to reconcile the varying figures presented. One of the most remarkable statements which we have recently seen is that of Mr. Frank P. Sheldon, mill engineer of Providence, R. I., who has been investigating the question of cheap fuels in New England, and who communicates some interesting figures to the Engineering Record regarding the cost of power in New England textile mills; the figures, it is stated, being obtained from the actual accounts for a year's time, kept by the mill owners. The engines used were compound condensing with steam pressures from 125 to 130 pounds. The engines were of from 1,000 to 1,200 h. p., working against a steady load 10 hours a day for 307 days per year. Mr. Sheldon gives in the following table the highest and lowest cost per h. p. per year, among several plants examined.

	Lowest.	Highest.
Fuel	$4.76	$6.60
Labor	2.34	2.71
Supplies	.31	.51
Repairs	.19	.31
Total running expenses	$7.60	$10.13
Fixed charge	4.04	4.72
Total cost per horse-power per year	$11.64	$14.85

The fixed charges include taxes, interest at 5 per cent., insurance and depreciation at 5 per cent. The large difference, according to Mr. Sheldon, is chiefly due to the cost of fuel, which in the first or lowest plant cost $1.76 per ton of 2,240 pounds, and in the second, or highest, $3 per ton.

These are most astounding figures when compared with others which have gone on record from accepted authorities. Even Dr. C. E. Emery, who will certainly not be accused of having ulterior designs against the perpetuation of steam as a motive power, never approached the rosy figures of Mr. Sheldon. As it happens, Dr. Emery in a paper read before the American Institute of Electrical Engineers in 1893 gives the results of a very comprehensive study of this question of costs, involving conditions almost identical with those encountered by Mr. Sheldon. Thus, Dr. Emery's figure for a 500 h. p. plant running 308 days of 10 hours each per year, with coal at $2 per ton of 2,240 pounds, with compound condensing engines, is $21.97 or nearly $22 per h. p. per annum; while with coal at $3 per ton the cost was $25.53 per h. p. per annum. Making due allowances for the difference in the size of plant in the two cases the difference is still far beyond what could be explained in this way. To go more into detail, we find that where Mr. Sheldon gives as the cost of coal for the $3 per ton plant as $6.60 per annum, Mr. Emery cites $10.69. Dr. Emery allows 5 per cent. more for interest, depreciation, etc., than does Mr. Sheldon, but even this increased figure fails to account for the great gap yawning between them. The statement that steam power can be produced in New England for $11.64 per annum must sound queer to those who have established themselves at Niagara Falls. However, we do not think they need have any regrets; but for the interest and benefit of the entire industry of the country Mr. Sheldon ought to give a further detailed statement, showing how he arrived at his extraordinary results.

LAMENTATIONS FROM LAKEWOOD.

THE following pathetic little item appears in the Cleveland Press of July 12:—

"Lakewood's electric light plant was not started on July 4, as promised by the hamlet officials. As a result the citizens are up in arms. They are roundly censuring the trustees, who, they claim, are responsible. The hamlet was never darker. Its streets are lined with trees, which keep out the light from the stars and moon. An indignation meeting is being strongly advocated."

We have made a few inquiries on the subject and learn that, as suspected, this is another of the many municipal plants that have gone wrong. The hamlet of Lakewood is a suburb of the city of Cleveland, to the westward. Some time last Fall, the people authorized the issue of bonds to the extent of $20,000 for the purpose of providing a plant to furnish them with a certain number of arc lights for their streets and incandescent lighting for their houses. An agreement was made by the hamlet with a contractor to erect the plant, but last April he threw up the job. Since that time, the hamlet has been trying to get the security company that was on the contractor's bond to go ahead with the work, but that plan has not succeeded. The condition of affairs was thus graphically described in one of the local papers last May:—

"Festoons of electric wires, several rows of poles and a partially completed dynamo and power shed, constitute the present Lakewood electric light plant. The claim is made that nearly all the work will have to be done over. It is alleged that the wires are not properly attached to the poles, some of the complainants going so far as to declare that they are only wrapped around the cross-beams. When the plant was begun, it was given out that electric lights would be burning in Lakewood by the middle of April. The poles were raised in the middle of Winter. Some of them are already toppling. They are crooked and ungainly. Mayor Tyler is severely criticised for permitting such a state of affairs. No attempt, is is claimed, has been made to have the plant completed. Meanwhile, the wires are rusting on the poles."

Meantime, the hamlet is paying interest on its $20,000 of bonds, has no light, and is without prospect of getting any.

CONFIDENCE IN STREET RAILWAYS.

THE attitude of investors at the present time toward street railway enterprises must be regarded both as a sign of better times and as a proof of the confidence felt in that particular form of investment. The Metropolitan Road in this city has just offered $2,000,000 for subscription in 5 per cent. gold bonds, and the public came forward so readily to take it up that the subscriptions reached more than $50,000,000; in other words, the issue was asked for twenty-five times over. Not long ago such a mark of confidence and better feeling would have been simply impossible. We note also that the issue of the $4,000,000 of bonds, 5 per cent., at 97½, and accrued interest, of United Traction Co., of Pittsburg, were also subscribed last week more than twice over. The New York Metropolitan bonds which were offered at 105 have been selling in the open market at 110½.

The trade figures in favor of this country are certainly not the least remarkable of the conditions pointing to improvement. The exports for the fiscal year ending June 30 are the largest in the history of the country by $21,700,000, reaching a total of $1,051,987,091, and exceeding the imports for the year by the very respectable amount of $287,613,186. No man would be regarded as going rapidly to the dogs whose farming or whose bank account stood that way. Moreover, aside from our advantageous trading of the past year, there is abundant proof that this year, with wheat up about 20 cents, this country is the only one with an average crop, of which a large proportion will be required for export at advancing prices.

It is curious that at this juncture when bank reserves are generally so far above the legal ratio, and when gold seems more likely to come flowing into the country than to be leaving it, such enormous finds of the precious metal should be reported from the far Northwest, both within our own borders and the Dominion. In fact, Canada looks to us as on the verge of a gold mining boom that is likely to throw even Transvaal and Californian records into the shade. Out of these, and other conditions, there can be but one outcome, at no great distance of time, and that is, distinctly better business everywhere. Out West it has certainly begun.

THE FAILURE OF GERRYCIDE.

IT will be remembered that gerrycide, or electrocution, was introduced a few years ago, with a great flourish of trumpets, as being the best means of inflicting the death penalty and as being destined by its mysterious nature to lessen the number of murders. The New York Superintendent of State Prisons has completed the collection of statistics showing the number of executions for murder that have taken place within the State of New York since its creation as a State. The result shows a remarkable increase in the number of executions since the killing by electricity began in 1890. Since that time forty executions have taken place, while from the creation of the State until that date there were but 230 hangings, as far as the Prison Department has been able to learn from the statistics gathered from all the counties. This shows an increase of more than 200 per cent. a year, as compared with the number during the preceding 100 years.

Mr. C. N. Baker, chief clerk in the Prison Department, remarks that the increase was most surprising, and in his opinion is due to either one or both of two conditions, viz.: that juries, believing in the humanity of the present system of execution, are more liable to convict; and that, the place of execution being removed from the county where the criminal is known, there is less likelihood of successful efforts being made for executive clemency.

For our own part, we regard gerrycide as a very uncertain and very brutal means of killing anything or anybody; but whether it be humane or cruel it has at least had the effect, or is attended by the result, of a seriously abnormal increase in the number of murders. Once more we venture to move for the repeal of Mr. Gerry's law.

PROF. ALFRED M. MAYER.

IN the death of Prof. Alfred M. Mayer, American science has lost one of its brightest and noblest lights. Though perhaps less well known to the present generation than to the student of twenty years ago, his writings and lectures in his chosen fields will always stand as models of precision and clearness of expression. It was no mean tribute which Joseph Henry bestowed upon the youthful Mayer when he called him his son in science; for there have been too few, unfortunately, among American scientists who, like Henry and Mayer, have cultivated science for science's sake alone, and have stuck to their laboratories, regardless of the blandishments and allurements from without, which tempt the man of science of to-day. The charm of Prof. Mayer's personality will always remain as a tender recollection to all whose privilege it was to know him.

ROUNDABOUT BY TROLLEY.

ONE of the greatest charms of the bicycle is that it opens up to the wheeling tourist whole regions of beautiful country into which as a pedestrian he was not likely ever to have set foot. All the delights of exploration and adventure are associated with the most modern facilities of locomotion and can be enjoyed without tax of one's powers of endurance. Equally true is this of the trolley car, which is to-day emphatically the chief means of transportation for the great mass of the people. So far a-field do the trolley lines run, and so moderate are the fares, a poor man can now indulge in wide travel and experience that sense of absolute detachment from the everyday surroundings which is not the smallest benefit of a holiday. The radii of these trolley trips are best learned from such a guide book as that published recently by Miss K. M. Abbott, of Lowell, who, in a dainty but inexpensive little manual, lays out for the old Bay State no fewer than sixty sunny days of trolley trips. This book, which can be slipped in a side pocket, is full of good pictures and overflowing with information, and opens up for a tour of reminiscent discovery all the historical spots of Massachusetts in a way that was not possible before the ubiquitous trolley came. And while bicyclists are often worthily indignant at the way the trolleys cut up some of the best rural roads, they can forgive much when as an offset they get such admirable guide books from their friend, the enemy.

ELECTRIC TRANSPORTATION

THE LACHMANN CONDUIT SYSTEM OF ELECTRIC TRACTION.[1]

THE traction system devised by Herr Eduard Lachmann, of Hamburg, is of the underground conduit type, but a special device has been employed to lessen the leakage from the conductor in wet weather and when the conduit is flooded.

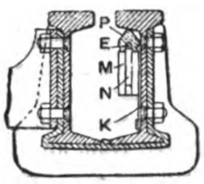

FIG. 1.

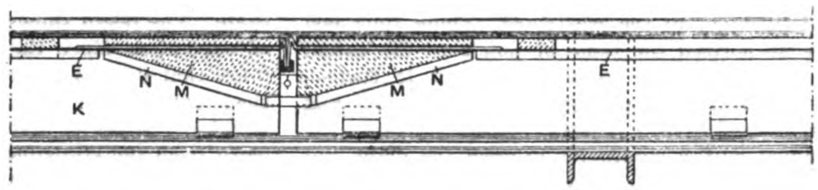

FIG. 2.

Figs. 1 and 2 show the construction of the conduit when it is arranged to take the place of one of the track rails, Fig. 3 shows the form of the collector employed, and Fig. 4 is an elevation of the truck of a car showing the three collectors. In Figs. 5 and 6 is indicated the method of applying the system to an existing track without disturbing the traffic.

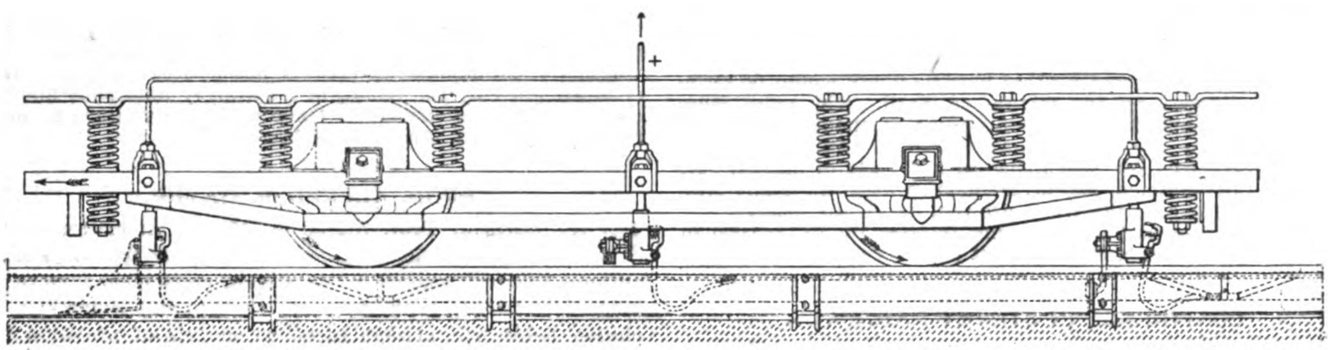

FIG. 4.

Referring to Fig. 1 it will be seen that the sheltered part of the conduit is formed by the pieces K ending in a hood P in which the conductor E runs. This part of the conduit is divided into lengths of about 8 feet, and these lengths are closed at the ends by tapering insulating pieces M, which fit airtight. This hood being closed at the ends constitutes an air-chamber which prevents the water rising as high as the conductor, even if the whole track be flooded. A groove N guides the collector at the joints; its action is clearly seen in Fig. 4.

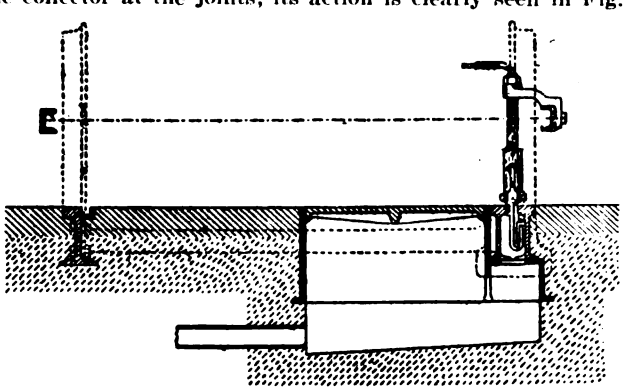

FIG. 3.

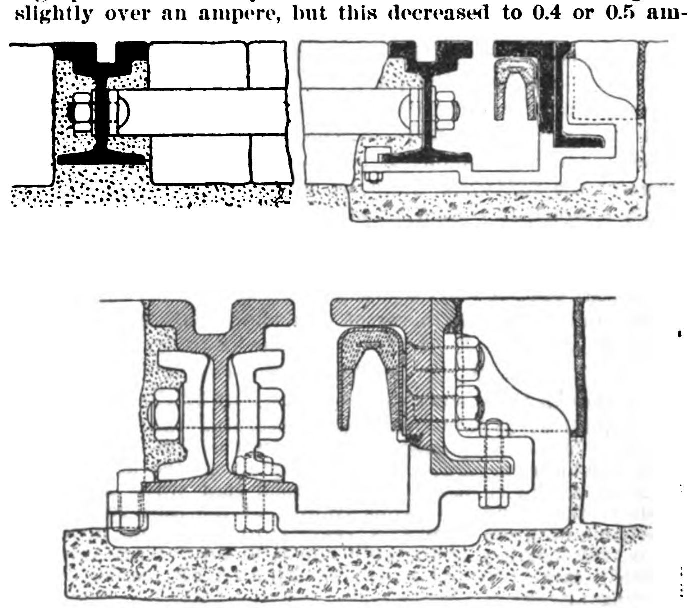
By having three collectors spaced at proper intervals, two are always in contact with the line. This also simplifies the arrangements at junctions. There is a joint in the line conductor at every joint in the hood. The conduit is drained at intervals in the usual way. Among the advantages claimed is that the depth of the conduit is only slightly over 6 inches, in fact no deeper than the rails themselves. The width of the slot can be reduced to ⅝ inch.

Tests have been made on an experimental track in Hamburg by an independent expert. The line was 175 yards long and single track; its greatest curve had a radius of about 100 feet, and the gradients (the maximum being 1 in 15) were so arranged that the whole track could be completely covered with water. The tests were made on a rainy day, and the pressure was 500 volts.

A single section was first tested, with its air-chamber filled with water. It was found that gas was evolved and that in consequence the water was forced away from the conductor and the ammeter returned to zero in a few minutes. The experiment was then repeated, using liquid mud and street filth instead of clean water, and the same results were obtained. After this the conduit was completely flooded, and it was found that the leakage current only amounted to from 0.2 to 0.3 ampere. When the car was in motion the splashing up of the water by the collector increased this leakage to slightly over an ampere, but this decreased to 0.4 or 0.5 ampere when the car reached the upper end of the track. The track tested had been laid nine months, during which time it had frequently been under water, and none of the sections had been renewed. Similar official tests had been made in October by the Hamburg government laboratory, when still better



FIGS. 5 AND 6.

[1]London Electrician.

results were obtained. A trial track 650 yards long is to be laid down in Vienna.

NEW RATING AND NOMENCLATURE OF G. E. RAILWAY MOTORS.

IN response to a letter of inquiry we have received the following details regarding the new rating and nomenclature recently adopted by the General Electric Company for their railway motors:

The company have ceased to rate railway motors by their horizontal effort or drawbar pull, because various combinations of winding and gearing in the same motor are now frequently required, and, of course, the possible horizontal effort of a given motor, say, the G. E. 800, is no longer a fixed quantity. We decided, instead, on a horse-power basis of rating for all of our standard motors, and adopted an entirely arbitrary set of numbers to designate the motors developed since the G. E. 800, 1,200 and 2,000. These last three motors have become so well known that it has been thought inadvisable to change their designating numbers.

The horse-power rating of our railway motors is that which the motors can continuously do for one hour while increasing in temperature up to 75 degs. In comparison between average service and our basis of rating, we find it advisable to furnish motors of such sizes that their average service will be from 20 to 30 per cent. of their horse-power rating. The tests for rating are made with the motor stationary and the cover open, as it has been found that this arrangement approximates the condition of actual service as regards heat radiation; it is also estimated that the temperature of the surrounding air is not more than 25 degs. C. Such a basis of rating fairly represents the conditions of ordinary service and leaves sufficient margin to meet emergencies without injuring the motor.

It should, of course, be clearly understood that the above rating is only aplicable to intermittent work, such as the propulsion of railway cars, and cannot under any circumstances be considered as the rating of the motor for work of a continuous nature.

The following data with regard to standard G. E. railway motors, give their horse-power output on the above basis:

G. E. 800, 27 h. p. at 50 amperes input; G. E. 1,000, 35 h. p. at 65 amperes input; G. E. 1,200, 38 h. p. at 78 amperes input; G. E. 51, 80 h. p. at 140 amperes input; G. E. 2,000, 135 h. p. at 230 amperes input.

DERI'S ALTERNATING-DIRECT CURRENT RAILWAY SYSTEM.

MR. MAX DERI, who is well known in connection with the Zipernowski-Deri alternating system, in Austria-Hungary, has recently brought out a method of operating electric railways by means of a combined system of alternating and continuous current, which is described in the Vienna Zeitschrift für Elektrotechnik.

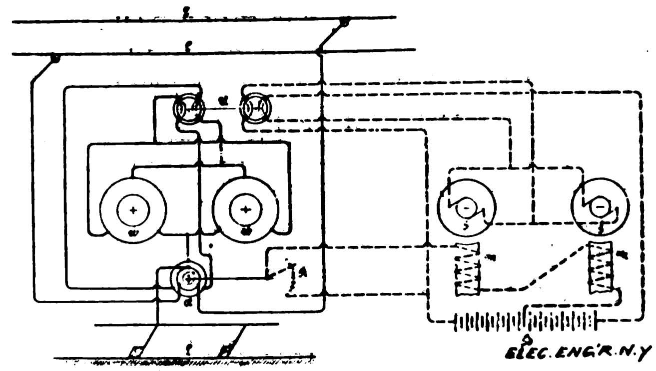
Mr. Deri's system embodies methods for taking advantage of the economy of distribution to be attained with high potential currents and at the same time the utilizing of storage batteries to equalize the load and to assist in the starting of the car from rest, etc.

Single or polyphase alternating currents are led to the line-conductor, either directly or through stationary transformers. Whether the conductor be overhead, underground or on the surface is immaterial to the system, but it should be mentioned that its continuty may be broken at any places where it is troublesome to maintain it, such as at points and crossings, within stations, etc. Connection is made with the conductor in the usual way. Each car or train is equipped with an alternating current motor and a continuous current machine that can run as dynamo or motor. The two machines may be mounted on the same axle or combined as a motor-generator, or some of the axles can be fitted with alternating and the others with continuous current motors. The alternating-current motors receive current from the line, and the continuous current machine is connected to a battery of accumulators carried by the car. The axles of the car or of the train perform, as it were, the duties of a countershafting, and the motors are thus an alternating continuous current transformer and furnish continuous current to charge the cells.

When, as on descending gradients, the power put into the alternating current motor more than suffices to drive the car, the continuous current machine runs as a dynamo and charges the cells. When ascending an incline the power required is more than the available power of the alternating motor, and the battery drives the continuous current machine as a motor. In places where the continuity of the line is broken the battery suffices to drive the car until the line is reached again. As the car can thus be started without the use of alternating current, one can use single-phase alternating current direct from the line. Although single-phase motors will not start under load, it is well known that they work perfectly on reaching a certain speed.

The great advantage of Deri's system of regulation is that the alternating current motors are working under a fairly steady load at their best efficiency, and at the same time the use of a shunt-motor connected to accumulators enables energy to be stored that would otherwise have been wasted. The cells act also as a "buffer-battery," maintaining the demand for current from the machines steady and allowing them to be worked most economically. The capacity and weight of the battery can be relatively small, however, as the chief current it has to deliver is for the starting of the cars.

The connections (with the controller omitted) are shown in the figure. They are from a project of an electric locomotive with four axles, to be worked by three-phase currents. L L L are the line conductors, W the alternating current motor, G the continuous current shunt-motor, M its field-magnets, B the battery, A the automatic regulator, R the regulating resistance, and U the switches for the two circuits. The automatic regulation of the system is apparent from the diagram.



DERI ALTERNATING DIRECT CURRENT RAILWAY SYSTEM.

Its action is to keep the strength of the alternating current between fixed limits, and at the same time the e.m.f. or opposing e.m.f. of the continuous current machine is so varied that the battery is charged or discharged according as the electrical power of the alternating current is in excess or falls short of that required by the car. In the automatic regulator devised by Mr. Deri, the alternating current passing through it to the motor tends to turn an armature against the force of a spring. The turning of this armature turns the arm of a liquid resistance rheostat and increases or decreases the resistance in the field circuit of the shunt-motor. A small change in the speed of the alternating current motor occasions a relatively large change in the current through it, and by means of the automatic regulator this current is kept constant by alteration in the excitation (and therefore the e.m.f.) of the continuous current motor, and thus increases or decreases the load on the alternating motor. In the example shown on the diagram, the exciting circuit is only connected to half the battery, so that the excitation is not affected when the battery is divided into two parallel groups for starting and braking.

During running, the speed of the continuous current machines and the strength of the continuous current is regulated in the usual way by a controller. This controller, which also acts on the shunt coils of the motor, is chiefly used in starting and stopping, and the switching on and off of the alternating current and the braking is also effected by it. Under the circumstances described the well known advantages of a shunt-motor for tramway work will have full effect. The difficulty in making use of these advantages under ordinary circumstances has been that shunt-winding for a pressure of 500 volts could not well be carried out on machines of the size usually employed. In this case, however, the e.m.f. of the battery can be made comparatively low (100—200 volts). The combination of the shunt-motor and battery make, moreover, an excellent braking arrangement, it enables a large part of the kinetic energy of the moving train to be recovered on stopping, and permits of the employment of an exceptionally high torque for starting, etc.

In the case of new tramway systems it is desirable to use a

low periodicity, so as not to cause any troublesome induction effects in telephone circuits. The worst disturbing effects, viz., those caused by the shaking of the brushes, would at all events be entirely absent. Again, the current flowing from the line to the car when it is running does not vary as much in this system of regulation as in the usual system, and the places where large variations in the current occur are at fairly wide intervals. The effect of earth currents is reduced to a very small quantity. By the use of several transformer stations the return circuit is greatly shortened, and, where it is deemed necessary, copper feeders to the return circuit are added. There are, of course, no electrolytic effects on alternating current circuits.

ELECTRIC RAILWAYS IN SOUTH AFRICA.

Henry A. Butters, of Oakland, Cal., has left for Europe on business connected with an English syndicate which has received a concession covering the entire electric street railways of Johannesburg, South Africa. The culmination of this deal throws the entire electric street railway system of South Africa into the hands of the Butters' syndicate. In this transaction several Americans now prominent in South African affairs are heavily interested. Among them are J. K. Waterman, formerly General Freight Manager of the Colorado Midland Railway of Denver; John Hays Hammond, Henry Butters and his brother, Charles Butters, who is now in Johannesburg.

TRAMPS OBJECT TO THE THIRD RAIL.

A special dispatch from New Haven, Conn., of July 7, says: Another attempt was made at a late hour last night to wreck a train load of passengers on the Consolidated Road. This time it was on the third rail of the electric section. The usual plan of piling obstructions upon the track was again carried out, and but for the careful attention of the motorman would have been successful, and a whole car load of people would have been hurled from the track. As in the other cases, the perpetrator of this dastardly deed is unknown, but there is a suspicion that it is the work of tramps who are angry over the railroad people laying the third rail, which renders walking the track dangerous for that fraternity.

ATCHISON AND ELECTRICITY.

Developments of consequence before long will be disclosed in the affairs of the Atchison, Topeka & Santa Fé. There are intimations that large operating economies are likely soon to be put into effect on the system through the adoption of electrical equipment on conspicuous branches of the great system.

LITERATURE

AUFSTELLUNG VON PROJEKTEN UND KOSTENVORANSCHLAEGEN FUER ELEKTRISCHE BELEUCHTUNGS-UND KRAFTUEBERTRAGUNGS-ANLAGEN.—(Prospectus and Estimate of Cost for Electric Lighting and Power Plants.) By Johann Riha. Leipzig; Von Veit & Co. 1897. 5 x 7½ in.; 438 pp.; 198 illustrations. Cloth. Price, $3.20.

There is no work in the English language to which we could exactly compare the book before us. In one sense the work is an anomaly, as it is practically impossible to embody in any general work information that can be directly applied to each single instance arising in practice, where one might say, every case is a special case. What the author has attempted to do is to give a brief description of the principal apparatus which the German market affords, to state what its capabilities or limitations are, and to estimate the proper cost based on what might be called units of light or power, as the case may be.

The part devoted to financial considerations, in which the author estimates the probable profits of a given installation, are well worthy of study. Particular attention has been devoted, and we think justly so, to the subject of depreciation.

Regarding the choice of systems for transmission of power, the author, after describing the various systems available, comes to the following conclusion: 1. That the three-phase system is superior to the other systems in general economy, especially if long distances have to be traversed. 2. The regulation of the three-phase current presents no obstacles. 3. The multiphase motors at the present time are cheaper in cost, more economical in operation, more convenient in handling, and give rise to less disturbances in lighting circuits than the single-phase alternating current motors. We believe that this view of the situation is well borne out by American practice. The author has added to the work a considerable number of tables of price lists of apparatus upon which costs can be estimated, and adds plans of model stations. A book of this kind, based on American practice, would prove a valuable addition to our meager literature on this subject.

TELEPHONY AND TELEGRAPHY

THE MULTIPLE TELEPHONE SWITCHBOARD LITIGATION OF THE WESTERN ELECTRIC CO., vs. THE HOME TELEPHONE CO., OF MOBILE, ALA.

LAST August the Western Electric Company brought suit against the Home Telephone Company, of Mobile, alleging the infringing of the Scribner patent, No. 330,061, of November 10, 1885, entitled "Multiple Switchboards." Testimony was taken subsequently and arguments have recently been concluded before the U. S. Circuit Court, at Mobile.

Three of the seven claims of the patent are alleged to be infringed; they are as follows: ,

Claim 2.—At a telephone exchange central office, the combination of multiple switchboards with telephone lines each permanently connected to a metallic portion of its switch upon each board, each telephone line being also connected through the contact points of its switches and to ground, and means whereby the circuit of the branch wire of any given line is opened when a connection is made with the line at any board, whereby any two lines may be connected together upon either of the boards without including in their circuits the contact points of either of their switches.

Claim 4.—The combination, with a telephone line provided at each switchboard of a multiple system with a connecting bolt or switch, of a portion of said line connected through an annunciator to ground, and means for breaking said line when a connection is made with the telephone line at either one of its bolts or switches, substantially as and for the purpose specified.

Claim 6.—In a multiple switchboard system, a telephone line provided with a spring jack at each switchboard of the system, said spring jacks being provided with insulated metallic frames, and said telephone line being connected directly to each of said insulated frames, and also through an annunciator to ground through the springs and contact points of said spring jacks, whereby a connection may be made direct to the telephone line at any board at the same time the portion of said line containing the annunciator is broken, substantially as set forth.

The accompanying engravings are reproduced from the drawings of the patent.

COMPLAINANT'S ARGUMENTS.—In the brief submitted by complainants, the history of the art is gone into at some length, the testimony of Mr. T. D. Lockwood, one of the witnesses for the complainants, being quoted at length.

As regards the scope of the claims in question, Mr. Scribner, on the witness stand, described the object of his patent to be as follows:

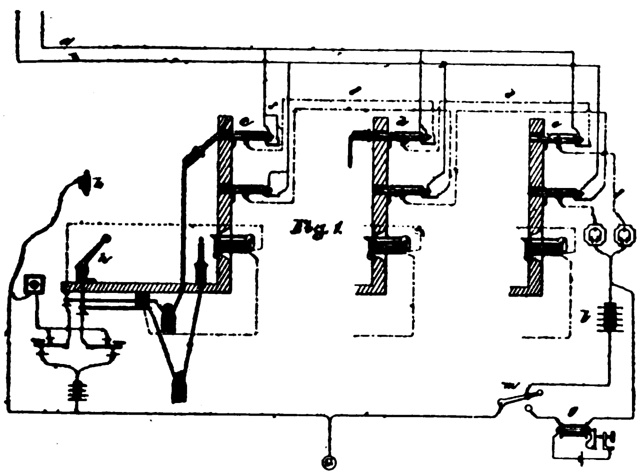
"The patent in suit, No. 330,061, is for a multiple switchboard. The result sought to be accomplished by the invention of this patent is the connection between any two subscribers' lines in a telephone exchange, the exclusion of contact points from the circuit of such connections, while, at the same time, the indicator annunciators of such connected lines are temporarily cut off from their respective lines. A further result of the invention of this patent in suit is the securing of a positive testing system to enable any operator, to determine which of the several lines are in use, or free to be used. The invention of this patent has in its construction spring jack switches, annunciators, connecting plugs and cords, and supplemental devices combined with special and novel circuits, all designed to be operated in a particular way to secure the results referred to."

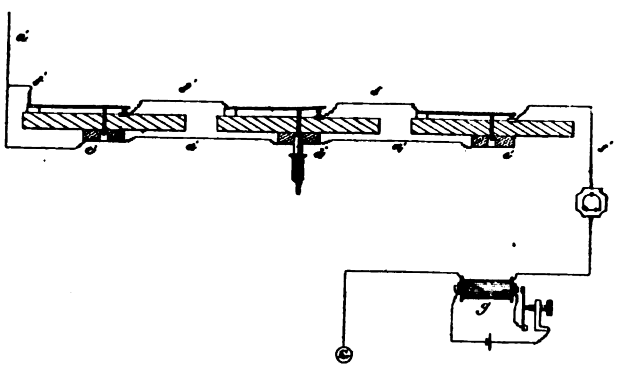
Mr. Scribner, on the witness stand, compared the defendants' system as used at Mobile with the invention of his patent as pointed out in claims 2, 4 and 6, and counsel for complainants characterizes as frivolous the attempts made by the defendants' witnesses to show any distinction, and states

that defendants' witnesses were constrained to admit the essential identity as to construction and mode of operation of the Mobile switchboard and the patent.

As regards the question of the prior state of the art, complainants contend that the other patents of Scribner, cited by defendants, Nos. 292,866, of February 5, 1884; 330,059, of November 10, 1885, and 330,060, of November 10, 1885, do not cover the subject matter of the patent in controversy. Besides, the two last patents cited above, four were issued on the same day as the patent sued on, and hence are deemed irrelevant as prior patents, the law recognizing no parts of a day. One of defendants' witnesses is also quoted as admitting that the getting rid of the feature of the separable contact points of the switches, which constitutes the principal and most important branch of the invention of the patent in suit, is not found in either of the three patents cited as anticipations.

Among the other anticipations urged by defendants in connection with the testimony of Mr. Paul Minnis, were the following patents: No. 252,259, January 10, 1882; C. W. Ross, No. 269,238, December 19, 1882; Shiras & Eckert; No. 294,482, March 4, 1884, Lytle & McCoy; No. 306,669, October 14, 1884, C. H. Wilson. Regarding these patents complainants contend that the patent in suit is essentially a patent for a new combination of what may be conceded are old elements when considered by themselves. The great majority of patents issued are of this character. One charged with infringement cannot, it is urged, justify himself by exploring the prior art and selecting from several different patents, the different elements of the combinations of the complainants' patent. Various authorities are cited in support of this contention.





FIGS. 1 AND 2 OF SCRIBNER'S PATENT NO. 330,061.

Mr. Scribner himself, on the witness stand, commented as follows on the patents cited above:

"As I have stated at the outset of this answer, in substance, none of these references is pertinent; in so far as they relate to multiple switchboards they show only what the specification of the patent in suit concedes to the prior art, and each of them, as I have stated specifically and in detail, contains the objectionable feature of including the contacts of the switches in the talking circuits when formed, which objection or defect is remedied by the invention of the patent in suit."

Taking up the question of infringement, the complainants dwell at length on the drawings of the exchange system furnished by Mr. F. R. Colvin, witness for the complainants, who visited the exchange at Mobile. In reply to the contention of defendants that Mr. Colvin's sketch of the electrical connections in the Mobile exchange showed a busy test arrangement that did not exist at the time of his visit, the complainants urge that the testimony of witness for defendant read in connection with the diagram of Mr. Colvin, shows that the system as operated at Mobile does contain a complete and operative test system, without which the switchboard employed there would be totally inoperative.

The complainants also contend that the defendants have copied so closely the structure described in the patent as to embody every detail set forth in claims 2, 4 and 6, and that such variations as do exist are mere equivalents; even upon the narrow construction contended for by defendants, the latter's apparatus would still contain the invention of the patent, their principal witness having been constrained to admit that defendants' apparatus contains the specific feature of normally open branches or contacts.

DEFENDANTS' ARGUMENTS.—The arguments of the defendants are briefly stated as follows:—

First: There is such failure and insufficiency in the proofs produced by the complainant to establish the charge of infringement that no just determination of that issue is possible.

Second: The state of the art prior to the grant of the patent in suit was such as to preclude the allowance of any claims having the scope and capable of the construction that can be inferred from the terms of said claims and from the face of said patent.

Third: By the well settled construction of the statute, no original patent should have been granted for the subject-matter covered, or defined, by the claims of the patent in suit; such subject-matter having been so far and so clearly disclosed by prior patents to the same grantee that the rights of the latter were thereby relegated to his remedy by reissue, and not to an original proceeding.

Fourth: The patent in suit is not infringed by defendants even if it be admitted, tentatively, that said patent is valid and capable of a broad construction.

Fifth: The patent in suit is void, save as to the seventh claim, under the decision of the U. S. Supreme Court in the case of Miller vs. Eagle Mfg Co., 151 U. S., 201, and Thomson-Houston Electric Company vs. Winchester Avenue Railroad Company et al., 73 O. G., 2,155, and authorities therein cited, and because of the reasons hereinafter set forth.

Sixth: If it be admitted, for the sake of argument, that the patent in suit has any life whatever, the claims in said patent can only be saved by the most narrow construction, rigidly restricting them to the precise form, construction and arrangement shown and described.

I. The whole prima facie case of the complainant rests upon the testimony of a single witness only, he being the only person called by complainant who pretends to have personal or actual knowledge of the things and circumstances to which he testifies. This witness is Frank R. Colvin, an employé of the complainant corporation. Colvin has testified that he was in the operating room of the Home Telephone Company about twenty-five minutes. In this short time he professes to have secured a perfect knowledge of every portion of the switchboard and every circuit upon it.

Colvin has furnished a species of illustration consisting in part of vertical sections and in part of diagrammatic illustrations of circuits. It is termed "Complainant's Exhibit Diagram Defendant's Apparatus," in which he professes to have incorporated what he saw in the defendant's telephone exchange. Concerning this exhibit he has testified: "I know it to be correct as a diagrammatic illustration." He also testifies that "immediately after having inspected the switchboard and having traced circuits of same, I understood the working of the board completely and minutely." Finally, not satisfied with these statements, he also swears: "During the time I was in the exchange I examined not only thoroughly but with great thoroughness" all points connected with wiring of the board.

The testimony of a number of competent, wholly disinterested and intelligent witnesses proves most positively that the so-called "diagram" is an embodiment of numerous errors, inaccuracies and false representations of the grossest character. It is shown that at the time of Colvin's entry to the exchange of the defendants, in Mobile, Mr. Minnis, who was with him during his entire visit, took the precaution of calling another person, Clayton B. Clark, the electrician of the Home Telephone Company, and enjoined him to keep close to Colvin and charge his memory with all that took place. Mr. Clark has testified as to the material and glaring errors and misrepresentations contained in the complainant's Exhibit C, and his testimony agrees, in all substantial respects, with Minnis'. The misrepresentations of the so-styled "diagram" are such as to wholly destroy the effect of the testimony produced in its support.

In reply to questions Colvin refers to the removal of the back of the switchboard, and in no part of his testimony does he express any uncertainty as to this point. John A. Couch, Clayton B. Clark and Paul Minnis all testify that they were in the Home Telephone office, or plant, at the time of Colvin's visit in July, 1896. Each witness swears positively that at the time of said visit there was no "busy test" circuit upon the defendant's switchboard, and that neither prior to said visit, nor subsequently, had there been any such thing upon the switchboard. Clayton B. Clark, who accompanied Colvin and Minnis in the examination of the board, and who had been specially instructed to hear and remember all that was said, testifies that not only was there no test circuit on the switchboard, but that Minnis told Colvin in his (Clark's) presence that a "busy test" could not be applied to said board. The witness swears absolutely and positively to this statement and to the further fact that Minnis did not, during Colvin's stay in the exchange, offer or attempt to show him a test of that kind; that "nothing of the kind was done." Mr. Minnis has described with particularity what took place in the exchange during Colvin's visit. He corroborates Clark in every point.

It is shown also by testimony that cannot be disputed that Colvin's description of the removal of the "back of the switchboard" to expose the wiring is upon all fours with the other parts of his testimony. It appears that this switchboard never had any backing of any sort, and the removal of the latter, which is so often described by Colvin with such repetition of detail, never had any existence except in his own fertile imagination.

Regarding testimony of the character given by Colvin it is submitted the whole is valueless on the principle of the legal maxim, "falsus in uno, falsus in omnibus."

It must be observed, also, that all of the witnesses called by these defendants are not only experts, but that they are without interest in the result of this litigation. Full credit, therefore, must be given to each of them.

The desertion of its own position by the complainant proves beyond question that the entire foundation upon which the suit was originally built has been swept away, and that in the desperate struggle to keep the litigation alive the best that could be done was to attempt, by irrelevant evidence, unwarrantably introduced on rebuttal, to "borrow" planks from the structure of proof erected by defendants upon which to sustain such hope as remained of being able to show the court that, although defendants are not using the arrangement shown in the drawing made, and described and sworn to in the testimony given by their witness Colvin, they are nevertheless using an arrangement which complainant's counsel claims to be the equivalent of that shown and described by their witness Colvin.

II. The patent in suit is for an invention which is an improvement in degree only upon prior inventions, and in said patent the elements of the several combinations are specifically disclaimed, or admitted to be old. The case falls, therefore, under the rule stated in Glover, Sanford et al. vs. Merrimac Hat Company, 2 Bann. and Ard., 408, and Le Roy vs. Tatham, 22 How., 132. This ruling is that—

"Where the invention consists entirely in a new combination of old elements or ingredients the law is well settled that a suit for infringement cannot be maintained unless it appears that the respondent has used all the elements or ingredients of the new combination."

The acknowledgments of the patentee as to the novelty of the elements he was dealing with are found in lines 51, 52, on page 1, of the printed specification. Now, if we examine closely into the exact novelty of the claims in this patent we shall find that the margin of difference between it and the invention in patent No. 321,390, to the same patentee, is not easily defined. The multiple wiring in the latter is identical with that in defendant's exchange.

The patents of Ross, No. 252,259, January 10, 1882, and those of Scribner, No. 330,359 and No. 330,360 are cited as anticipations of the patent in suit. These patents contain every element found in the patent in suit, except the eccentric switch, which is found, however, in patent No. 330,060.

Let us take the jack shown in the Ross patent No. 252,259 and substitute it for the jack shown in either of Scribner's patents Nos. 330,059 or 330,060. This, also, would give us in every particular the exact combination of the claims in the patent in suit.

It may well be asked, of what importance to the combinations in the patent named is the insulation which isolates the spring switch from the metallic frame? Or, in other words, why should this device be in electrical connection with the metal frame in patent No. 292,806 and insulated from it in 330,061; or, for that matter, in 330,060 or 330,059? What would be the result of removing the insulation around the spring switch in any of these patents? Clearly it would act in precisely the same way in both forms. That this view of the construction is correct beyond all disputation is shown by the second figure of the drawings in the patent in suit. In said figure we find no insulation whatever around the spring switch, but a non-conducting bolt lies in the jack and is pushed by the plug against the spring to open the circuit of the annunciator.

This fact establishes beyond contention that the substitution of the Ross jack for the jack in patent 330,060 would be entirely feasible, and would not even require ordinary mechanical skill. The production of the invention in the patent in suit was not a matter requiring inventive skill. It was accomplished by others who never considered it a subject for a patent.

The line being connected directly to the body of the jack and a tap or branch taken from it directly above the jack and connected to the spring switch, we have an arrangement exactly equivalent in all respects to that produced by simply removing the insulation from the spring. This view was taken by the Patent Office when the application for the patent in suit was pending. Why it was not adhered to can only be understood by remembering that the Patent Office is fallible, like all human institutions.

We also refer the court to the recent decision of the U. S. Supreme Court in Miller vs. Eagle Manufacturing Company et al., 151 U. S., 186, and to the case of the Thomson-Houston Electric Company vs. Winchester Avenue R. R. Co., 73 O. G., 2,155, in which the authority first cited is examined and explained.

III. In Magin vs. McKay, 24 Fed. Rep., 743, it was said that:

"Prior use of articles less perfect, but identical in principle, invalidates a patent."

Authorities can be cited by volumes showing the close scrutiny the courts are exercising in patent litigation in order to establish the validity of their claims and determine the construction to be given the same. It is unnecessary to say that in cases where the alleged novelty is of a character which negatives the presumption that inventive effort was necessary for its production the claim or claims to such features must be declared invalid.

V. It is well settled that where the evidence of infringement is not clear it is insufficient. (Hill vs. Holyoke Envelope Co., 20 Fed. Rep., 683; Rey vs. Ram, 16 Fed. Rep., 749.) Also that in combination claims the absence of a single feature recited in said claims will overcome the charge of infringement. (P. H. Murphy Mfg. Co. vs. Excelsior Car Roof Co., 76 Fed. Rep., 965.) We have already directed attention to the fact that where a patent covers merely combinations of old elements the law is well settled that a suit for infringement cannot be maintained unless it appears that the respondent has used all the elements or ingredients of the new combinations. (Glover, Sandford et al. vs. Merrimac Hat Co., 2 Bann. and Ard., 408, and Le Roy vs. Tatham, 22 How., 132.) It is settled, also, that "when the state of the evidence is such as to leave doubt in men's minds the doubt will be resolved in favor of the defendants and they will be held not to infringe." (Mallory Mfg. Co. vs. Hickok et al., 25 Fed. Rep., 827. (1885) Shipman, J.)

It having been clearly shown by the proofs referred to that there was absolutely no "busy test" upon defendants' board, it follows that they cannot be charged with trespassing upon any claims in the patent in suit in which testing apparatus is made an element. Therefore, they cannot be charged with infringement upon the first, third and fifth claims in patent No. 330,061.

As to the remaining claims expert witnesses agree that defendants have, in their apparatus, no "normally open branch," or any equivalent thereof.

TELEGRAPHERS AND YELLOW FEVER.

Every announcement of the arrival of a vessel at an American port with cases of yellow fever on board sends a thrill through the telegraph operators of the country, especially those employed in Philadelphia and other Pennsylvania cities, the "Press" says. In 1878, when the "saffron scourge" was almost depopulating the cities of the South, hundreds of Southern operators died, and, as the mails had been quarantined, there was a possibility for a time that all communication between the North and South would be shut off. Although the Western Union Company did not ask for volunteers among Northern operators to go South to keep communication open, seven men offered their services. Four were employed in Pittsburg, two in Philadelphia and one in Boston. The four Pittsburg men went to Memphis and all died of the fever within a few days after their arrival. The Boston man started for New Orleans and accidentally shot himself in a

New York hotel. One of the Philadelphians, on his way South, was arrested and sent to jail in St. Louis on a trumped-up charge preferred by his mother, who took this means of preventing her son from risking his life. The seventh volunteer, also from Philadelphia, reached New Orleans safely, was not ill a day and was the only one that reached the yellow fever country that year and returned alive.

ELECTRIC MOTORS IN FARRELL FOUNDRY AND MACHINE CO.'S SHOPS, ANSONIA, CONN.

An interesting example of electric drive in a heavy machinery works, is that found in the shops of the Farrell Foundry and Machine Company, at Ansonia, Conn., the electricity being taken from turbine driven generators located nearly three miles away.

Previous to the development of the water power, the generating plant of the Farrell Foundry and Machine Company consisted of two 75 k. w. six-pole, 275-revolution, 500-volt dynamos, directly coupled to 100 h. p. Ames engines, and one four-pole, 65 k. w., 220-volt generator, driven by belt. The latter still furnishes current to three traveling cranes, the former during a short space of time only during the year drives the different motors scattered throughout the shops. This plant was purchased before the Derby Gas Company arranged with the Farrell Foundry and Machine Company to supply it with current from its power station at the Housatonic Dam, where it utilizes the excess water flowing over the dam. The Derby Company having two four-pole, 200 k. w., 550-volt machines and being thus in a position to supply power, made a favorable arrangement with the Farrell Company.

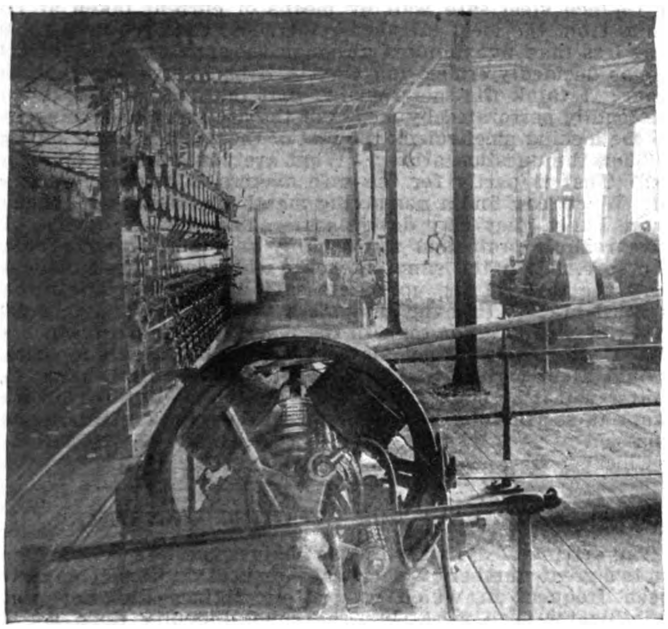


Fig. 1.—Power Station, Farrel Foundry and Machine Co., Ansonia, Conn.

Both dynamos being direct current machines, and the length of the transmission nearly three miles, they are coupled in series to secure the necessary pressure, and deliver current at the brushes at 1,100 volts. At the switchboard, at Ansonia, the pressure is 1,000 volts. The distribution is carried out on the Edison three-wire system, and as half the motors in the works are connected to each side of the system, the working pressure of each motor is 500 volts.

In the engine room at Ansonia is a switchboard of the panel type, arranged not only for the complete control of the motor plant operated from Derby, but also for the isolated plant of the Farrell Company. The two 75 k. w. generators in the Farrell works are used for about two months only in the year, the current from the Housatonic Dam being used for the other ten months. The first two panels control the two 75 k. w. generators; the third is an "Outside Supply" panel and then come ten panels, each controlling two motors.

The motor equipment consists in all of nineteen motors of the following horse-power and speed: Three 35 h. p., 525 revolutions; five 10 h. p., 325 revolutions; five 15 h. p., 312 revolutions.

They are all of the four-pole type, and for the most part are located directly over the floor of the shop on platforms suspended from the roof girders. From these the belts are taken to the shafting below, whence the various machines are driven. The illustration, Fig. 2, shows six motors set on platforms in the new machine shop. They range in capacity from 10 to 35 h. p. Directly beneath them is the path of one of the traveling cranes. Other motors are attached to the wall, and a few are on the main floor near the walls.

The machinery manufactured by the Farrell Foundry and Machine Company is of a peculiarly heavy type and the machines driven by the motors are of various characters and sizes, subjected to sudden, heavy and fluctuating loads, yet according to the officers of the Farrell Company, the plant, running since October, 1895, has, not only given complete satisfaction, but no repairs either to generators or motors have been found necessary during the eighteen months in which the system of electrical drive has been in operation. The heavy ore and rock crushers made by the Farrell Company are used in all parts of the world, while their mills and heavy calendar rolls are found in nearly every rubber mill in the United States.

The economy induced by the introduction of the electric motors is perhaps best illustrated by the result obtained in the roll shop. This was previously run by a 250 h. p. Buckeye engine, usually loaded to its full capacity. The same rolling machinery, as well as a variety of other machinery, is now driven by motors, taking a total power of from 125 h. p. to 150 h. p.

The 65-kilowatt, 250-volt generator supplies as stated above the current to operate three traveling cranes and several jib cranes. The machine is also subjected to very wide fluctuations of load, sometimes extremely severe. Under service of this character the ordinary generator might be expected to give some dissatisfaction, yet it operates without the least

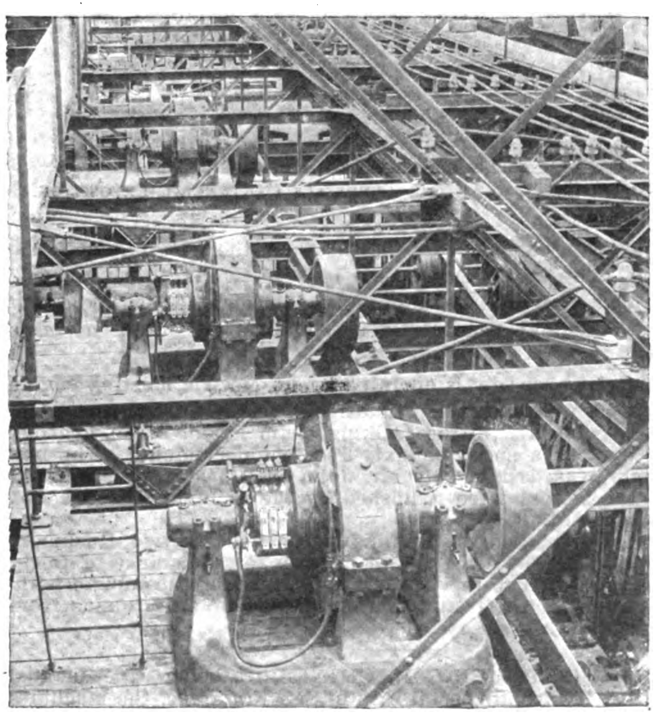

Fig. 2.—Six 500-Volt Motors Attached to Roof Girders in New Machine Shop, Farrel Foundry & Machine Co., Ansonia, Conn.

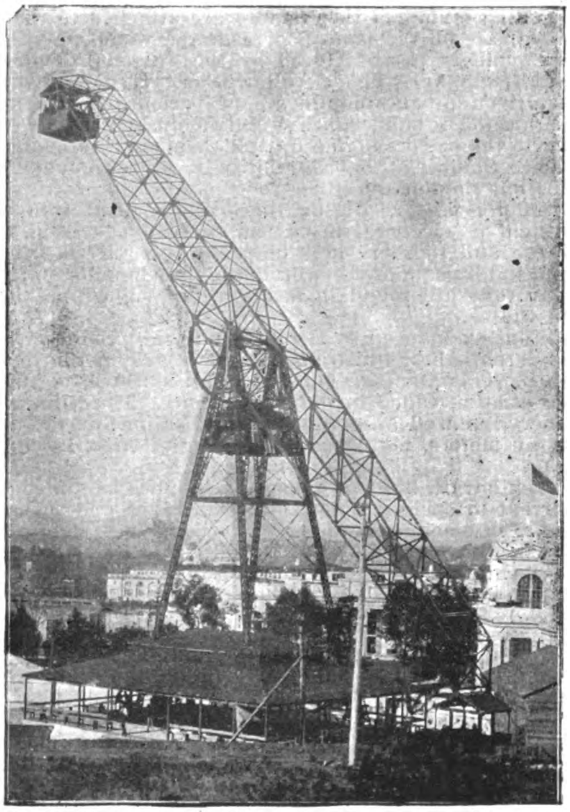
sparking and without necessity of changing the brushes, under any change of load.

The entire electrical plant was furnished by the General Electric Company.

THE GIANT SEE-SAW AT THE TENNESSEE CENTENNIAL.

PARIS has had its Eiffel Tower, Chicago its Ferris Wheel and the Tennessee Centennial at Nashville has as its great land-mark the Giant See-Saw. This unique structure was designed and constructed by Mr. A. J. Dyer, a prominent engineer of Nashville, the steel work being furnished by the Schultz Bridge Company, of Pittsburg, Pa. The tower rests on stone foundation running down to solid rock, and is 100 feet high, while the truss beam, from either end of which a car capable of carrying twenty-five people is suspended, is 200 feet long, thus giving a maximum height of 200 feet, from which point a most magnificent view of the Cumberland Valley can be had. In the distance, the "Hermitage," the home of Andrew Jackson, can be seen, while "Belle Meade," the forts and battlefields of Nashville, together with the city and Centennial grounds lie in beautiful panorama at one's feet.



GIANT SEE-SAW AT THE TENNESSEE CENTENNIAL EXPOSITION.

The giant see-saw is operated by an electric hoisting engine equipped with a 10 h. p. multipolar motor direct connected, and is connected to the walking beam by means of gearing. The car has a speed of sixty-five feet per minute. The machinery was designed by Mr. John W. Chester, of Nashville, and the motors were furnished by the Triumph Electric Co., of Cincinnati, O.,

A novel method of illuminating is had by two Rushmore searchlights; these lights can be seen for a distance of thirty miles. No visit to the Centennial is considered complete without a view of the beautiful illumination of the grounds from the top of the see-saw.

LETTER-STAMPING MACHINES are being experimented with on the trolley postal cars in San Francisco, the machines being run by motors that take current from the trolley circuits.

BROOKLYN TROLLEYS carried 700,000 passengers on Monday, July 5, and not a single accident of any importance occurred. The Sunday travel was almost as large and probably reached 600,000 passengers. The cars were run on the shortest possible headway, but even then had twice as many fares as the law allows. There was no keeping the people off.

LETTERS TO THE EDITOR

SAFE BURGLING BY ELECTRICITY.

THE editorial in your issue of July 8 as well as some remarks in earlier numbers would imply a forgetting of that apt phrase of Dr. Holmes: "There somewhere is always a weakest spot." It seems to me that the burglar who is sufficiently wideawake to employ electricity for his work will also be bright enough to know the weak spots in a safe mechanism. All the safes with which I am familiar have the bolt movement controlled by detents in the shape of a series of washers or "tumblers," which are light and rather frail, so that they could easily be forced off the supporting shaft by a few well directed blows. Then when they are displaced the safe can be opened by merely throwing the handle, without the use of any explosives. All the intruder would want of the current is a means of getting access to this weak spot in the locking mechanism of the safe; he knows just where the tumblers are located and a fairly small hole through the door will be ample for introducing a tool with which to destroy the detent.

That such a hole can be readily burnt through the safe door by means of an arc, has been well affirmed by writers in your columns. I myself have seen a ¾-inch hole burnt through a 1½-inch steel safe wall by means of current taken at 110 volts from the local Edison circuit. The time required for it was less than five minutes, although the apparatus used struck me as decidedly crude; and what if it had taken, say, half an hour? I think the fact remains that the door of a safe can be readily perforated by means of the arc so as to give access to the locking mechanism; the rest of the work is plain sailing.

Then the question arises: "What are you going to do about it?" That is partly for the safe makers to answer; perhaps Mr. Wurts can find a non-arcing metal for them. Or, what is more likely, they may devise some alarm devices which will give reliable protection against any sort of tampering with the safe. Then the same agencies which are threatening to ease the work of the up-to-date safe breaker may be turned against him, so that the banker's safeguard may lie in a network of wires rather than in the massive plates on which so much reliance has been placed in the past. Such a change would seem logical, and the sooner it is brought about the better will it be not only for the safe owners, but for all who want to see the electric current used only for legitimate purposes.

ALBERT SCHEIBLE.

Chicago, Ill.

GAS ENGINES FOR ELECTRIC LIGHTING.

The driving of dynamos by gas engines has been commented on in a great number of electrical papers. Doubtless there have been frequent in which gas or oil engines did not prove suitable for such work, but the chief difficulty does not lie with the gas engine in general, but with some of the makes selected for dynamo-driving. If, therefore, an engine be chosen especially designed for electrical work, the result will be quite a satisfactory one.

Most gas engines are built on the hit-and-miss principle of regulation. To keep the speed fairly steady—especially at light loads—a one cylinder engine has to run at a very high speed and must be provided with heavy flywheels and a sensitive governor. Frequently two cylinders are coupled together, and the result obtained in regard to steadiness of speed is in most cases a good one. This construction is rather expensive for smaller engines and materially complicates the machines, so that—at present—the best solution seems the use of another system of speed governing of single cylinder gas engines.

Having tested, within the last four years, a great number of gas engines driving dynamos, I can state that the regulation of the speed by varying the quantity (not quality) of the explosive charges must be considered the most successful. Some of the engines working on the hit-and-miss principle of speed regulation showed, between explosions, a continuous speed variation corresponding to a change of from 4 to 10 volts on a Weston voltmeter, while engines regulated by varying charges gave variations of ½ to ⅓ volt, a result which compares favorably with the working of good steam engines.

Last winter I took occasion to study the working of a 10 h. p. gas engine designed by Mr. H. Carnell, of Dayton, O., for electric light work. The maximum variation of the voltage was less than ½ volt, and a tachometer indicated a greater variation (in per cent.) of the dynamo speed than of that of

the gas engine. The dynamo, however, was running under very unfavorable conditions, as its position was much too low and the dynamo pulley was of very small size in order to attain the proper speed without countershafting. The engine was easily started and never failed to work the time that I saw it in operation in Dayton.

A great many of the failures in gas engine plants must be attributed to the insufficient size of the gas engines employed, and since a great many of such cases occurred to me, it seems that a closer attention should be paid by the purchaser of a gas engine to the actual (brake) horse power of such machines.

DR. G. H. BENNETT ZAHN, C. E.

Berlin, July 3, 1897.

ROENTGEN RAYS

PROF. ROENTGEN'S LATEST RESEARCHES.

Prof. Röntgen has again made a communication to the Royal Academy of Sciences on his great discovery. He states that while the X-rays are passing through the air they traverse it in every direction. When a plate impervious to the rays is placed between a fluorescent screen and a source of the rays, so that the screen is overshadowed by the plate, the platinocyanide of barium nevertheless becomes luminous, and this luminosity is visible even when the screen lies directly upon the plate, so that one might imagine that some rays had traversed the plate; but if the screen placed on the plate is covered by a thick piece of glass the fluorescence becomes weaker and disappears completely when the glass is replaced by a cylinder of lead 0.1 centimetre (equals 1-25th of an inch) in thickness surrounding the fluorescent screen. Prof. Röntgen's explanation of this phenomenon is that X-rays emanate from the irradiated air. He considers that if our eyes were as sensible to the X-rays as to ordinary light the appearance would be as if a candle were burning in a room filled with tobacco smoke. Prof. Röntgen has, moreover, invented a new apparatus for measuring the intensity of the X-rays. He has succeeded in ascertaining by means of this apparatus that the intensity of the rays is influenced: (1) by the course of the primary current; (2) by the interposition of a Tesla transformer; (3) by the rarefaction of the air in the tube, and (4) by some other agencies not yet known. He concludes: (1) that the rays issuing from a discharging apparatus consist of a mixture of rays of different absorbability and intensity; (2) that the combination principally depends on the course of the discharging current; (3) that the absorption of the rays varies according to the absorbing medium, and (4) that as the X-rays are produced by the cathode rays, and have similar fluorescent, photographic and electrical qualities, it is very probable that they are both phenomena of the same nature.

NATURE OF ROENTGEN AND OTHER RAYS.

An elaborate paper on the subject of Röntgen rays as compared with other occult types of radiation has been read before the Heidelberg University by Julius Precht. He reproduced several photographs tending to show that the bending of cathode rays in a magnetic field is strictly in accordance with the Biot-Savart law and the theory of electrodynamic tension. Goldstein's "canal" rays hold a distinct place with regard to both cathode and Röntgen rays. They are not deflected by a magnet, and they have no powers of exciting fluorescence or photographic action. Röntgen rays show various properties with regard to absorption which have not yet been noticed. Metals, glass, and crystals absorb them to a different extent according to the percentage of slight impurities, and also according to the structure of the molecule. They are capable of altering the resistance of a selenium cell to the extent of 32 per cent. The decomposition of dry salts by the rays of the second cathode layer, as observed by Goldstein, cannot be obtained by the Röntgen rays. An important point is raised by the observation that the amount of absorption by paper undergone by the Röntgen rays depends upon the time during which the radiation lasts. The author regards a portion of this action as purely electrical, and concludes that part at least of the rays proceeding from the discharge tube does not consist of wave motion. In this conclusion, and in the surrendering of the argument from the absence of effect upon the magnetic needle, there is a distinct step toward what is known as the English view. On the other hand, the author claims certain interference phenomena for Röntgen rays, and tries to determine their wave length à la Fomm and Sagnac. By the interference of a direct ray and a ray reflected at grazing incidence by a lead plate he obtains the values of 370 $\mu\mu$ and 830 $\mu\mu$ for two experimental arrangements. These, it will be noticed, are the two extreme limits of the visible spectrum. Here there is a difficulty to solve, for if these rays are transverse ether vibrations of the frequency of light, they should be distinctly visible to the ordinary eye. The dilemma may be escaped from by assuming that the vibrations are not transverse, but longitudinal. The author inclines to accept this view rather than doubt his wave length determinations.

LUMINESCENCE.

A valuable and systematic investigation of luminescence phenomena as produced by all sorts and conditions of rays has been carried out by W. Arnold. The rays employed comprise light, cathode, Röntgen, Becquerel, "canal," and discharge rays, and the substances examined include sulphides, selenides, tellurides, organic bodies and solid solutions. Among the results obtained there is a noteworthy proof that the results obtained with solid solutions cannot be obtained by a mere intimate mechanical mixture of the two substances. Further, there is a very decided difference in the luminescence of various bodies under the influence of cathode rays and X-rays, respectively. This is prominently brought out by the solid solutions of manganese sulphates in other sulphates which are quite indifferent to Röntgen rays. A similar discrimination is shown by anthracene, toluidine, benzoic, salicylic and hippuric acids, and other organic bodies, including bacteria. The most brilliant solid solutions fail to send out Becquerel rays. One hydrocarbon—retene—does emit them, whereas closely allied bodies like anthracene and anthraquinone do not. The "canal rays," first obtained by Goldstein from the red cathode rays by perforating the cathode, have some remarkable properties. They are not deflected by a magnet, but, like the cathode rays, they are capable of producing an intense luminescence, which is, however, only temporary, as the bodies rapidly lose this property under their influence. Apart from this difference from the cathode rays, they are distinguished from X-rays by their lack of photographic action. They are, however, capable of discharging bodies electrified either positively or negatively. Their energy is very great, as shown by their heating effect. It is possible that the heating of the unperforated cathode is chiefly due to them. The phenomena of luminescence offer a valuable test for distinguishing between the various types of rays.

SOCIETY & CLUB NOTES

A. A. A. S. MEETING AT DETROIT.

The meeting of the American Association for the Advancement of Science to be held at Detroit, August 9 to 14, promises this year to be of unusual interest to electricians, and it is expected that a large number will attend. Prof. A. G. Greenhill, of Woolwich; Prof. J. V. Jones, of Cardiff, and Profs. John Perry and W. E. Ayrton, of London, have signified their intention to be present and participate in the proceedings of the Physics Section. The names of Mr. C. P. Steinmetz, Mr. Chas. F. Brush, Prof. H. S. Carhart, and other eminent electrical engineers are on the programme. Those who wish to be present at the meeting and are not already members should apply to Dr. Frederick Bedell, secretary of the section, Ithaca, N. Y., or to Prof. Putnam, the permanent secretary, Salem, Mass.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION.

A very interesting historical sketch has been issued of the work done in making the rules that govern electric light and power work in this country. It bears the names of Prof. F. B. Crocker and Mr. C. M. Goddard, and has been prepared by the Code Committee of the National Conference on Standard Rules and the Committee on Press of the Underwriters' Na-

tional Electric Association jointly. Our readers are familiar with the course of events here narrated, but many of them will probably be glad to secure a copy of this record in its succinct and handy form.

OBITUARY

PROF. ALFRED M. MAYER.

Alfred M. Mayer, professor of physics in the Stevens Institute of Technology, Hoboken, N. J., and one of the leading physicists of this country, died on July 13, at his residence in Maplewood, N. J., after a protracted illness. He was born in Baltimore, Md., November 13, 1836, and was educated at St. Mary's College in that city, from which he graduated in 1854, entering the workshop and drafting room of a mechanical engineer, where he remained two years. He then devoted two years to the study of analytical chemistry. When he was little more than 20 years of age he was called to the chair of physics and chemistry in the University of Maryland, and three years later accepted a similar position in Westminster College, Missouri, where he remained for two years, and then went abroad to complete his scientific education at the University of Paris. There he studied physics, mathematics and physiology under Regnault, the great French scientist. Returning from Paris, he was appointed to the chair of physics in Pennsylvania College, at Gettysburg, and subsequently held the chair of physics and astronomy at the Lehigh University,

Prof. Alfred M. Mayer.

Bethlehem, Pa. On the organization of the Stevens Institute of Technology, in 1872, Professor Mayer accepted the professorship of physics at that institution, which was filled by him from that period up to the time of his death.

His scientific researches since that time have been principally published in the American Journal of Science, under the title of "Researches in Acoustics." These include a method of detecting the phases of vibration in the air surrounding a sounding body, mode of measuring the wave lengths and velocity of sound in gases, resulting in the invention of an acoustic pyrometer; the determination of relative intensities of sound; five new methods of sonorous analysis for the decomposition of a compound sound into its elementary tones, and several other important discoveries in the field of acoustics.

One of his most important contributions to the physics of music is a paper on "The Determination of the Law Connecting the Pitch of a Sound with the Duration of Its Residual Sensat on." Other treatises he published were: "On the Effects of Magnetization in Changing the Dimensions of Iron and Steel Bars," "Experiments with Floating Magnets" and "On Measures of Absolute Radiation." His most recent work was devoted to the investigation of the phenomena of floating polished metal rings. In all, he was the author of nearly 100 articles and pamphlets dealing with the several branches of science which he devoted nearly all his life. Professor Mayer was of a strong mechanical turn, and invented a number of machines and apparatus used in the laboratory of the physicist. In 1866 he received the degree of Ph.D. in the Pennsylvania College, and six years later was elected a member of the National Academy of Sciences. He was also one of the associate editors of the American Journal of Science and a member of a number of scientific associations.

PERSONAL

PROF. R. B. OWENS, of the University of Nebraska, is a visitor to New York, en route to the Institute meeting at Greenacre, Me. He has been very successful in his work of securing exhibits as Commissioner for the Electrical Section of the fine Exposition to be held at Omaha next year.

MR. H. N. FENNER, of the New England Butt Works, Providence, R. I., went abroad recently with his wife for a summer holiday.

MR. C. O. MAILLOUX, accompanied by his wife, has gone abroad on a short trip.

MR. H. B. COX sailed for Europe last week on the "Campania," hoping soon to return to the United States, where he has been much gratified with his reception.

LEGAL NOTES

JUDGE CULLEN, of the Appellate Division of the Supreme Court in Brooklyn, has decided that the franchise of the Brooklyn City Railroad is not a taxable asset.

THE BELL TELEPHONE COMPANY, of Philadelphia, has secured a decision from the Common Pleas Court, to the effect that the city must grant permits to erect poles at certain points; and a writ of peremptory mandamus is issued.

CAR SPEED. The Appellate Court has sustained the decision of the County Court, which fined the Nassau Electric Railroad Co. $25 for running a car faster than the authorized speed of ten miles an hour.

THE STOCK MARKET

CLEARING SKIES.

THE conditions of the country, the tone of the stock market, and the general outlook in agriculture and trade, all mark the beginning of a better state of affairs. In fact, it might be said that evidence had been given of this improvement for some time past, but while this is true, no deep impression had been made in any quarter. For some time to come the old complaints will be heard, and there will here and there be justification; but the attitude of the public is that of cheerful hope, and the broad movement is towards a large prosperity.

Last week 10,949 shares of Western Union were sold up to 85⅛. Of General Electric, 10,796 shares were sold, up to 34¾; and American Bell Telephone on sales of 224 shares rose to 229½.

Copper ingot is quoted at 11⅛c. to 11¼c. for Lake, 10¾c. for electrolytic, and 10½c. for casting.

RAILS are quoted at $19 for heavy steel, and $24 to $28.50 for light sections.

BOILER TUBES. At a manufacturers' meeting in New York, July 13, the following scale was adopted:

	Discount. Per cent.
Merchant Boiler Tubes, 2½ and larger	.80
Merchant Boiler Tubes, smaller sizes	.77½
Charcoal Iron Boiler Tubes, 2½ and larger	.75 and 5
Charcoal Iron Boiler Tubes, smaller sizes	.72½

An additional 5 per cent. is given to the trade.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 13, 1897.

Alarms and Signals:—

THERMOSTAT. O. Wiederhold, Summit, N. J., 586,301. Filed November 14, 1896.
Comprises a thermostat and thermostatic alarm arrangements particularly applicable to dynamos and motors.

Batteries Primary:—

PRIMARY BATTERY FOR BICYCLE LAMPS. T. F. Boland & H. C. Hubbell, Elmira, N. Y., 586,416. Filed December 24, 1896.
Comprises the casing, a metallic rod, the lower end of which is embedded in the bottom of the casing, while its upper end is vertically slotted, and a zinc element provided with a hollow seat, to adapt it to fit over the metallic rod.

Conductors, Conduits and Insulators:—

RACEWAY FOR ELECTRICAL CONDUCTORS J. H. Bleoo, Brooklyn, N. Y., 586,282. Filed April 13, 1897.
A raceway for the reception of a bare electric wire, the raceway having an exposed inner metallic surface and capable of being bent in combination with means for insulating the raceway from surrounding objects.

INSULATOR. H. W. Steinberg, Jr., Walla Walla, Washington, 586,372. Filed December 3, 1896.
Consists of a block of glass or other insulating material, a screw secured in the block, by means of which the same may be attached to a suitable support, the block being further provided with an irregularly-shaped slit in its upper end in which the line wire is adapted to fit, and with an opening extending laterally through the block and passing through the slit at a point just above its lower end, and a securing wire fitting within the opening.

JOINT PIECE FOR ELECTRICAL CONDUCTORS. E. Ivins, Philadelphia, Pa., 586,439. Filed November 11, 1896.
Consists of a seamless tube having its sides indented so as to form three independent tubes arranged in triangular form.

CABLE HEAD FOR ELECTRIC WIRES. H. A. Tobey, Toledo, Ohio, 586,464. Filed March 5, 1897.
A casement and an annular disc secured in the casement for affording ready access for change in wire connections, the disc provided with means for connection of the wires.

CABLE HEAD FOR ELECTRIC WIRES. H. A. Tobey, Toledo, Ohio, 586,464. Filed March 5, 1896.
Similar to above.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE OR ELECTRIC MOTOR. A. R. Grieboy, Baltimore, Md., 586,234. Filed June 2, 1896.
A radial-pole armature machine capable of working either as a dynamo or motor in series, shunt, or compound wound.

DYNAMO OR MOTOR. A. W. Smith, Washington, D. C., 586,459. Filed May 3, 1897.
Employs a field magnet having on one side of its neutral point a single wide pole and on the other side of the neutral point several plural poles, the plural poles forming between them coil containing spaces.

COMMUTATOR-TRUING DEVICE. Percy B. Bosworth, Fort Wayne, Ind., 586,514. Filed December 17, 1896.
Details of construction.

Electro-Metallurgy:—

PROCESS OF AND APPARATUS FOR ELECTROREFINING COPPER OR OTHER METALS. C. R. Fletcher, Boston, Mass., 586,171. Filed January 27, 1892.
The method consists in heating the cathode of an electrodeposition tank, by introducing steam into the hollow interior of the same, and superheating the steam by passing a current of electricity through resistance coils contained within the cathode.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. B. A. Stowe, Cleveland, Ohio, 586,208. Filed December 28, 1896.
Comprises the carbons, the globe and a light obstructing device at a point within the globe which is at all times in the light field space of the arc.

INCANDESCENT ELECTRIC LAMPS. H. F. Schaedel, Cleveland, Ohio, 586,275. Filed July 6, 1896.
Contains two carbon filaments, with a common return circuit.

ELECTRIC LIGHT FIXTURE. L. McCarthy, Boston, Mass., 586,-317. Filed March 18, 1897.
Employs an intermediate insulating disc between the canopy and ceiling formed with an annular groove in which the edge of the canopy rests.

ADJUSTABLE SUPPORT FOR INCANDESCENT ELECTRIC LIGHTS. C. A. Carmany, Ephrata, Pa., 586,378. Filed March 22, 1897.
Details of construction.

ELECTRIC LAMP FOR VEHICLES. M. P. Ryder, Westfield, N. J., 586,399. Filed September 10, 1896.
Comprises a headlight supplied with current by a magneto-electric generator adapted to fasten to the fork of a bicycle and adapted to be driven by friction with the wheel.

ARC LIGHT HOLDER. Chas. A. Haney, Pittsburg, Pa., 586,435. Filed February 19, 1897.
Comprises a pole and cross-arm and means whereby the lamp may be readily moved to any position on the cross-arm.

Miscellaneous:—

PROCESS OF ELECTROLYTIC DECOMPOSITION OF SOLUTIONS. L. P. Hulin, Modane, France, 586,236. Filed July 6, 1894.
Consists in subjecting an electrolyte to the action of porous electrodes having only one electrically active surface exposed to the pressure of the electrolyte while the other electrically inactive surface is subjected to a lesser pressure and gives passage to the ions.

ELECTRIC IGNITER FOR GAS ENGINES. Harry S. Dosh, Baltimore, Md., 586,479. Filed February 17, 1897.
Comprises two electrodes having their ends formed as extended plates and means for suddenly separating the plates thereby causing a rarefaction of the gaseous medium between them.

ELECTRIC TELPHER TOWING SYSTEM. H. F. Gray, Passaic, N. J., 586,516. Filed February 14, 1894.
Comprises a series of poles located outside of the tow-path and braced against lateral and longitudinal strains, electric tracks or cables, one mounted upon the braces and another upon the tracks, and means for connecting the motor to a canal boat.

ELECTRIC GAS LIGHTER. F. Rhind, Bridgeport, Conn., 586,537. Filed May 17, 1897.
Details of construction.

Railways and Appliances:—

TAKE-UP DEVICE FOR TROLLEY CORDS. A. J. Wood, Springfield, Mass., 586,302. Filed April 9, 1897.
Comprises a spring actuated roller enclosed within a casing.

ELECTRIC RAILWAY SYSTEM. L. K. Devlin, Havre, Montana, 586,422. Filed May 24, 1895.
Sectional conduit system.

Switches, Cut-Outs, Etc.:—

METHOD OF AND MEANS FOR SUPPORTING AND INSULATING ELECTRIC CONDUCTORS. H. W. Leonard, East Orange, N. J., 586,133. Filed February 13, 1897.
A method for use in the construction of rheostats by which the conductor is attached to the support by adhesive material which permits expansion in the conductor without serious strain to itself.

Telegraphs:—

TRANSMITTING ELECTRICAL SIGNALS. G. Marconi, London, England, 586,193. Filed December 7, 1896.
A receiver for electrical oscillations combining an imperfect electrical contact, a circuit through the contact and means actuated by the circuit for shaking the contact.

Telephones:—

SWITCHBOARD. C. E. Egan, Chicago, Ill., 586,285. Filed May 1, 1897.
Comprises a jack made flexible to permit it to be moved in effecting the electrical currents, and a drop magnet mounted upon and movable with the jack.

TELEPHONE SYSTEM. W. W. Davis, St. Louis, Mo., 586,529. Filed September 5, 1896.
Means whereby one station may communicate with another without the aid of an attendant at the central exchange.

NEWS AND NOTES

THE ELECTRICAL ENGINEER IN THE COLLEGES.

As the oldest electrical paper in the field, The Electrical Engineer has built up a very solid clientage among readers and advertisers, and stands foremost as the representative journal in the art and industry. What central stations think of it will be found in a pamphlet of opinions, which we shall be glad to send to any address on application. Below we give the opinion, bearing date June 23, 1897, of one of the leading technical teachers of the West, Prof. Edgar Kidwell, Michigan Mining School, Houghton, Mich. Note what he says:

I like the paper for the following reasons:

1. To a greater extent than any other American electrical paper I read, The Electrical Engineer is true to its name, and edited for engineers, not physicists, amateurs or electricians only.

2. In the judgment of the writer, any electrical education not founded upon sound mechanical engineering training is ill-advised. The Electrical Engineer seems to recognize this, and select its matter accordingly.

3. Higher mathematics is an excellent thing in its place, but I question whether it is good policy to load up the columns of an engineering journal with abstruse mathematical discussions on matters irrelevant to engineers—particularly controversies of no interest except to those who take part. The Electrical Engineer is happily free from such matter.

4. The paper sticks to the text—I am about tempted to call it the "Old Reliable," because it never chases out of its course to gather in a lot of popular stuff which is beautiful for padding, impressive to the general advertiser who likes bulk, catchy to the layman, but apt to make the engineer wonder what real value he is getting from his subscription.

5. Perhaps the best thing to say is that of the entries in my card index more of those frequently looked up and used come from The Electrical Engineer than from any other American electrical paper.

LAWTON, MICH.—Geo. H. Rix & Company, who have a 25 years' franchise, will have eight miles of circuit and in addition to lighting will pump water, etc. The capital is $8,000.

MECHANICAL

THE WESTINGHOUSE GAS ENGINES.

RECOGNIZING the fact that in many situations gas engines can be operated to advantage, the Westinghouse Machine Company, of Pittsburg, Pa., have just brought out a complete line of these engines ranging from 5 to 500 h. p.

In its general design these engines embody the important features which have made the Westinghouse steam engine so popular and successful; the upright self-contained construction and the self-lubricating principle being particularly apparent.

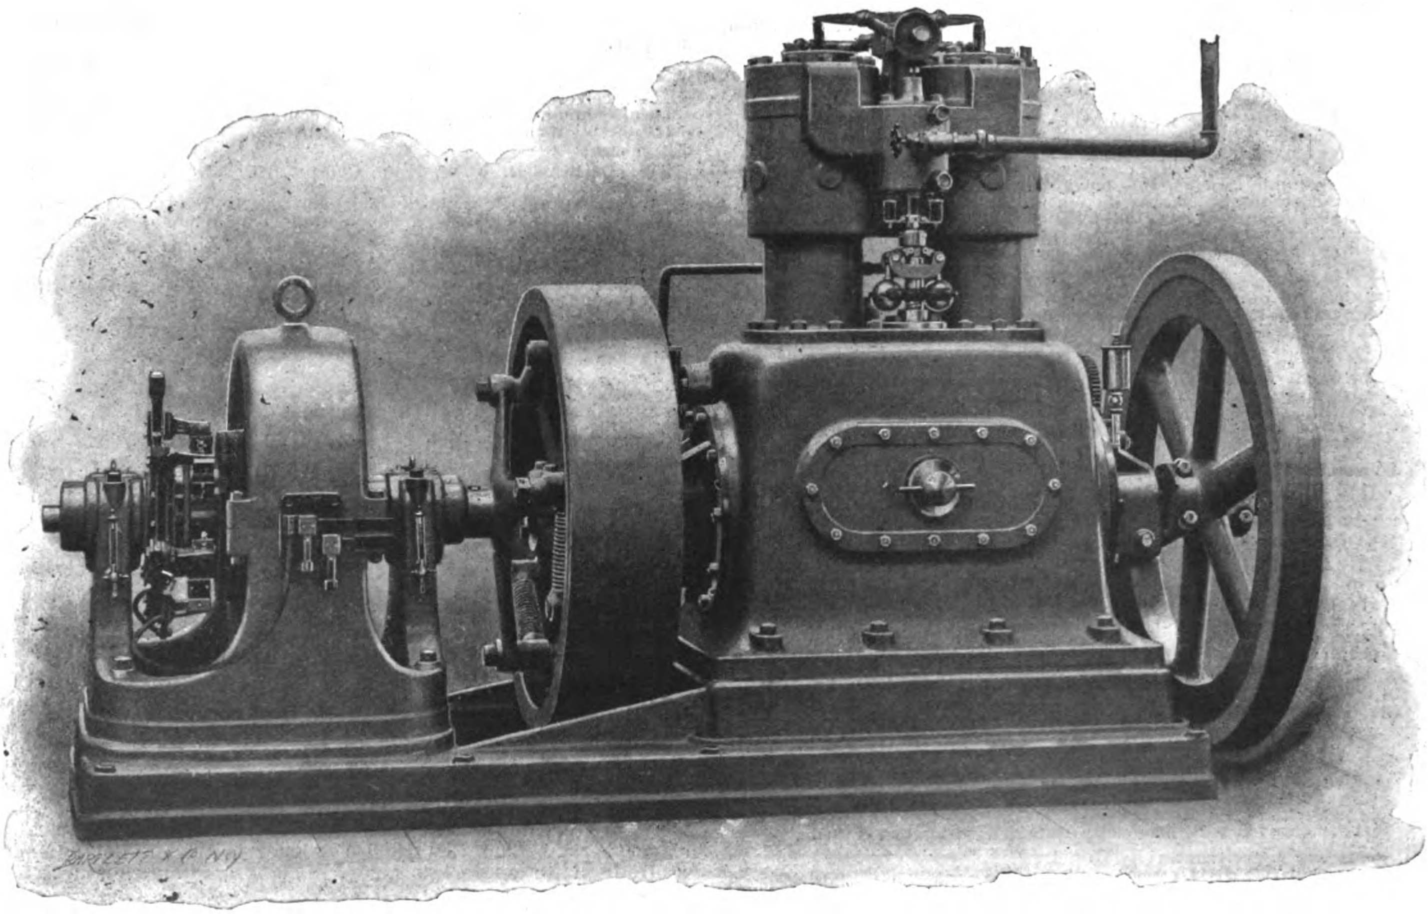
The cylinders, two in number on the smaller sizes and three on the larger sizes, are cast from a special mixture of hard, fine-grained iron, bored and finished with a high degree of accuracy. The pistons are of the trunk pattern, cast from the same quality of iron as the cylinders, made very long in order to serve the purpose of a cross-head, without causing perceptible wear on the cylinder walls. The piston is packed with cast-iron spring rings, which insures a maximum of tightness and long life. As in the Westinghouse steam engines, the piston carries a case-hardened steel wrist pin, accurately ground to size, with which the upper end of the connecting rod engages. The connecting rods are forged from steel, the ends being fitted with adjustable bronze boxes lined with the best quality of genuine babbitt metal. The adjustment of the piston end of the connecting rod, usually a difficult operation in trunk piston engines, has been taken care of in a particularly ingenious and convenient manner.

The shaft is a forging made from the best quality of open-hearth steel, the cranks being forged solid and slotted out; it is machined all over and is particularly strong and heavy.

The bearings are all adjustable, the lower halves being set up by wedges operated by screws. As the wear on the bearings is always downward, the upper halves preserve their original position. In taking up the wear, the wedges are drawn across until the shaft is brought up against the upper halves of the bearings.

The ignition of the explosive mixture is accomplished by the electric spark. The igniters are simple in construction and exceedingly durable. They are mounted in small castings, easily removed and replaced. In sizes from 15 h. p. up, there are double igniters in each cylinder. One igniter only in each cylinder is in operation at any one time, the other being held in reserve. In case of accident to the igniter in service, the battery wire can be instantly shifted to the binding post of the reserve igniter and the engine kept in service until it can conveniently be shut down for examination.

The lubrication of the main bearings is taken care of by sight feed oil cups, supplied with the regular Westinghouse crank case oil costing 15 cents per gallon at Pittsburg. The crank case is filled with water up to the division in the crank pin brasses, when the engine is on its bottom center, and a layer of crank case oil about one-half inch thick is added on top of the water. The motion of the cranks beats the oil and water into an emulsion, which is thrown over the internal working parts, lubricating them copiously and thoroughly. When the engine is once started, there is enough surplus oil from the main bearings passing into the crank case to keep up the supply. A gauge glass on the back of the crank case always indicates the proper height of the oil and water.



WESTINGHOUSE GAS ENGINE.

The governor and valve mechanism are lubricated by a small amount of any good quality of engine oil, fed by sight feed cups. No cylinder oil whatever is required. The piston coming in contact with the oil thrown against the lower end of the cylinder walls, carries up the small quantity of oil necessary to keep the pistons and cylinders in good condition.

With the engines which are too large to be readily started by hand there is furnished a simple and effective air compressor and an air storage tank of ample capacity. The air compressor can be operated by hand to charge the tank for the first time, after which it is run by a belt from any convenient pulley either on the engine itself or on the shafting. By running the compressor a few minutes every day the tank is kept fully charged and ready for starting the engine at any time. In starting, one cylinder of the engine is converted into a compressed air motor, without disturbing the functions of the other cylinder or cylinders. The engine being set with the crank a little past its upper center, the air and gas inlet valves properly adjusted, and the stop valve on the air tank opened, it starts up and continues to run on the air pressure until explosion takes place in the other cylinder. The stop valve is

then closed, the inlet and exhaust valves set again to work in the regular manner, and the engine is in full operation. Three or four revolutions with the air pressure are generally sufficient, the process being strictly automatic, requiring no manual dexterity on the part of the operator, and consuming less time than it takes to describe it. The Westinghouse gas engines, as do all gas engines which have achieved any marked degree of success, operate on the plan proposed by M. Beau de Rochas, popularly known as the Otto cycle.

By the use of two cylinders alternating the working strokes of the pistons, the Westinghouse gas engine receives an impulse at every revolution. A sensitive governor regulates the amount of the explosive mixture admitted for each charge, in proportion to the load on the engine, giving an impulse at every revolution whether running fully loaded or entirely light. On this account, for smooth running and steady speed, it is claimed to be equaled only by the best steam engines, and these essential and desirable qualities are obtained without overloading the shaft with heavy flywheels. The engine is therefore claimed to be specially suitable for electric lighting work.

For the Westinghouse gas engines there has been established a commercial rating which bears about the same relation to the ultimate brake horse power as the rated power of the steam engine bears to its ultimate capacity; that is to say, the rating represents about 80 to 85 per cent. of the total maximum brake horse power developed on the test. This enables the engine to take care of occasional overloads, to compensate for the various qualities of gas met with in practice, and does not compel the purchaser to forget all his settled ideas as to what constitutes a commercial horse-power in a motor of any sort.

MR. C. W. SPEAR has been appointed the receiver to wind up the affairs of the Swan Incandescent Electric Light Company, which is going out of business, with $6,903 assets and no liabilities.

TRADE NOTES & NOVELTIES

THE CONSOLIDATION OF A. K. WARREN & CO. AND THE ELECTRICAL MAINTENANCE CO.

We have to report the union of two well known industries, viz., that of A. K. Warren & Co., of 451-453 Greenwich street, New York City, the old-established emergency and repair house of New York and the surrounding districts, and the Electrical Maintenance Company, late of 50 Broadway.

The consolidation of the two interests into one business has formed a substantial concern, with branches in Boston, Philadelphia, and Baltimore, so that in conjunction with the large trade which was heretofore profitably enjoyed by A. K. Warren & Co., it is now augmented by between five and six hundred maintenance contracts, transferred by the Electrical Maintenance Company on consolidation.

VIEW IN ARMATURE WINDING DEPARTMENT, SHOPS OF AMERICAN ELECTRICAL MAINTENANCE CO.

It was wisely decided by the various heads of the two companies interested that a change of name would be beneficial, and they decided upon calling the consolidated concerns "The American Electrical and Maintenance Company," retaining as a trade-mark the well known white Swiss cross adopted by the former firm some years ago.

The field of the business established by these two companies covers maintenance by contract, repairs in general and emergency work in particular, and wiring supplies of every description, so that after the contractor has installed a plant, wheresoever it may be, the only way the proprietor can guarantee a certain expense per annum is by taking a contract to cover all losses by damage, both large and small, to his electrical machinery. The importance of this is demonstrated by the number of contracts that have been written in-

dividually by these two concerns in different branches in the past two years, the field being thoroughly worked by an efficient corps of agents. The results have proved the establishment of an entirely new business in the electrical field.

With the extensive repair shops that this concern now have they are able to undertake repairs to any style, class or size of machine used, and with their branches throughout the United States, they will be able hereafter to minimize the expense of running an electric plant and the danger of its shutting down at times (as is often the case) when it is most needed. The shops are open day and night, and are at the call of all users of electricity, either for light or for power, and a large force of expert electricians and mechanics is at instant call for those who need them.

The directors and stockholders of the American Electrical and Maintenance Company are men well known in the electrical business. The engineering department of this company is under the superintendence of Mr. A. K. Warren, whose ability and indefatigable zeal in emergency matters are well known to most of the electric light stations and isolated plants within one hundred miles of the "Empire City." The financial part of the business is conducted by Mr. James Rich Steers, formerly Mr. Warren's partner in the firm of A. K. Warren & Co., and the entire general management of the enterprise is in the hands of Mr. George Stanmore, late general manager of the same firm.

The board of directors comprises the following well known, substantial gentlemen: A. K. Warren, E. R. Johnes, G. Harvey Cook, Henry B. Wilson, William Duryea, J. R. Steers and George Stanmore, New York; Henry A. Root and G. Arthur Hilton, Boston.

The home office of this undertaking is 451-453 Greenwich street, New York City, and the facilities for handling their class of work are amply exemplified in the illustrations in the new catalogue issued by this company, which will be sent free for the asking.

The executive officers court inquiry and investigation of all their methods and means for taking charge of plants or arranging for immediate repairs on all classes of mechanical or electrical appliances.

In addition to the above they are arranging a system for the exchange or handling of second-hand apparatus, which at the present time it is difficult to obtain except by costly advertising and personal investigation, and the methods employed will give the purchasers or parties wishing to sell different styles of apparatus facilities for transacting the sale or purchase at far less than heretofore.

It may be well to mention that this business was started about five yeas ago, with a small shop employing about five men. It has now a pay roll list of about one hundred and twenty men on repair and emergency work alone, thus showing the rapid growth and the public's appreciation of an industry that becomes yearly more a necessity owing to the general use of electricity.

CENTRAL ELECTRIC CO.

The Central Electric Company, of Chicago, feel that there is nothing more inspiring than to be congratulated by their patrons, upon satisfactory material, and pleasing shipments. They state that they are constantly receiving congratulatory letters and verbal approbations from their numerous friends and customers. As evidence of the success with which their railway materials are meeting, the following is quoted, as having been received from one of their best customers, which is direct evidence of their faculties for pleasing:

"Central Electric Company, Chicago, Ill.

Gentlemen:—

We have just completed eighteen (18) miles of electric railway, using your material for the entire overhead construction. We have found everything to be first-class and can recommend your materials for the purposes for which we used them. The shipments have all been made very promptly.

Yours truly,

President and General Manager."

ADVERTISERS' HINTS

THE MONSON-BURMAH SLATE COMPANY, Portland, Me., are making a specialty of slate for electrical work, both plain and ebonized, for switchboards, etc. Many leading manufacturers after using specimens of the slate are now continuing it in preference to any other.

THE GENERAL ELECTRIC COMPANY illustrate the "Type H" transformer of which they are building a complete line with capacities varying from 600 to 30,000 watts, and also publish a table showing the satisfactory results obtained by their use.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, have appointed Messrs. Sargent & Lundy, Monadnock Building, as their general sales agents in Chicago. Messrs. Sheehan and Hewitt, 14 South Water street, Newburg, N. Y., will take care of their interests in central, northern and western New York.

WALLACE BARNES, Bristol, Conn., supplies springs of every description for use in the construction of machinery and instruments.

ELECTRIC LIGHTING

MOORE LATEST VACUUM TUBE LIGHTING APPARATUS.

WHEN Mr. D. McFarlan Moore, after a long period of study, came to the conclusion several years ago that the solution of the vacuum tube lighting problem lay in breaking an inductive circuit in a vacuum, he almost immediately decided that it could be done most advantageously by the use of a rotary motion—not a vibratory motion. But he also realized that mechanically a vibratory motion was far easier to construct in a vacuum than a rotary one and that the vibratory motion in the form of his vacuum vibrators would have a large field of usefulness and, since immediate results were very much desired, he decided to demonstrate the feasibility and practicability of the vacuum break by means of the vibrator, and he therefore perfected that device first.

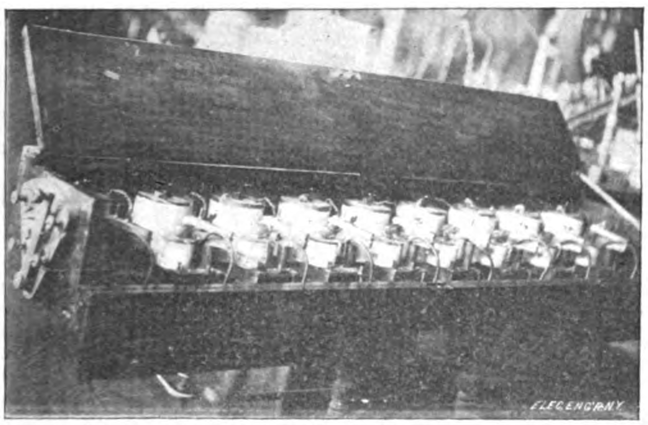

FIG. 1.—MOORE VIBRATORS.

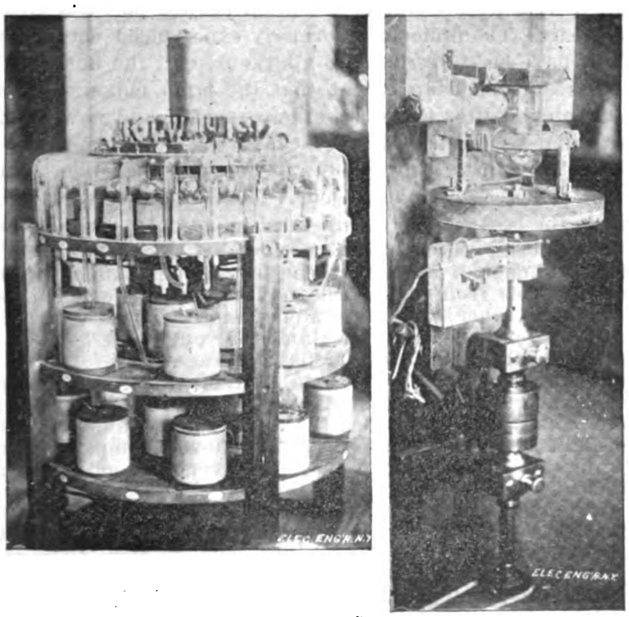

FIGS. 2 AND 3.

The accompanying illustrations show the various stages of his apparatus due to this decision. Fig. 1 shows one of the three boxes 4 feet 6 inches by 14 inches by 10 inches, which contained nine vibrators each and which were used by Mr. Moore in lighting the hall of the American Institute of Electrical Engineers, the first hall in the world to be so lighted. Our readers will also recall Mr. Moore's lighting the stage on the occasion of his lecture before the N. E. L. A., and, finally, his exhibit at the Electrical Exposition in New York, during May, 1896, at the Grand Central Palace, which was viewed by 85,000 people.

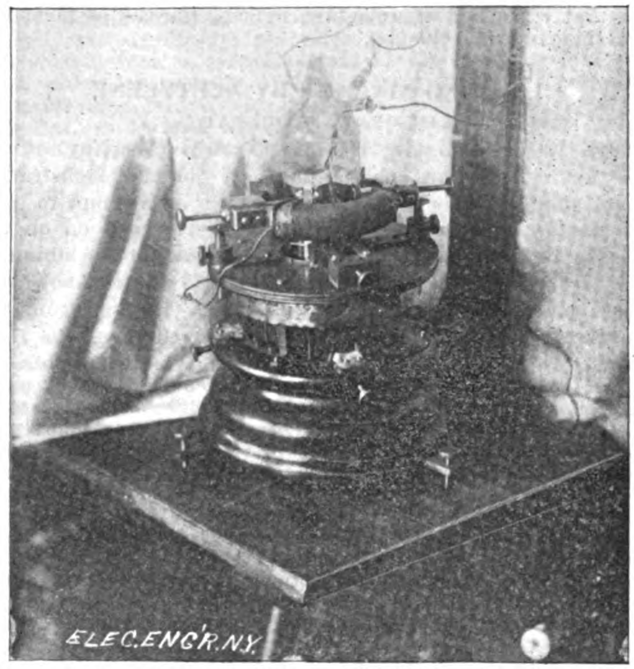

FIG. 4.—MOORE ROTATOR VACUUM BREAK.

Fig. 2 shows the next piece of apparatus constructed by Moore, in which the vibrators are arranged in the form of a cylinder instead of in long boxes. This piece of apparatus lighted the entire Moore laboratory for several months last fall. Fig. 3 shows one of the early forms of rotators, which was also used to light the laboratory.

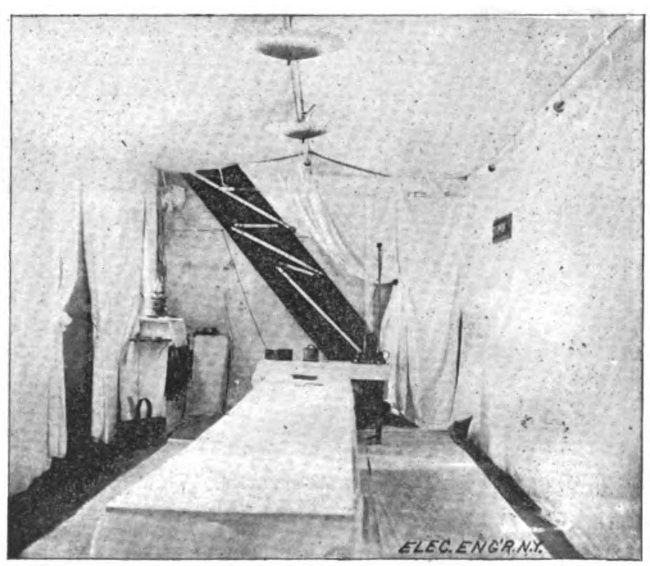

FIG. 5.—ROOM LIGHTED BY MOORE VACUUM TUBES.

Fig. 4 shows a beautiful piece of apparatus, the finished rotator which was used to light the hall at the Moore laboratory during the entire evening of his last exhibit, on May 27, 1897.

Seventy-five people sat in a room 11½ by 34 feet under the perfectly steady rays of vacuum tubes for two and one-half hours, and were there photographed. Fig. 5 shows the interior of the room. It will be noticed that the tubes are hung near the junction of the ceiling and wall at about the place usually occupied by a picture moulding.

By way of diversion Mr. Moore entertained his visitors by showing them a number of interesting experiments. A lightning flash and giant candlestick are shown in the illustration, as well as one of the signs on the wall.

Mr. Moore informs us that it will not be long before he will be able to show still further advances of a pronounced character, that will place vacuum tube lighting abreast of incandescent lighting, in economy.

LIGHTING NIAGARA BY ACETYLENE.

BY ORRIN E. DUNLAP.

THE Acetylene Light, Heat and Power Company, of Niagara Falls, are making the first public demonstration of the illuminating powers of their gas in an attempt to light the great cataract. The lights were first turned on on the evening of Thursday, July 16. For the present the illumination is confined to the American Fall and the rapids of the upper river above and below the bridge leading from the mainland to Bath Island, generally referred to as the Goat Island bridge. In all, fifteen large locomotive headlights are in use, and eleven of them have seven burners each, while the remaining four have five burners. These burners are of the Naphey pattern, and consume one-half foot an hour.

Six headlights have been placed on the Goat Island bridge, three on the upper and three on the lower side, while others have been placed in Prospect Park, and four below the high bank on the debris slope. The lamps on the upper side of the Goat Island bridge throw their beams on the water as it comes tumbling down from reef to reef, and the lights on the lower side gleam across the dancing waters as they speed onward toward the brink of the American Fall, their plunge over the magnificent precipice being illuminated by the lights in Prospect Park. As the waters tumble on the rocks below and send up a spray cloud the beams of the lights below pierce the mist and make a beautiful sight.

The expanse of the river just above and at the brink of the American Fall is very great, and this extent of space makes the lights appear as having no great penetrating powers, whereas the fact is that they are quite strong, but the apparatus in which they are fitted is hardly the thing to show them off in all their brilliancy. Then, again, the plant was installed with considerable haste, in order that it might be in operation on the occasion of the recent visit of the Pan-Americans. One thing fully made clear by the demonstration is that

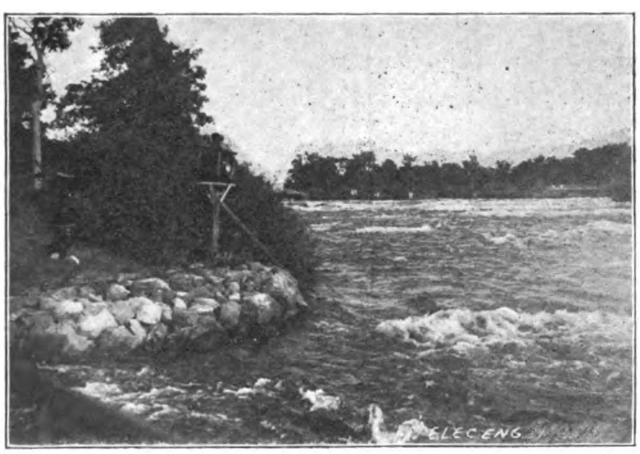

FIG. 1.—LIGHTING NIAGARA BY ACETYLENE. VIEW OF THE RIVER FROM PROSPECT POINT.

Manager Devine, of the Acetylene Light, Heat and Power Company, is a hustler of no small degree, for he had the entire equipment installed in a very few days.

The gas is supplied to the lights from three Naphey automatic generators, each of 250 pounds' capacity. One of these generators is placed in the inclined railway building adjoining Superintendent Welch's office; another in what is known as the lower park office, and the third in a small building on Bath Island. From the generators half-inch pipe runs to the lights, and a large amount of this pipe was necessarily laid, the Oliver Company having the contract. All the pipe is carefully concealed beneath the sod or under the bridge.

This is not the first time the falls have been illuminated. In 1879, when electric lights were somewhat of a novelty, the park was owned by a private company who had the enterprise to purchase a Brush generator to supply eighteen lights, but after a few nights' trial it was found that its capacity was not large enough, and the company exchanged their generator for one of larger capacity. With this outfit the Falls,

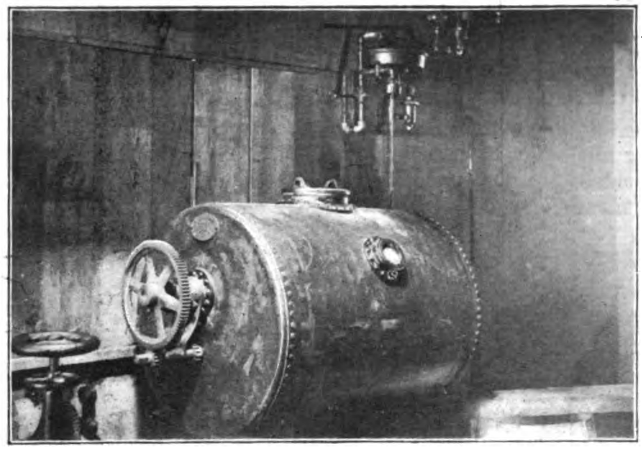

FIG. 2.—THE ACETYLENE GENERATOR.

park and gorge were nicely lighted, and in one summer over 150 excursions came to the Falls at night to see the illumination. Every night the park was crowded, and not the least beautiful effect was the light thrown on the fountains through colored glass. When the State of New York took the park and opened it free to all mankind forever, the electric light plant was sold, and since then the great cataract has been shrouded in the darkness of night, much to the regret of the residents and visitors, for Niagara at its best is lacking in evening attractions, and the lights on the Falls served to aid in passing the evening. For this reason the acetylene illumination will be popular with all.

"220 VOLT LAMPS."[1]

By PROF. G. D. SHEPARDSON.

THE high voltage incandescent lamp has been attracting an increasing amount of attention during the past four or five years. The difficulties formerly experienced with 220-volt lamps have been overcome to a large extent; the business has increased to such an extent that the lamp makers can sort their lamps better to supply orders exactly, and now the 220-volt lamp seems to be in the field to stay. Reports from the plants are almost invariably encouraging, whether coming from manager or from patrons. Their common verdict that this is the best system extant must be accepted as proof positive of good, reliable service and of a good reputation at home, although it must be borne in mind that much of their praise comes from those who have had little or no experience with other modern systems and who also naturally stand up for home industries and for "our plant." Even the reports from engineers who have changed from 110 to 220 volts must be taken with some caution. For example, from one of the large English plants that has recently changed over, comes the report that the new 220-volt lamps give better light with less watts than the 110-volt lamps displaced. But by test the 110-volt lamps were of very low efficiency, and old at that.

The advantages of using higher voltages are well understood by engineers. It is commonly understood that 125-volt systems cannot economically serve districts more than about 1,000 feet distant. For larger districts the three-wire and alternating systems have had the field to themselves. But the low, all-day efficiency of the alternating system, when used for scattered lighting, and the exclusive control claimed over the three-wire system, have driven the independent manufacturers to the high voltage lamp as the only practical means of competing for such business. The 220-volt lamp has been so successful for lighting villages and small cities that the

[1]Read before the Northwestern Electrical Assoc.—Abstract.

alternating system seems to have given way and almost all of the new plants in such places now adopt the 220-volt direct current system, where a few years ago alternating systems had the field almost to themselves. The companies using the three-wire systems also find in the 220-volt lamp the possibility of extending their lines to outlying districts and of operating motors at 440 volts directly from the outside mains of the lighting service, instead of requiring special 500-volt generators and power circuits.

It is urged against the 220-volt lamp that it is of lower efficiency than the 110-volt lamp, so that the power plant must be larger to supply an equal amount of light. The larger item of interest on first cost of power plant and larger fuel

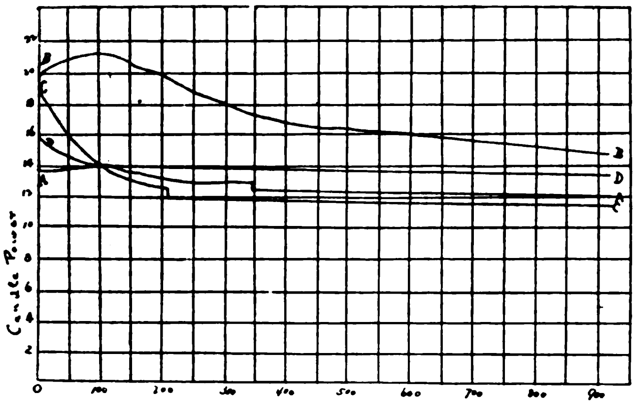

FIG. 1.

account may more than offset the saving in cost of copper if calculated for the same percentage loss. The 220-volt lamps also cost more than the 110-volt, but this is unimportant, since the first cost of an incandescent lamp is only a small fraction of the value of the current used during its lifetime. Again, the average life of the low efficiency 220-volt lamp seems to be longer than that of the higher efficiency 110-volt lamp, so that the cost of renewals may even be in favor of the 220-volt lamp. The economy of copper is even greater than indicated by the foregoing discussion.

Lamp makers advise the operation of lamps at high efficiency only when the regulation is close, and they advise low efficiency lamps for use where the voltage fluctuates considerably. The 220-volt lamp cannot be made with as high efficiency combined with reasonable life as can the 110-volt lamp of equal candle-power, on account of the smaller diameter and greater length of the filament. When operating at high efficiency, the temperature of the filament is higher and the filament is, therefore, softer, less rigid and mechanically weaker.

The necessarily lower efficiency of the higher voltage lamp is not an unmixed evil. For, since its efficiency is low, the allowable variation of voltage is greatly increased. Consequently, if two systems, one for 110 volts and one for 220, be laid out for equal percentage variation of voltage, the variation of the light from the 220-volt lamps will be hardly noticeable when that of the higher efficiency of 110-volt lamp will be intolerable. From this it follows further that if the two systems be laid out for equal fluctuation of light, the 220-volt system will allow much greater percentage range of voltage and require correspondingly less investment in copper. The conclusion is, therefore, reached that the 220-volt system requires considerably less than one-fourth the weight of copper required by the 110-volt system for serving the same district with equal satisfaction to users. When it is considered that the cost of the feeders and mains often equals or exceeds the entire cost of the station equipment, it appears that the great saving in copper easily balances the increased cost of the larger generating plant and of the larger amount of fuel.

In order to obtain accurate and reliable data concerning various 220-volt lamps on the market, new lamps were secured from the regular stock of several lighting plants in Minnesota, representing the regular output of three different manufacturers as furnished to regular customers. Samples were obtained directly from another manufacturer for test purposes. Lamps were ordered from a fifth factory, which claimed extraordinary results, but they declined to furnish the lamps ostensibly on the plea of being behind their orders owing to an unusual rush of business.

Arrangements were made for a life and efficiency test of the various lamps. By the courtesy of the Minneapolis General Electric Company, current at 220 volts was obtained from the outside mains of the Edison three-wire system. The city gas inspector allowed the use of his photometer room which was connected with the three-wire street mains at a point about 2,000 feet from the station and where the voltage fluctuated as much as at any part of the system. The measurements were made by O. G. F. Markhus and W. A. Myers, fourth year students in electrical engineering at the University of Minnesota. The results are exhibited in the accompanying curves, Figs. 1 and 2. The various makes of lamps are marked A, B, C and D. One lamp each of A and C groups was found to be very poor, while the others agreed quite closely.

The record of breakage is somewhat interesting. Twelve lamps of make marked D were obtained from the factory, six directly and six through an agent. Four broke in transit, two exploded as soon as connected into circuit. Of the two placed with globes horizontally, the one having the plane of the filament at base in the vertical position lasted throughout the life test, while with the one with plane of filament in the horizontal position the filament drooped in 159 hours so far as to touch the globe and crack it. The filament of the corresponding lamp of group C drooped and broke the globe in 215 hours. The corresponding lamp of group D broke in the same way in 315 hours. The anchor in the horizontal lamp of group A, having the plane of shank vertical, broke and allowed the filament to touch and break the globe after 345 hours. With these exceptions all the lamps were in fair condition at the end of 920 hours when the test closed. The conclusions seem to be that if the lamp is hung vertically it will last 1,000 hours or more if it lasts ten minutes. If the lamp must be placed horizontally, the shank of the filament should be vertical rather than horizontal. It is also suggested that the size of globes might be increased with advantage.

As a matter of general interest a new lamp of each group was subjected to a breaking test. The following table shows great variety both in the toughness of the filaments and also in the change of resistance:

Lamp.	Voltage.	Amperes.	Lamp Broke, Seconds.
A	316	1.05	31
B	300	.78	30
C	447	.85	40
D	378	1.10	31

The lamp tests here presented are offered not as an exhaustive research covering all suggested or possible problems connected with the performance of high voltage incandescent lamps, but simply as a modest contribution to the literature of the subject.

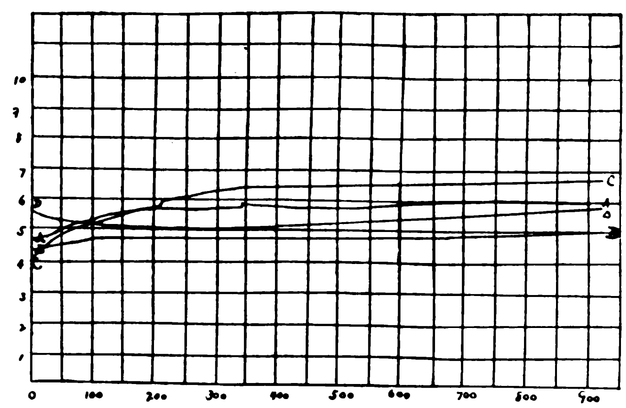

FIG. 2.

In closing, I will submit some reports recently obtained from a few of the 220-volt municipal plants in Minnesota, which were kindly placed at my disposal by W. I. Gray & Co., of Minneapolis.

Copy of reports received from 220-volt plants at Adrian, Wells, Lake City and Windom, Minn.

ADRIAN.—The electric light plant consists of an 80 h. p. high speed engine made by Ball Engine Company and a 55 k. w. dynamo made by Siemens & Halske Company. Plant has operated two years with entire satisfaction. Make of arc lamps used, Manhattan; make of incandescent lamps, Edison; average of incandescent lamp life, about 600 hours; number of arc lamps for street lighting, 12; number of arc lamps used for inside lighting, none; number of incandescent lights used in stores, 480 16 c. p.; number of incandescent lights used in residences, 110 16 c. p.; cost of incandescent lights, 16 c. p.,

per month, in stores, 45 cents; cost of 16 c. p. incandescent lamps in residences, per month, 45 cents, 10 o'clock circuit; 55 cents, 11 o'clock; 65 cents, 12 o'clock. How many hours a day does plant run at this season of the year (January, 1897)? Six hours. Meter rate to consumers, 8½ cents per 1,000 watts; income from the plant, per month, $185; expenses of operation, per month, $195; amount of (Youghiogheny) coal used last month, about 19 tons.

(Signed) G. A. SANDS, Recorder.

Water-works and electric lights operated from same plant at Adrian.

WELLS.—The electric light plant consists of an 80 h. p. engine made by Ball Engine Company, and a 50 k. w. dynamo made by the General Electric Company. The plant has operated two years with good satisfaction. Make of arc lamps used, Thomson, '93, and Manhattan; make of incandescent lamps used, Edison; average life of incandescent lamps, 600 hours; number of arc lamps used for street lighting, 6; number of arc lamps used for inside lighting, 16; number and candle-power of incandescent lights used for street lighting, 25; number of incandescent lamps used in stores and residences, 900 16 c. p.; cost of 16 c. p. lamp, per month, in stores, 50 cents, 10 o'clock; 12 o'clock, 65 cents; residence lights all on meters; meter rate to customers, 10 cents per 1,000 watt hours; average load, 125 amperes; largest load, 196 amperes; income from plant, per month, $300; average expenses, $300; amount of Wilmington coal used last month, 45 tons—February, 1897. (Signed) A. JOHNSON, Supt.

LAKE CITY, MINN.—The electric light plant at Lake City consists of a 125 h. p. Ball & Wood engine, a 40 k. w., 220-volt dynamo, made by the Commercial Electric Company, and one 75-light Excelsior arc dynamo. The plant has operated for one and one-half years with entire satisfaction. Make of incandescent lamps used, Edison; number of arc lamps on streets, 45; number of arc lamps for inside lighting, 11; number of incandescent lamps for inside lighting, stores and residences, 850; cost of 16 c. p. lamp, per month, in stores and residences, 40 cents, 9:30 o'clock; 50 cents, 11:30 o'clock; largest load in amperes, 115. How many hours per day does the plant run at this season of the year? Eight. Meter rate to consumers, 10 cents per 1,000 watt hours; income from plant, per month, $225. Dated March, 1897.

WINDOM, MINN.—The electric light plant at Windom, Minn., consists of an 80 h. p. high speed engine, made by A. L. Ide & Son, and a 60 k. w., 220-volt dynamo, made by the Western Electric Company. The plant has operated one year with good satisfaction. Make of arc lamp used, Western Electric Company; make of incandescent lamps, Edison; average life of incandescent lamps, 400 hours; number of arc lamps used for street lighting, 4; number of arc lamps used for inside lighting, 18 Manhattan; number of incandescent lamps used for street lighting, 40; number of incandescent lamps used in stores and residences, 700; cost of one 16 c. p. incandescent lamp, per month, 4 and over, 45 cents; average load in amperes, 150; largest load, 210 amperes; meter rate to customers, 10 cents per 1,000 watt hours; income from plant, per month, $225; expenses of operation, per month, $165; amount of coal used last month, 38 tons—February, 1897.

(Signed) A. WOOLSON, Supt.

The above are all municipal plants owned and operated by the cities.

ELECTRIC METERING FROM THE STATION STANDPOINT.[1]—I.

BY CARYL D. HASKINS.

It is a well established fact to-day, well borne out by data from widely separated portions of the country, that the average electric lighting station can do one-third more business with the same station capacity on a meter basis, than it could upon a contract basis, under what were nominally equivalent contract rates, netting at the same time the same revenue per light as formerly. In other words, it is apparently well established that 33⅓ per cent. represents the average wastefulness of average human nature in connection with the use of light.

In response to an inquiry as to what merits in a meter are necessary to success, a common reply is, accuracy, durability, registration in a simple unit easily comprehended by the customer, and ability to withstand tampering. These points are probably of importance in about the sequence in which they are commonly stated; but they are too sweeping, too entirely generic and too slightly specific to be in any high degree helpful.

Let us, for example, consider the broad question of accuracy. A meter, which will be accurate under commercial conditions from quarter load to full load within 1-10th of 1 per cent., or a meter which will start on 1 per cent. of its rated capacity, are neither of them necessarily either the most accurate or the best for general commercial use. I am perfectly safe in saying, that a meter which will run within 5 per cent. of zero error on 5 per cent. of its rated capacity may readily be a much better meter, even though it will not run at all on 1 per cent. of its rated capacity, than one which will run on 1 per cent. of its rated capacity, but in regard to which no evidence is at hand as to its percentage of accuracy at reasonably low loads.

In considering the question of accuracy, therefore, the first two steps should be to determine the accuracy of the meter by actual measurements at full and medium load; and also at a reasonably low load; say, for example, 5 per cent. of the meter's rating.

One point which is very commonly neglected, but which is, nevertheless, quite essential, is the ability of a meter to give accurate results for brief periods on overloads. This is a point at which many meters fail, and is also a point which, odd as it may seem, is intimately related to light load accuracy. It may be laid down as a rule that in station operation the smallest meter which will do the work should always be used. Otherwise, however good the meter on light loads, much of the light load revenue must be lost in the effort to take care of occasional heavy loads. Extremely heavy loads are generally of brief duration, and on these loads a meter should operate with accuracy and also without injury to itself. This, therefore, should be an early point of investigation in selecting a meter.

On alternating circuits, inductive loads are becoming commoner every day. The wider use of fan motors and other alternating power devices, the rapidly growing popularity of alternating circuit arc lamps, and the commoner use of inductive dimmers, all render it essential that a meter should be accurate irrespective of the power factor. The company which insists upon charging its patrons for power delivered to fan motors on a basis of volt amperes, is obviously rendering itself unpopular, greatly limiting its business and giving its competitor, or competitors, the best of opportunity for intruding; yet, many such companies exist to-day, and they exist not because they are following a wise policy in their own estimation, but because they are ignorant of what they should look for in the meter which they are using.

Again, there are few electric light stations to-day of any considerable size and age which are not operating some smooth core and some tooth core alternating armatures. It is, therefore, important that the meters in service at such stations should be equally accurate on any shape of wave. This same consideration holds good in connection with frequency.

Even after this long list of points which must be investigated, as contributing to the broad question of accuracy, there are others which also merit consideration, but to a less degree. Such, for example, as barometric conditions (more especially altitude), temperature and humidity. These all have direct bearing upon the question and all enter into the every day conditions of central station practice.

The second point, which is commonly given consideration in the selection of a meter, is that of life. This is a question which must depend more upon good judgment than upon any test which can be applied..

Ninety per cent. of all the wear in a meter, centers in the case of motor meters at the single jewel bearing, which is almost universal. The two chief factors which have influence upon the mere mechanical life are the weight of the moving mechanism, and its speed, the variation of the area of the point of contact being, of course, always so small as to be out of the consideration.

Practice has indicated that low speed is more conducive to long life than is light weight of the moving mechanism, although both are, of course, very important. More important than either, however, is the quality of the material used at the points of friction and the ease with which the friction parts can be renewed. The best of sapphire is barely good enough, and the pivot end must be of correct shape, burnished to the highest degree, and its point must be absolutely concentric with the center of movement.

More than half of the meter jewels which are destroyed are rendered useless, not by the rotary motion of the shaft, but by reciprocating motion of the shaft, due to vibration. Hence it is very necessary that the jewels should be in some way cushioned, for vibration cannot be always avoided.

[1]Read before the Amer. Inst. Elec. Engrs. Abstract.

A NEW FORM OF INDUCTION COIL.[1]

BY ELIHU THOMSON.

THE induction coil presently to be described, it is believed constitutes a new type employing the principle of a "substitute primary" or "secondary primary," which principle has been applied by me in a variety of ways.

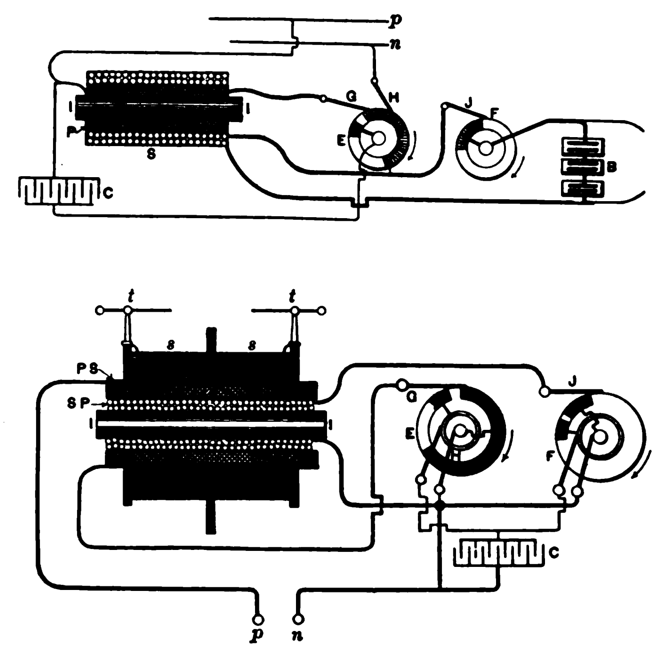
The prime object of this coil is to permit the direct connection to circuits of considerable potential for obtaining energy for the production of high potential discharges, like those of a Ruhmkorff coil for working Röntgen ray vacuum tubes, and for such like purposes. The object, also, was to avoid the employment of banks of lamps or storage batteries, and to limit the energy consumed to only that amount required to work the coil itself. Furthermore, no larger condensers than those ordinarily used with an induction coil of equal capacity are needed, and no air blast, while the coil as a whole is still available as an ordinary Ruhmkorff without change in its structure or connections.

To illustrate the principle, reference is made to Fig. 1, where p n represent connections to mains at, say, 110 volts difference of potential; I I is an iron wire core around which are wound two coils, one over the other, either of which may, of course, be the primary. The inner coil, P, in the figure is made the primary, and is wound with many turns of comparatively fine wire. For 110 volts it may have some thousands of turns and be wound with a wire safe for .5 to .75 ampere. The outside wire, S, may be coarse or fine. In the figure it is quite coarse and of relatively few turns, since it is assumed to give low potential and large current. The coil, S, is so proportioned as to be practically almost short-circuited at intervals by its load at B, which is three cells of storage battery in series, for example. The object is assumed to be that the batteries are charged by transference of energy from coil, P, to S at low potential in S. The coil, S, should have ample copper so as to lower its internal resistance as much as possible; the resistance of the cells, B, should be low; and the average voltage of discharge of S much superior to the counter e. m. f. of B. Two synchronously revolving break-pieces, E, F, which may, in fact, be combined into one, are used; E is for governing the intervals of passage of current in coil, P, and connection of condenser, C, across the break or interruption periodically made between one terminal of P by a brush, G, and a metallic segment on E occupying a considerable arc on its periphery. Brush, H, connects to main, n. Back of the main segment on E is a small condenser segment in continuous connection with one side or foil of the condenser, and the other side is connected to the other terminal of P, or that leading direct from line, p. The contact maker and breaker, F, has a segment which is in continuous connection with one terminal of battery, B, to be charged and which touches a stationary brush, J, at or about the time of the break between brush, G, on the main segment of E. The battery, B, may have terminals by which it may furnish current while being charged.

Now let the break wheels, E and F, be given rapid revolution, say, 10, 20 or 30 per second. The contact of brushes, G and H, with the main segment of E passes current for a certain considerable fraction of the revolution, at full line potential of 110 volts, through primary, P. The current rises gradually during this period, and may at the end attain a value of one ampere, more or less. With slow revolution it would be limited by the resistance of P chiefly, but at rapid rates, the time constant of P acting as a self-induction, determines the ultimate value of current before breaking. Upon the break of brush, G, with the main segment, it touches the condenser segment which is thereby put across the break, but the circuit of S is also closed by contact of segment on F with brush, J. The condenser receives only a small charge on account of the circuit of S having been closed. In fact, the break at G with main segment of E would be nearly sparkless without the condenser, C, but what slight self-induction is not wiped out by the mutual induction of the currents in S and P is very easily taken care of.

The magnetizing of the core, I I, or absorption of energy is by P, while delivery of energy is by S acting as if nearly on a closed circuit. This condition, however, does not involve much waste of energy if the ohmic resistance of the circuit of S be low enough. Here, then, is a transfer of energy from one circuit to another while the currents are direct currents in each circuit. To insure this being the case in S, the time of contact of segment on F with brush, J, must be selected so as not to permit any reversal, i. e., the break of said segment with K must be timed to be made on the cessation of the first impulse or discharge from S. To do this an ammeter, responding to direct currents only, placed in the battery circuit, or in the leads from S, will indicate a maximum direct current when the segment, F, is of proper extent, and less under other conditions.

With the principles of the above apparatus in mind, it is easy to understand the action of my new form of induction coil, which may be described, briefly, as follows. The iron core, I, Fig. 2, of the induction coil, is wound with the ordinary coarse primary coil and terminals provided therefor. Then a coil of intermediate gauge, between the inner primary and the outer secondary, is wound. It is to be capable of being connected across a circuit of 110 volts as with coil, P, Fig. 1. This coil is the true primary or energy supplying coil, but for convenience and saving of wire I prefer to connect it in as the under portion of the real secondary circuit. It thus becomes useful as a part of the secondary itself and having several thousand turns, adds a considerable fraction to the total potential of the secondary. The secondary is ,as



FIGS. 1 AND 2.

usual, of quite fine wire of many thousands of turns, well insulated throughout.

In Fig. 2, the coarse coil is marked S P, and the intermediate coil, P S, while that outside is marked S. The functions of the coils, S P and P S, are to act as secondaries and primaries alternately. This is, in fact, an essential function of S P, but is only incidental to coil, PS, having been connected into the secondary circuit, S, whose terminals are at t t. The break-wheels, E F, are like those of Fig. 1, except that in F there is a much shorter main segment and a condenser segment following, as in E. There is no battery in the circuit of S P, but it is put on dead short circuit at intervals, just at the time P S is broken. Coil, P S, receives current from line at p n, at 100 to 200 volts, or more. On the break of this circuit at brush, G, the ampere turns, so to speak, are shifted suddenly into circuit of S P, closed on itself by J F. The consequence is that even at slow breaks no spark occurs at the rupture of G E. As soon as the current has been fully established in S P on short circuit, and after brush, Q, has got entirely away from all metallic connections on E, the main segment of F breaks the circuit of S P which is conveying a very heavy current at low potential. The condenser, C, is put instantly across the break, and the spark flies between terminals, t t. In this way a coil of the size of a 6-inch Ruhmkorff, gives a torrent of 6-inch sparks with an average current from a 110-volt line of about one-half an ampere. A simple motor or clockwork may be used to drive the break-wheels, E F, which are made of fair diameter to insure accuracy in operation. The best results are only to be

[1]Read before the Amer. Inst. Elec. Engrs.

obtained when the proportioning of the parts is carefully done, and with a knowledge of the result to be obtained.

The discharges are indistinguishable from those of a similar Ruhmkorff. In fact, the coil described might be used with the same condenser, C, as an ordinary Ruhmkorff coil energized by batteries. In this case the terminals of the coil section, P S, are disconnected, brush, J, lifted and battery inserted between brush, G, and terminal of S P, which goes to J in Fig. 2. The break-wheel, E or F, when run with low potentials may be immersed in water in the usual way to facilitate sharp breaks, but the apparatus has been very successfully run, at full output, dry, or a little heavy oil on the break suffices. Also, the flux of current in S P, may be made by a magnet to break its own circuit under water when the current has risen to a predetermined amount. In other words, it may be provided with the usual automatic break, damped or adjusted not to get into tremulous vibration. It will be seen from the above description that a new way of energizing an induction coil, or other transforming apparatus, has been embodied and that it consists in the rapid substitution of secondary and primary functions in the coil, S P.

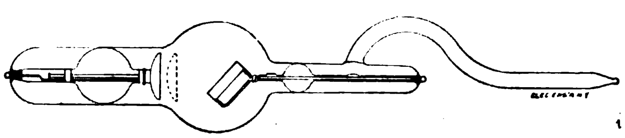
AN IMPROVED ADJUSTABLE X-RAY TUBE.

BY A. A. C. SWINTON.

FURTHER experiment has enabled the writer to design an improved form of adjustable X-ray focus tube which has considerable advantages over the adjustable tubes he has previously described.

The new tube is more easily and cheaply constructed than the multiple cathode tube previously illustrated,[1] while it is also more quickly and readily adjusted. Further, it has a much greater range of adjustment than the movable anti-cathode form of tube, and has the advantage that in adjusting it the position of the anti-cathode, and, therefore, the point of origin of the X-rays is not interfered with.

As will be seen from the illustration, the essential feature of the new tube consists in mounting the cathode upon a steel rod sliding in two aluminum guides, supported in a glass tube,



SWINTON'S IMPROVED X-RAY TUBE.

and connected by an aluminum wire to the cathode terminal. The arrangement is such that by using the tube in a horizontal position, and by simply tapping it at one end or the other, the cathode can be moved to a small extent in and out of tubular neck blown on one end of glass bulb. In this way the position of the cathode can be altered without moving either the tube or the point of origin of the X-rays on the anti-cathode. The exact position of the cathode relative to the glass walls of the tubular neck and bulb, is found to have an enormous effect upon the penetrative value of the X-rays produced. With a suitable and constant degree of exhaustion, if the cathode is placed as shown in full lines in the illustration, X-rays of very high penetrative value are produced, while the small movement of the cathode of about 0.3 inch toward the interior of the bulb required to place it in the position indicated by the dotted lines will suffice to reduce the penetrative value of the rays almost to zero.

Between these two extremes every grade of penetrative value is readily obtained by simply altering the position of the cathode between its limits of travel.

The effect is evidently due to changes in the electrical resistance of the tube, which, as measured by the alternative spark in air, is much highest when the cathode is in the position shown in full lines, i. e., that which gives rays of the greatest penetration, and appears to be closely connected with the distance between the edge of the cathode and the glass which is least in the position just mentioned. This factor is evidently so important that it much more than neutralizes the effect of the alteration to the distance between cathode and anti-cathode, which, as the writer has previously shown, has the result of increasing the penetrative value of the rays, and also the resistance of the tube the nearer these two electrodes are together.

In the tube illustrated the anti-cathode is made of a thick disc of aluminum faced with platinum, in the manner previously described by the writer. This arrangement is found to be very advantageous for tubes destined to be worked with considerable electrical power, say, the full force of a 10-inch Ruhmkorff coil.

Where smaller induction coils are employed, the ordinary form of anti-cathode may be used, but in this case, also, the aluminum-backed arrangement will be found advantageous in that its employment greatly conduces to the permanent maintenance of a constant degree of vacuum.

ELECTRIC TRANSPORTATION

ELECTRIC TRACTION, WITH ILLUSTRATIONS FROM THE PRACTICE OF THE METROPOLITAN ELEVATED OF CHICAGO.[1]

BY M. H. GERRY, JR.

WITH a given number of stops per mile, the amount of power required, will increase very rapidly with the speed beyond a certain point, and the cost per car mile will not furnish a reliable basis of comparison for the motive power of different roads unless the conditions are the same. A slight difference in the average speed, or in distance between stations may cause a considerable change in the amount of power required.

Certain operating conditions have a special bearing on the efficiency of this form of motive power; the most important being the frequency of the train service. If traffic is such that a large number of trains must be operated on a division, the electric power will have an advantage in point of economy, over steam locomotives; and if the trains are few, the reverse will be the case. This condition holds good independently of the weight of the trains or of the speed attained. The length of the line is in itself no bar to the successful operation of an electric railway system, as, by using alternating current apparatus, the power stations may be located favorably, and at long distances apart.

The Metropolitan Elevated Railroad, Chicago.—This system, now in its second year of operation, is the largest road in existence employing exclusively electric power for a heavy passenger service. The structure has four tracks, from Market street west to Marshfield avenue, at which point three double track lines diverge. The northerly branch divides again near Robey street into two double track branches. From Market street to each of the terminals, the distance is about six miles.

Current is conveyed to the trains by the third-rail system; the "trolley rail" being placed 20⅛ inches outside and 6¼ inches above the running rail. It is of the common "T" section, bonded with leaf copper bonds, and divided into sections to provide for expansion. The insulation for the third rail, on all but a small section of the road, consists of hardwood blocks, mounted on small iron chairs fastened to the ties. On a recent extension an improved form of insulation made of stoneware has been tried with success. The electric leakage is small at all times.

The rolling stock consists of motor cars, passenger cars and a few coal and flat cars. The motor cars measure 47 feet in length and weigh about 62,000 pounds when loaded to their maximum capacity. They are mounted on rigid bolster locomotive type trucks, having 33-inch steel-tired wheels. The truck centers are 33 feet 6 inches apart and the truck wheel base 5 feet 6 inches. One truck of each motor car is equipped with two motors, each nominally rated at 2,000 pounds drawbar pull.

The air-brakes are of the direct or "straight" air type with an additional re-enforce cylinder. The air is compressed to 60 pounds by a vertical pump, driven by a motor of about 3 horse-power.

The passenger cars are 47 feet in length and of the standard pattern, in use on all elevated roads. They are mounted on swinging bolster trucks, having 30-inch wheels and when loaded to maximum capacity weigh about 46,000 pounds.

The Power Absorbed by Trains.—In an electric railway system, the mechanical energy supplied at the engine shaft may be divided for purposes of discussion into two general classes. First, that finally absorbed or utilized in propelling the train, and secondly, the energy lost in transformation and transmission, including losses in generators, line rheostats and motors.

[1] Abstract of paper read before the Amer. Inst. Elec. Engrs.

The first division or class, that is, the energy to propel a railway train, may be divided again into three parts: First, that required to overcome inertia and accelerate the train to its maximum speed after each stop. Secondly, the energy required on account of ascending grades. Thirdly, that required to overcome train resistance; including friction, air resistance, etc. If the stations are far apart, the energy required to accelerate the train may be neglected without serious error, but for a service where trains make frequent stops, and the maximum speed is high, compared with the mean speed, it becomes of importance, and may easily be the greatest of all losses.

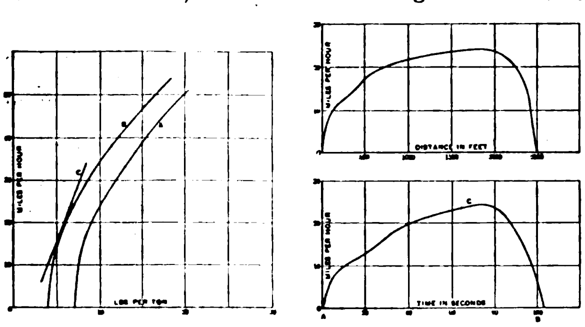
The work done in ascending grades is the product of the

No. of trip	1	2	3	4	5	6	7	8
No. of cars in train	4	4	4	3	3	2	2	4
Total time of trip	28'26"	29'03"	28'30"	28'37"	27'26"	25'30"	23'48"	32'44"
Total time of stops	2–19	2–05	2–42	1–47	1–16	0–54	1–22	1–41
Time running	26–07	26–58	25–58	26–90	26–10	24–36	22–26	31–03
Average speed (including stops)	13.3	13.0	13.2	13.88	14.4	14.9	15.9	11.53
Average speed (not including stops)	14.4	14.0	14.5	14.7	15.1	15.3	16.8	12.2
Average current (including stops)	138.3	142.6	138.6	130.2	129.5	90.1	106.6	101.1
Average current (not including stops)	148.7	153.2	151.8	137.4	135.6	92.5	112.4	106.4
Average volts (at the train)	504	498	503	512	516	521	529	509
Efficiency from generators to car axles	51	50.5	52	50	51	51.5	50	47.5
Kilowatt hours per car mile (at the train)	1.32	1.36	1.32	1.69	1.62	1.58	1.76	2.11
Kilowatt hours per car mile (at the station)	1.44	1.52	1.44	1.81	1.68	1.67	1.69	2.21

train weight and the vertical distance the train is lifted. The horizontal effort required to take a train up a grade is equal to the product of the train weight by the per cent. of grade.

Train resistance, as used in this paper, includes all retarding forces other than those due to inertia and grades. Formulas for determining this quantity are empirical and are based upon experimental results, where the conditions have varied widely. D. K. Clark, in "Railway Machinery," recommends a formula which, reduced to tons, of 2,000 pounds, becomes $R = 7.1 + \frac{v^2}{192}$. Another formula in use is $R = 4 + \frac{v^2}{200}$, where R = resistance in pounds per ton of train weight, v = speed in miles per hour. These two formulas have been plotted in Fig. 1, and are marked, respectively, A and B. From measurements taken on the Metropolitan Elevated, the curve, C, has been determined and is used in the following discussions:

In Figs. 2 and 3, are shown actual speed curves on a time and a distance base, for a train running between stations,



FIGS. 1, 2 AND 3.

2,500 feet apart. For the purposes of discussion, consider the train weight as 100 tons. The average speed taken from the curves in the cases cited is 16.5 miles per hour, not including stops. Allowing 12 seconds for a stop, it is 15 miles per hour.

The average rate of using energy or the power, allowing time for stops, is as follows:

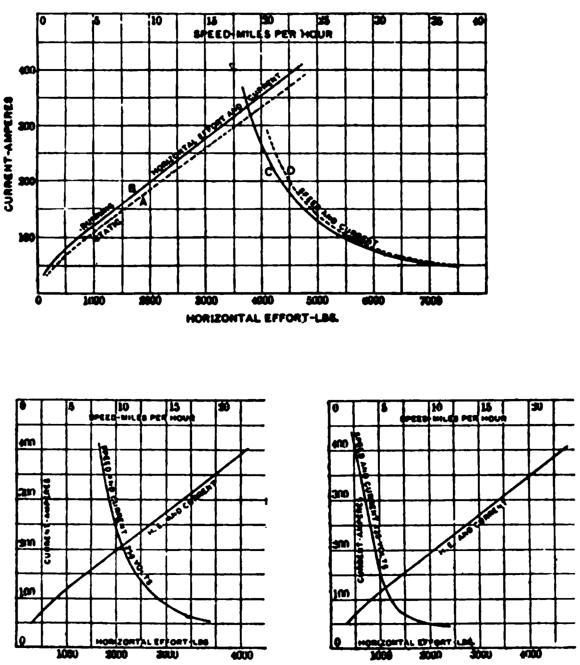
On a 5 per cent. ascending grade ....106.5 h. p.
On a level .... 76.5 h. p.
On a 5 per cent. descending grade .... 46.5 h. p.

The power may also be divided as follows:

For accelerating the train .... 60 h. p.
For ascending grade .... 30 h. p.
For train resistance .... 16.5 h. p.

These figures do not, of course, include losses in applying the power, and only represent the energy which must be applied at the rails to produce the results in the special cases named above. The conditions vary widely at times on the same road, but the above examples may serve to show how great is the percentage of power required to accelerate the trains when the stops are frequent. Motors efficient at high speed are sometimes wasteful of energy because of insufficient torque, at starting and at low speeds, to produce a good form of acceleration curve.

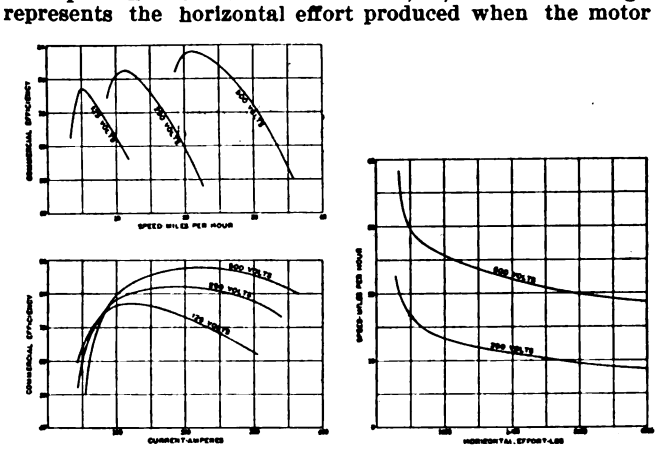
The train weight may be considered as made up of two parts, the live, or paying load, and the dead load, which includes the weight of rolling stock, motors, etc. As the amount of power required by the train varies almost directly as the weight, it is desirable to have the non-paying or dead load as small as possible. Thus, for a service combining high speed and many stops, there are advantages in a form of motor which may be so placed as to utilize a part of the car weight and live load, for purposes of traction. The cars should weigh as little as possible so as to reduce the total dead weight of the train, for it is well known that the ton-miles of paying



FIGS. 4, 5 AND 6.

load form only a small percentage of the total ton-miles moved. On elevated roads it is probably below 6 per cent. on the average and on some roads, below 1 per cent.

The Motors and Controlling Apparatus.—At A, in Fig. 4, the relation between current flowing and the static horizontal effort produced, is shown for the standard motors in use on Metropolitan Elevated Road. Curve, B, in the same figure, represents the horizontal effort produced when the motor is



FIGS. 7, 8 AND 9.

running with 500 volts at the terminals and at the speeds shown by C. The horizontal distance between A and B, represents the loss in horizontal effort due to friction and core losses. Curve, D, in the same figure, gives the speeds which the motor would attain under the conditions named if there

were no internal resistance, and the horizontal distance between the latter curve and C, represents the loss in speed due to such resistance. Thus, the losses in a series motor may be divided into two classes, those that lessen the torque and those that reduce the speed. In Figs. 5 and 6, the relations between current, speed and horizontal effort are plotted for the same motor at 250 and 125 volts.

Curves of efficiency, in relation to the current, are plotted in Fig. 7, for the same voltages. In Fig. 8, the efficiency is plotted to the speed, and it will be seen that the curves fall off rapidly above or below a certain narrow range of speed over which the efficiency is high, at any one voltage.

The relations of speed to horizontal effort are given in Fig. 9. The maximum working range of the motor is from 350 to 4,000 pounds horizontal effort, and the total speed variation on this range at 500 volts will be about 14 miles, and at 250 volts, about 10 miles. With the air at 60 degs. F., and under average working conditions, a Metropolitan motor will radiate heat at the rate of about 650 British heat units per minute. This is equal to 15 horse-power, corresponding about to 60 horse-power of loading. But these motors will readily withstand for a considerable period of time a loading of three times this amount.

The controllers in use on the Metropolitan are two combination series-parallel and have three steps on the rheostat for each voltage. The losses in this apparatus vary from 10 to 20 per cent., depending upon the skill with which it is handled. With care this can be kept down to 10 per cent., making no allowance for the reduced efficiency of the motors at the lower voltages.

The selection of the proper motors and controlling apparatus for a given service deserves more attention than it has generally received. The horse-power and maximum speed have too often been the determining quantities. A rating based on horse-power is now understood to be of little value, and the maximum speed of which a motor is capable may be of still less account as representing its performance with a train. Quite generally, motors have been speeded too high, the result being insufficient starting torque, a poor commercial efficiency and less average speed than a better selected motor would have developed.

The commercial efficiency of railway generators varies from 90 to 95 per cent. Under favorable conditions, the average or "all day" loss for large direct connected machinery (units of over 600 k. w.) is about 7 per cent. Direct connected alternating current generators give about the same efficiency as direct current generators. Commercially, the best results are obtained with a few units of large size. It is unnecessary and poor practice to install many small units for railway work.

A railway load line differs from that of a lighting station in having two nearly equal "peaks," or points of maxima, one in the morning and one in the evening. These variations are best taken care of by cutting in and out units, while the momentary changes can usually be cared for by a slight overloading of the machinery. Engines and generators for railway purposes have a good efficiency over quite a wide range and generally stand overloads very well.

The load curves of the Metropolitan have proven to be a very sensitive index of the traffic. A delay on the competing cable lines or increase of travel from any cause is at once noticeable in the power house. The greater station loading is due not so much to the increased weight in passengers carried, as to the longer stops necessary to discharge and to take on passengers; thus requiring a higher speed to keep the trains on time.

The Efficiency of Transmission.—The energy dissipated between the engine and the car axles may be divided into three parts, that lost in the electrical generators, the losses in the transmission lines (including transformers, rotaries, etc.) and the losses in the car-controlling apparatus and motors.

With machines of 600 to 800-k. w. capacity, the all day efficiency ought to be about 92 per cent. A sub-station provided with rotaries and static transformers working under a good average loading, should have an efficiency of about 89 per cent.; a loss of 8 per cent. in the rotaries and 3 per cent. in the transformers. The sub-station apparatus is at its highest efficiency at the time of greatest loading, when the feeder lines are at the lowest efficiency and thus have a favorable effect on the load line.

The losses on railway feeders vary from 10 to 25 per cent. Often there is sufficient copper if rightly distributed and tied together to reduce this at least one-half. Such a change would also improve the load factor and increase the efficiency of the station.

From a large number of tests made on the trains of the Metropolitan Elevated Road, the following have been selected as illustrating this part of the subject:

Trip No. 1 was made from Franklin street over the Logan Square line with a four-car train, heavily loaded, making an average running time of 13.27 miles per hour. The maximum grade on this line, going west, is 0.75 per cent. ascending for about 2,350 feet, and descending for about 1,950 feet. Other grades do not exceed 0.03 per cent. and only extend short distances.

Trip No. 2 was made with a four-car train, under similar conditions to trip No. 1. In all of the current curves, it is easy to distinguish by inspection when the motors are in series and when in multiple. The stops on the controller are also distinguishable by the greater peaks on the curves.

Trip No. 3 was made under similar conditions to trips 1 and 2, and the data and results are given in the table. Trips Nos. 4 and 5 were made with heavily loaded three-car trains and the results are set forth in the table. Both the speed and commercial efficiency of apparatus are higher than in the case of the four-car trains. Trips Nos. 6 and 7 are with two-car trains and show a higher speed than attained in the case of the three and four-car trains. The greater amount of power consumed in trip 7 is due, mainly, to the increased speed over trip 6.

Trip No. 8 was made with four loaded cars and the motors operating only in series. Both the speed and current are less than for similar trips with the motors operating in series and multiple. The percentage of power saved is greater than that of the reduction in speed, but this is due, not to a better efficiency of the apparatus at lower speeds, but to the fact that the amount of power required to propel a train making many stops, decreases more rapidly than the average speed.

The amount of power lost in the machinery and line, as indicated by the commercial efficiency of the apparatus given in the table, might seem at first thought to be large, but considering the transformation and the distance of transmission, it is certainly not excessive.

Electrical energy can be produced in the vicinity of Chicago, with cheap coal, under the conditions of a railroad load, at less than ½ cent per k. w. hour, and in the form of mechanical energy at the car axles, costing about 1 cent per k. w. hour, it is several per cent. cheaper than it can be generated by steam locomotives. Add to this the actual saving in energy from a more rapid acceleration and from reduced train weight and the total direct advantage for the electrical system is obtained as far as economy in power is concerned.

While any reduction in the cost of power (not only for fuel, but repairs, labor, water, oil and waste, etc.) is of great importance to railroads, the many other advantages of electricity, representing betterments of the service and greater earning capacity are the chief qualities which will determine its adoption in any case in place of steam locomotives. As a motive power electricity is simple, efficient and wonderfully flexible, and it is hardly wise to predict its limitations.

TROLLEY MAIL SERVICE IN MAINE.

The Rockland, Thomaston and Camden Street Railway is the first in Maine to have the United States Railway Mail Service adopted on its road. A separate apartment has been fitted up in a car expressly for the mail service; mails are collected and distributed along the line of the road. The car is 28 feet long over all and is equipped with a Taylor single truck, which has a 6-foot 6-inch wheel base, 33-inch wheels and two G. E. 1,000 motors. The truck is one of the finest riding trucks in the State. The car is capable of running at a very high rate of speed.

The Rockland, Thomaston and Camden Street Railway has just completed a three-quarter mile extension on the Highlands branch. This line runs to the corner of Lime Rock street on the old county road as far as the lime rock quarries. This extension is thoroughly ballasted throughout with lime rock chips and gravel. Mr. T. Hawken is superintendent.

A PULPIT PHRARISEE.

An Indianapolis clergyman made a bitter attack in a so-called sermon a few Sundays ago on ex-President Harrison for appearing as counsel for a street railway corporation in its legal fight against a reduction of fares. "Can any one imagine," asked the reverend gentleman, "the president of a street railroad whose actual value is $2,000,000, but whose watered stock and bonds have a value of $9,000,000, approaching George Washington and offering him $20,000 to justify the greed of the corporation and defend its iniquitous actions from the common people?" And this demagogical gush was applauded.

BROOKLYN HEIGHTS RAILROAD COMPANY has bought sixty new closed cars, twenty each from the St. Louis Car Company, the Laclede Company and the Brill Company.

MISCELLANEOUS

THE EFFECT OF HEAT ON INSULATING MATERIALS.[1]

BY PUTNAM A. BATES and WALTER C. BARNES.

A paper on this subject was presented before the American Institute of Electrical Engineers on May 20, 1896, by Messrs. Sever, Monell and Perry. In the discussion which followed, the results were questioned by several members, and Mr. C. F. Scott cited some investigations of Mr. Skinner, who obtained curves which differed very considerably from those shown in the paper. This left the subject in such an unsatisfactory condition that it was decided to make further tests with the object of reconciling the differences or determining what the real facts are.

In our investigations, more attention has been paid to the actions which take place when one kind of material is subjected to tests while the conditions are varied, rather than a great number of tests on different materials, under the same conditions.

All the tests were conducted on one kind of material, it being safe to conclude from results previously obtained, that the action on it would be quite similar to that produced on other samples. Therefore, the ordinary "red fiber" insulating material having the general appearance of thick red paper has been selected. Its thickness is about .009 inch. The potential used was 500 volts.

The questions that we have attempted to answer by this investigation are four in number, viz.:

1. Does the presence of brass or other metals from which zinc may become volatilized, in the apparatus in which the test is conducted, affect the insulating material or its behavior?

2. Why should one experimenter obtain an insulation resistance curve for fiber, whose minimum point is at about the same temperature as the maximum point of an insulation curve obtained from similar material by another experimenter?

3. What effect on fiber insulating material is produced when it is subjected to conditions similar to those likely to occur in dynamo-electric machinery?

4. What is the action, or actions, that take place when fiber insulating material is repeatedly heated from 20 degs. C. to 200 degs. C.?

Question No. 1 has been approached in the following manner: The resistance of the insulating material at the temperature of the air, or 20 degs. C., being determined, the temperature is gradually raised until 200 degs. is reached, when the test is discontinued. The time taken for this rise was exactly 2½ hours. Resistance measurements were made at frequent intervals, and from these a curve was plotted. The area of insulation tested being 5.5 square inches thickness equals .0095 inch. The position and shape of the curve agrees very closely with the results obtained by Messrs. Monell and Perry, who in their experiment used a brass cylinder, but a confirmatory test with a brass cylinder was also made in our apparatus.

In taking up question No. 2, it is intended to prove, by comparative tests, that the position of the maxima and minima points of the resistance curves, depend upon the opportunity of escape given to the moisture originally contained in the specimen.

It is clear from these two experiments that the position of the curve may be shifted at pleasure by simply varying the opportunity for the escape of the moisture originally contained in the insulating material.

Question No. 3. A new specimen of plain red fiber .009 inch thick was wound with four layers of No. 26 B. & S. bare copper wire, the area covered being 4 square inches, and then subjected to the variations in temperature and exposure to moisture which are most likely to take place in dynamo electric machinery.

Examination of the curves obtained shows that the specimen after exposure to moisture returns to its original condition.

The following conclusions are arrived at by the authors:

(a) The presence of brass in the apparatus does not affect the shape and position of the curve.

(b) The difference in the curves depends solely upon the amount of moisture contained in the material and its opportunity of escape.

(c) Every time the specimen cools the resistance increases to a value much above any resistance that it possessed before, provided it is kept from absorbing moisture.

It is impossible to determine the limit of this action with the present apparatus. But all the curves clearly show this stepping-up effect, which is practically the same as the well known result obtained by baking insulating materials.

[1] Read before the Amer. Inst. Elec. Engrs. Abstract.

TELEPHONY AND TELEGRAPHY

THE ADER CABLE RECORDER.

At the meeting of the Paris Académie des Sciences, last month, M. Ader, of telephone fame, described a new form of submarine telegraph instrument of exceeding beauty, and destined maybe to prove of great practical use. The Ader recorder consists simply of a very fine wire (0.02 mm. in diameter) stretched between the poles of a powerful permanent magnet, in an exceedingly narrow air space. When currents are sent through the stretched wire it tends to move forward or backward in the magnetic field, and these oscillations are recorded in the following manner: The light of a lamp is directed, through a hole in one of the pole-pieces, upon the wire, the size of which is here enhanced by a small cylinder of pith; on the far side of the oscillating wire there is a narrow slit, across which a strip of gelatino bromide of silver paper runs, and on which the movements of the wire are consequently permanently recorded, the paper, after it passes the slit, running straight through a fixing bath. The Adder recorder has been tried on the Brest-St. Pierre cable (2,271 knots), and on the Marseilles-Algiers cables (499 knots). On the Atlantic cable 600 signals per minute were attained as against 400 with the siphon recorder. On the Mediterranean cables signals sent at the rate of 1,600 a minute were easily read.

INDEPENDENT TELEPHONY IN TENNESSEE.

A special dispatch from Knoxville, Tenn., of July 8, says: The Association of Independent Telephone Exchanges of Tennessee was formally organized here to-day. It is intended to include every independent exchange in the State. The organization is the outgrowth of the recent convention of telephone men in Detroit. Its purpose is to fight the Bell system.

THE EFFECT OF SEA WATER ON INDUCTION TELEGRAPHY.

At the last meeting of the Physical Society a mathematical paper was read by Mr. C. S. Whitehead on "The Effect of Sea Water on Induction Telegraphy." If a secondary circuit containing a telephone is rightly placed with respect to the field of a primary circuit traversed by an alternating current, signals may be transmitted over considerable distances. The author investigates the effect of filling the intervening space with sea water; and, generally, the effect of a spherical conducting shell on the induction, at a point in a dielectric, due to an alternating current in a circular circuit, when the axis of the conductor passes through the center of the shell. In the mathematical treatment two cases are considered: 1. To find the normal magnetic induction at any point in the dielectric outside the shell, when a circular circuit carrying an alternating current is placed in the dielectric inside a spherical conducting shell. 2. To find the normal magnetic induction at any point on the remote side of an infinite conducting plate, due to a circular circuit parallel to the plate.

A WESTERN UNION BOY.

The Western Union Telegraph Company's "messenger boy" at Branford, Conn., is Frederick Miller, aged 87, who has a local reputation for his long walks. A message came addressed to a man in North Branford the other day, five miles from the Branford office. Miller started out, and when he got to North Branford he found that the man lived in Northford. On he went, five miles more, found his man, delivered the message and started back, covering a distance of twenty miles.

[*Entered as second-class matter at the New York Post Office, April 9, 1888.*]

VOL. XXIV. NEW YORK, JULY 29, 1897. No. 482.

SUBMARINE CABLES AND THEIR REPAIR.

THE well known cable steamer "Minia," Captain Trott, belonging to the Anglo-American Telegraph Company, arrived at the port of St. Johns, N. F., on the 12th of June, after accomplishing a very important repair on one of the Western Union Company's cables in over 2,500 fathoms of water in longitude 39 degs. west. She sailed from that port on the night of May 23, so that this marvelous feat, including the voyage to and from the position, was completed in less than three weeks, although the weather during the time was reported by all the incoming steamers to be worse than any known at that season for many years. The "Minia" also on her arrival reported much bad weather—she had only three fairly good working days; but, notwithstanding the difficulties encountered on account of the weather, she was only eleven days from recovering the western end until the repair was completed. It is also said that had it not been for a fault in the insulation near the English shore, which had been reported to have been cut out a short time previous by the steamer "Chiltern," and which vitiated the tests taken on board, the repair would have been completed in three days. In the month of April last Captain Trott was visiting this city, and to a few friends, who were calling on him, he said: "I intend on this job—if I get half a chance—to break all records, and to eclipse anything that has ever been done, or likely to be done for some time to come in deep water cable repairing." We are glad to congratulate him on thus breaking his own record.

While on the question of submarine cables, we are reminded of the fact that within a few years there have been some eight breaks in the newest and most modern type of cables, four of which have been very near the longitude of 40 degs. west. By reference to charts, and also from what little we gather by inquiry about the repairs, we learn that the depth of water is almost uniformly about 2,500 fathoms, and that the nature of the bottom is favorable for the preservation of cables. This being so the question naturally arises, what is the cause of so many disasters to the cables, involving as it does such enormous sums of money in the hire of special ships, and in the expenditure of new cable in effecting the repairs? We well remember the failures of two of the largest sized ships in the years 1893-94, involving as it did in both cases another expedition to go out and begin the work de novo in the following years; with the disadvantage of having long lengths of the cables destroyed in the previous years. In the above cases, the hire of ships alone must have been almost a fabulous sum, as the time amounted to nearly six months in each case. The amount of cable used on such repairs usually exceeds eighty miles and often more than 100. Calculating cable at $1,100 per mile and ships at $1,400 per day, our readers may form some estimate of what it costs to keep telegraph submarine ocean cables in working order, to saying nothing about their renewal.

We would be glad if the veteran cable repairer, to whom we have referred above, Captain Trott, of whom it has been said "that he knows the bottom of the Atlantic as a cabman knows the streets of a city" would give us some information on the cause of such destruction to cable property. It would be of incalculable benefit to those who invest their money in such enterprises.

COLLEGES IN POVERTY.

IT is said that if Governor Hastings, of Pennsylvania, had not signed the bill appropriating $150,000 for the support of Lehigh University the institution would have had to close its doors, owing to the failure of the Lehigh Valley Railroad to pay dividends on the stock left as an endowment by Asa Packer. The news of financial distress has been received with surprise and pain, as it was supposed that Lehigh was rich and strong, both in present funds and in its prospective receipt of other endowment. But it is now understood that the income of last year was chiefly derived from tuition fees, although it was the design of the founder that the excellent special training at Lehigh should be free of charge. Last year 415 students were in attendance. Outside the gifts at the foundation, to build the university, Mr. Packer left $1,500,000 for endowment and $500,000 for a library, little dreaming that a time could come when the profitable Lehigh Valley road would fail to yield a handsome return.

The money available for technical education is still so small, one dislikes greatly to see it reduced or in peril in this manner; but, falling back on the State does not commend itself to our judgment, nor is the incident unique. We wish it was. The wonder is that with 400 colleges in this country granting degrees and diplomas, the number of those that come to grief is not larger. Perhaps if we had 100 colleges, things might be better, but even the seats of learning of the best type or largest resources totter now and then. The parlous condition of Johns Hopkins is familiar history, and everybody knows that Palo Alto escaped great disaster by the skin of its teeth. Nor are evil days limited to modern institutions, for Oxford and Cambridge have both been affected seriously by the decline in the value of English farm lands. Nor is the phenomenon one that is new. The University of Geneva was once so hard up that it was in danger of closing its doors, and the Company of Pastors offered their own salaries to find bread for the professors. At the beginning of the sixteenth century, the University of Paris was in deep decay, forty of its colleges were empty of students, and many of the buildings were overgrown

with verdure. But to-day both are strong and prosperous. Perhaps it is as impossible to secure a university against the downs of fortune, in perpetuity, as any other institution, for stocks, bonds, lands, city estates and all other forms of earning funds, are liable to vicissitude; but there are certainly remedies for the state in which many of our American colleges find themselves, and one of these would be that favorite modern process of consolidation.

A PIOUS PILGRIMAGE.

WE give a report of the meeting this week of the American Institute of Electrical Engineers at Greenacre-on-the-Piscataqua, Me., held at that spot in order to assist in celebrating the jubilee of the operation by Prof. Moses G. Farmer, of an electric passenger road at Dover, N. H., near by, the work in electricity of that brilliant but diffident and reserved inventor, dating from that period. It was hardly expected that in a remote corner of Maine a national society could get many of the members together, but the attendance was good and representative and some excellent work was done. Not the least of many pleasing recollections of the week will be the charming hospitality of Miss Sarah J. Farmer and her associates in the Greenacre Conference; while it may be hoped that a permanent record will be found in a memorial to Prof. Farmer himself and the publication of some of the valuable data now lying lost in his 15,000 pages of experimental records, preserved at his quiet Greenacre home.

THE NEW TARIFF.

THE new tariff schedule, which went into effect last week, will, in general, affect the electrical industries very little, such increases in the rates as have taken place being upon products of minor import. The notable exception to this, however, is the duty on arc light carbons, which has been increased from 20 per cent. ad valorem to 90 cents per 100, or $9 per 1,000. This increase is one of the largest, if not the largest. on the entire list, representing a duty of anywhere from 50 to 150 per cent., depending on the size of carbon. It is more than probable that this high rate will effectually shut out carbons of foreign make for the present. Yet there are some who believe that, in spite of its increased cost, the quality of the imported article will make its use desirable in enclosed arc lamps, for instance. American carbon manufacturers now have a great opportunity of showing what they can produce, and we hope that they may succeed in their attempts to furnish a carbon equally as good as, or better than, the imported.

PROF. ELIHU THOMSON AND X-RAYS.

ONE of the most noteworthy signs of the day is the manner in which the daily press takes up the new things in science and invention and makes the knowledge of them common property. Very often this is done in a sensational way, but, even when at its worst, the mere fact that crime is not the only side of life to think about is impressed in this not altogether useless way upon a public that would hardly otherwise know anything at all of intellectual and industrial advance. There are some journals that treat these subjects in a dignified yet helpful and interesting style, and chief among them is certainly the New York "Sun." It is for this reason that we may be the more free to correct statements made by it which, if made by some of its inestimable contemporaries, would be passed by with silent contempt. Thus, an article in the "Sun" for Sunday, July 18, on the danger of the X-rays may be mentioned as one of those in which the writer, though probably good in purpose, falls lamentably short of the "Sun's" average high standard of accuracy. Reference in it is made to the work of various men, and that of one of them, Prof. Elihu Thomson, is, to say the least, ludicrously misrepresented. It will be remembered that Prof. Thomson recorded in the electrical papers the results of an experiment made deliberately with his little finger to determine certain facts as to X-ray inquiry for himself. The "Sun" article says that he did this in ignorance and "acknowledged his error in a lecture" and exhibited his finger "as proof that he had been wrong." It is a hard fate to martyrize even a little finger in the cause of science, and then to have it thus paraded as having been done in the cause of ignorance. Prof. Thomson's purpose was obviously to show that the X-rays were to blame for the trouble, but, at the same time, he wished to allay apprehension of injury when proper conditions were observed, realizing that the beneficent use of the rays in surgery might be hindered if people should acquire an exaggerated notion of the risk of injury. When Prof. Thomson gave his valuable data, there were all kinds of theories in the air, as to electro-static effects, thermal effects, ozonic effects, etc., and his experiments went to show, and it would seem, resulted in proving that the burns were due to the rays themselves. And yet the "Sun" man goes out of his way to talk of Prof. Thomson's "errors" and avowal of ignorance. As we recorded the original tests, we object very decidedly to this gross perversion of fact and history, which might well make Prof. Thomson glad that he risked only a little finger.

THE TROLLEY DECISIONS.

THE decision of the U. S. Circuit Court of Appeals, reversing the order of Judge Coxe, who granted a preliminary injunction against the Hoosick Railway Company, will come as a surprise, albeit a by no means disagreeable one, to all interested in electric railway work. For the time being it leaves the use of the trolley free in the judicial district covered by the Second Circuit. In one sense it is a heavy blow to the validity of the Van Depoele trolley patent, as foreshadowing to some extent, at least, the final opinion of the court. But, on the other hand, it must not be forgotten that the case was not before the Appellate Court on final hearing, the question being simply whether Judge Coxe was justified in granting the injunction. It will be recalled that in the U. S. Circuit Court of Appeals for the Sixth Circuit, where the same question was at issue, the court below was sustained in its decision granting an injunction against alleged infringers. Considering the fact that two Appellate Courts have taken opposite views on the same question, there is probably little doubt that the U. S. Supreme Court will be asked to take up the case for adjudication. Another point to be considered is the fact that of the sixteen claims of the trolley patent, but five were involved in the Hoosick case. There are other claims which the owners of the patent claim to be of importance and which have only recently been passed upon.

These additional claims were involved in a suit brought against the Detroit Citizens' Street Railway Company in the Circuit Court of the United States, Eastern District of Michigan. In that case an order for a preliminary injunction was granted July 15, the defendants being enjoined from infringing the second and fourth claims, as well as those specified in the Hoosick case. The bill of complaint in the Hoosick case, we understand, has been amended and the courts of the New York Circuit will be asked to consider these additional claims with the others, when the case comes up for final hearing. The decision just rendered, of course, in no way affects the Van Depoele patent on the under-running suspended switch for trolley circuits, and the General Electric Company will probably take some comfort in the fact that on July 15 the Detroit Citizens' Street Railway Company was also enjoined from using the suspended switch on its system. So far as the trolley itself is concerned, honors appear to be about even, and it will probably be several years before a final decision in the matter can be reached.

THROUGH an error of the engraver the designation "Hours" was omitted for the abscissa line of the engraving, Fig. 1, page 75 of this issue. Likewise in Fig. 2, on the same page, the ordinates represent "Watts per Candle" and the abscissæ "Hours."

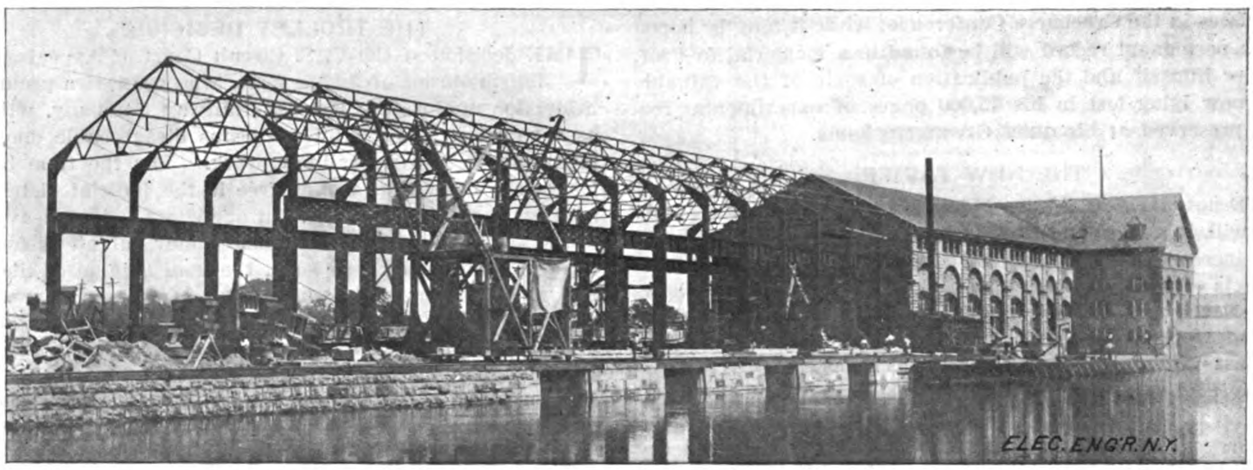
NIAGARA POWER HOUSE EXTENSION.

By ORRIN E. DUNLAP.

THE steel frame of the extension of the Niagara Falls Power Company's power house has been erected, and Contractors R. D. Young & Co. are erecting the masonry. The original section of this great power station is 140 feet long, and the extension is 286 feet, making a total length of 426 feet. This total length will afford room for ten 5,000 horse-power generators of the same style as those in use at present, and five of the seven additional generators have been ordered of the Westinghouse Electric and Manufacturing Company. The additional turbines have also been contracted for, and will be made by the I. P. Morris Company, of Philadelphia.

In the extension the same pleasing style of architecture will be adhered to as that which is so pronounced and beautiful in the first section of the building. E. D. Smith & Co., the firm having the contract for the extension of the wheel pit, have finished the excavation necessary under their contract, and the work of bricking up the lower portion to a height of about 30 feet is about to commence. This brick wall will be about 30 inches thick and about 1,500,000 brick will be used in building it.

Resident Engineer Brackenridge, of Cataract Construction Co., is hurrying the work with all possible speed. Mr. Brackenridge's experience on the original section of the work has proved very valuable during the work of extension, and has been a material factor in the progress made. When completed the imposing nature of the power house will be greatly increased, as is evident from the illustration presented herewith.



THE NIAGARA POWER HOUSE EXTENSION.

THE ALTERNATING CURRENT INDUCTION MOTOR.[1]—I.

BY CHARLES PROTEUS STEINMETZ.

POLYPHASE INDUCTION MOTOR.

Load Curves.—In its general behavior the alternating current induction motor is analogous to the continuous current shunt motor. Like the shunt motor it operates at approximately constant magnetic density. It will run at fairly constant speed, slowing down gradually with increasing load. The main difference, however, is that in the induction motor the current is not passed into the armature by a system of brushes, as in the continuous current motor, but induced in the armature by the alternating field, and in consequence thereof, the primary circuit of the induction motor fulfills the double function of an exciting circuit corresponding to the field circuit of the continuous current shunt motor, and an inducing circuit producing the current in the armature by electromagnetic induction.

The secondary or armature of the motor consists of two or more circuits displaced in phase from each other so as to offer a closed secondary to the primary circuits, irrespective of the relative motion. The primary consists of one or several circuits.

The characteristics of the transformer are independent of the ratio of transformation, other things being equal. That is, doubling the number of turns for instance, and at the same time reducing their cross-section to one-half, leaves the efficiency, regulation, etc., of the transformer unchanged. In the same way in the induction motor it is unessential what the ratio of primary and secondary is, or, in other words, the secondary circuit can be wound for any suitable number of turns, provided the same total copper cross-section is used. In consequence thereof the seconodary circuit is mostly wound with one or two bars per slot, to get maximum amount of copper; that is, minimum resistance of secondary.

In the following under secondary current, e. m. f. impedance, etc., shall always be understood their values reduced to the primary, or corresponding to a ratio of turns 1 to 1, although in practice a ratio 1 to 1 will hardly ever be used, as not fulfilling the condition of uniform magnetic reluctance desirable in the starting of the induction motor.

Let in the polyphase induction motor,

$Y_0 = g + jb$ = primary admittance, or admittance of the primary circuit at open secondary circuit.

$Z_0 = r_0 - jx_0$ = primary impedance.

$Z_1 = r_1 - jx_1$ = secondary impedance induced to the primary by the ratio of turns.[2]

All these quantities refer to one primary circuit and one corresponding secondary circuit.

The "efficiency" or "power efficiency" is the ratio of the true mechanical output of the motor to the output which it would give at the same power input if there were no internal losses in the motor. The "apparent efficiency" or "apparent power efficiency" is the ratio of the mechanical output of the motor to the output which it would give at the same volt-ampere input if there were neither internal losses nor phase displacement in the motor.

The "torque efficiency" is the ratio of the torque of the motor to the torque which it would give at the same power input if there were no internal losses in the motor.

The "apparent torque efficiency" is the ratio of the torque of the motor to the torque which it would give at the same volt-ampere input if there were neither internal losses nor phase displacement in the motor.

From the quantities: Primary aumittance, primary impedance and secondary impedance, the induction motor can be calculated.

As instance, in Figs. 1 and 2 are calculated the load and speed curves of a 60-cycle three-phase eight-polar motor, 110 volts impressed, of the constants: $Y_0 = .045 + .384\,j$; $Z_0 = .045 - .124\,j$; $Z_1 = .041 - .124\,j$ per circuit in delta connection. 510 watts are allowed as friction at synchronism.

The output and torque are three times the values derived directly from calculation since the motor contains three cir-

[1]Read before the Amer. Inst. Elec. Engrs. Abstract.

[2]The self inductive reactance refers to that flux which surrounds one of the electric circuits only without being interlinked with the other circuits.

cuits, an.. the current shown in the diagrams is the current per line, or $\sqrt{3} \times$ the current derived from calculation.

In Fig. 1 are shown in drawn lines the speed, efficiency and current input ot the motor with the h. p. output as abscissæ, in dotted lines the apparent efficiency, and in dash dotted lines the power factor.

In Fig. 2 are shown with the speed or the slips in per cent. of synchronism as abscissæ, the torque as ordinates for the three-phase armature resistances: $r_1 = .041$, or short-circuited armature; $r_1 = .38$; $r_1 = .76$. This motor is the I-8-30-900-110, Form A, of General Electric Company's make, and the results of test of this motor are marked in Figs. 1 and 2 by crosses,

which may be called the characteristic constant of the motor.

The power factor of primary admittance $\beta = \frac{g}{y}$.

The power factor of impedance $\gamma = \frac{r}{z}$.

In the above equations, y equals the absolute admittance; z equals the absolute impedance, and g equals the conductance.

The characteristic constant of the induction motor $\vartheta = 2\,yz$ is the ratio of exciting current to short-circuited current.

The characteristic constant is also approximately the ratio

FIGS. 1, 2, 3 AND 4.

showing the exceedingly close agreement between the calculated values and the results of test.

Equations show that in an induction motor, the efficiency, power factor, apparent efficiency, torque efficiency, apparent torque efficiency at a given slip or speed, and thus starting torque per volt-ampere or watt input are independent of the impressed e. m. f. The current and counter e. m. f.'s are proportional to the impressed e. m. f.'s.

The torque, power and volt-amperes are proportional to the square of the impressed e. m. f. This obviously applies only as long as the iron is below saturation, which, however, is always the case.

Rating the induction motor at a given percentage, say, ⅔ of maximum output or of maximum torque, the characteristic features of the motor are seen to be entirely independent of

of total self-inductance to mutual inductance of the motor circuits.

To exhibit the effect of the variation of constants on the behavior of the induction motor, a number of characteristic motors have been calculated and the load curves of some of them are shown in Figs. 3 to 7, while an abstract of their constants is given in the accompanying table.

No. 1, with load curves shown in Fig. 3, refers to the best motor which can be built at frequencies of 40 to 60 cycles. As seen, the efficiency rises very rapidly at light loads, reaches a maximum of 91 per cent., and then slowly drops to 88 per cent. at full load. The power factor rises somewhat slower, but is already 74 per cent. at quarter load. The apparent efficiency is very high also, above 80 per cent., and rises at light loads quite rapidly. The exciting current is very small.

CONSTANTS OF INDUCTION MOTORS.

$E_0 = 110.$

(The motors marked by × are typical motors.)

No of motor.	No. of diagram.	$Y = g + jb$	$Z = r - jx$	$\vartheta = 2yz = y(z_0 + z_1)$	$\beta = \frac{g}{y}$	$\gamma = \frac{r}{z} = \frac{r_0 + r_1}{z_0 + z_1}$	T_m = max. torque, synchr. kilowatt. the impressed e. m. f. and merely dependent upon the admittance and the impedances.

A change of one of the impedances has comparatively little effect on the motor characteristic, provided that the other impedance is changed so that the total impedance remains the same.

Thus the induction motor is characterized by three constants only: The product of admittance and impedance $\vartheta = 2\,yz$,

The drop of speed, 6 per cent., at full load, could be made less by lessening the armature resistance. In very large motors as close a speed regulation as 1 to 1½ per cent. has been reached. Thus this motor is equally as satisfactory at light loads as at heavy loads.

No. 2 in Fig. 4 shows the typical high resistance motor. It is characterized by poor speed regulation, a drop of 11 per cent. at full load, an efficiency curve reaching very high values

at light load, but falling off with load, while the power factor rises slowly, but reaches very high values at heavy loads. The apparent efficiency is quite fair and the exciting current the same as in the first motor, thus due to the decreased output of this motor a somewhat higher percentage of full load current, when rating the motor at ⅜ maximum torque.

SOCIETY & CLUB NOTES

NORTHWESTERN ELECTRICAL ASSOCIATION.—FIFTH SEMI-ANNUAL CONVENTION, LA CROSSE, WIS., JULY 21-22 1897.

THE fifth semi-annual convention of the Northwestern Electrical Association was held at La Crosse, Wis., at the City Hall, July 21 and 22, 1897.

The meeting was called to order by Vice-President G. L. Cole, of Beloit, Wis., in chair, at 10:50 A. M.

The following were in attendance:

E. H. Abadie, St. Louis, Mo.; R. A. Albrecht, La Crosse, Wis.; Herman Andrae, Milwaukee, Wis.; C. W. Bacon, Madison, Wis.; W. Worth Bean, St. Joe, Mich.; G. C. Bell, La Crosse, Wis.; F. N. Boyer, Chicago, Ill.; Loren W. Burch, Madison, Wis.; G. L. Cole, Beloit, Wis.; Columbia Incandescent Lamp Company, St. Louis, Mo.; F. A. Copeland, La Crosse, Wis.; A. A. Cross, West Superior, Wis.; George Cutter, Chicago, Ill.; E. L. Debell, Sheboygan, Wis.; James R. Dee, Houghton, Mich.; Fred. De Land, Chicago, Ill.; Henry L. Doherty, Madison, Wis.; Casper Faust, Rhinelander, Wis.; T. Ferris, Milwaukee, Wis.; F. H. Ford, Madison, Wis.; G. B. Foster, Chicago, Ill.; A. C. Garrison, Madison, Wis.; H. J. Gille, St. Paul, Minn.; G. H. Greenwood, La Crosse, Wis.; H. C. Hackney, Madison, Wis.; Jos. M. Hill, Chicago, Ill.; L. B. Howorth, Minneapolis, Minn.; I. D. Hurlbut, Prairie du Chien, Wis.; George H. Jones, Fond du Lac, Wis.; C. E. Kammeyer, Chicago; John S. Keller, Prairie du Chien, Wis.; F. Kellogg, Spencer, Ia.; F. J. Killian, La Crosse, Wis.; P. H. Korst, Racine, Wis.; I. B. Kuntesen, La Crosse, Wis.; A. N. Loper, New Haven, Conn.; W. W. Low, Chicago, Ill.; F. P. Luther, Chicago, Ill.; G. G. Luthy, Peoria, Ill.; J. H. McGill, Chicago, Ill.; T. Julian McGill, Chicago, Ill.; J. D. McIntyre, P. S., Syracuse, N. Y.; F. McMaster, Chicago, Ill.; John S. Maurer (Crouse-Tremaine Carbon Company), Fostoria, Ill.; Thomas R. Mercein, Milwaukee, Wis.; C. M. Morgan, Preston, Ill.; George M. Newton, Sparta, Wis.; Pliny Norcross, Janesville, Wis.; C. C. Paige, Oshkosh, Wis.; H. F. Pearce, Negaunee, Mich.; C. H. Pease, Richland Center, Wis.; W. S. Raymond, L. D. Richardson, La Crosse, Wis.; J. H. Schlake, Freeport, Ill.; R. F. Schuchardt, Milwaukee, Wis.; John Schuette, Manitowoc, Wis.; George D. Shepardson, Minneapolis, Minn.; James J. Sheridan, La Crosse, Wis.; W. R. C. Smith, Chicago, Ill.; M. L. Stevenson, Cleveland, O.; George S. Stiles, La Crosse, Wis.; W. P. Sullivan, Chicago, Ill.; R. A. Swain, Chicago, Ill.; G. L. Thayer, Belle Plaine, Ia.; W. H. Upham, Marshfield, Wis.; W. P. Upham, Chicago, Ill.; P. Valier, La Crosse, Wis.; Geo. S. Whyte, Chicago, Ill.; James Wolff, Chicago, Ill.

The vice-president opened the proceedings by a short address, after which the report of the secretary and treasurer was read by Mr. T. R. Mercein, to whom a hearty vote of thanks was accorded.

The Programme Committee then presented its report.

The secretary said that there had been considerable discussion in previous conventions in regard to the action of manufacturing institutions, and read the following letter, under date of June 21, 1897, relative to the proposed municipal plant at Racine, Wis., addressed to the secretary:

"Dear Sir: On my return to-day, find your inquiry of the 14th inst. In connection with this matter, desire to state, we are in no wise interested in Racine, Mr. Roberts or a municipal plant for Racine. We have heretofore sold Mr. J. I. Case considerable apparatus, and it is not likely we would enter the field, establishing an electric plant in opposition to him.

"Some time ago we wrote our representatives regarding municipal ownership, as per the enclosed letter. This, from the fact that some parties connected with the Northwestern Electrical Association stated we were endeavoring to install municipal plants.

"Please understand we feel there is no company in the United States that has lost as much money by municipal ownership as ourselves. We owned two lighting plants at Detroit, when municipal plant was established; one of these plants was thus rendered practically worthless. At Logansport, Ind., we also lost a plant valued at $80,000; this is now closed up with only a watchman in charge.

"Trusting the above explains our position in the matter, we remain, very truly, C. C. KNIGHT,
Vice-President Fort Wayne Electric Corporation."

The letter referred to is a circular letter issued by the Fort Wayne Corporation to its agents and concludes as follows:

"We have always opposed municipal ownership where companies are in existence and never have taken a part in the establishment of municipal plants until the local people are absolutely unable to secure lighting contracts and the city, town or village has advertised for proposals to the end of letting a contract for the establishment of a municipal plant. On receipt of such information we feel we are entitled to bid on said work.

"We would be pleased to have any definite information you may have as to parties circulating the report that we favor municipal ownership."

MR. P. H. KORST, of Racine, explained briefly the origin of the Racine inquiry.

The secretary then read the names of sixteen individuals and corporations who were admitted to membership.

After accepting an invitation to a trolley ride, the convention adjourned till 2 o'clock P. M.

AFTERNOON SESSION.

The association was called to order by the vice-president.

The secretary then presented two applications for membership, which were acted on favorably.

A paper was then read on "Utilization of Exhaust Steam," by Mr. George L. Thayer, of Iowa.

MR. DOHERTY inquired whether Mr. Thayer could give any figures on the installation charge per unit of income, say, $100 of income.

MR. THAYER.—Figuring on the basis of 100 horse-power, it will bring about $2,500 income after you have fully loaded up your mains. Auxiliary apparatus and power house will cost about $5,000. Of course, there comes in the added expense of installing the apparatus in the building, which is about $20 per horse-power. I presume you could turn over your capital about once in three or four years if your conditions are favorable. A heavy condensation loss and main loss might become important factors, however. A 6 or 8-inch main costs pretty near a dollar a foot to lay.

MR. DOHERTY.—I think you would get about the same return as we do on our lighting plant as compared with our installation charge.

MR. THAYER.—It is claimed that under good conditions a plant will last twenty years. There are small underground mains that were installed by the firm for which I worked, that I know are in good condition after fifteen years' use. Pipe laid in tiling would have too much conduction loss. It has been a practice to use nothing except a wooden log or trough, except in New York City, where brick tunnels are employed on account of the heavy service. Two thousand five hundred dollars is the gross income. The profit depends entirely upon how much exhaust steam one has.

MR. DOHERTY.—We have a street railway built at home and I was figuring on storage batteries to carry the peak of the load. Their first cost would be in the neighborhood of one-fifth more than the entire equipment of engines, boilers and dynamos in the plant. Their efficiency would be about 80 per cent. The Chloride Company would not guarantee to maintain them for less than 7 per cent. In connection with the use of exhaust steam I came to the conclusion that in our circumstances we gain more by condensing than by exhaust steam. A great many stations are equipped with high speed engines that are not adapted to run condensing, and the exhaust steam is wasted entirely. But I think a great many of us could make a marked saving by looking up the question of condensation.

MR. THAYER stated that the storage battery scheme suggestion in his paper was simply thrown out as a suggestion with the idea that under certain circumstances it would pay.

PROF. G. D. SHEPARDSON stated that in regard to the effect of outside packing in the eating out of pipes, it might be of interest to the street railway people to know that electrolytic action is not the sole or often the probable cause of this condition. He had no doubt a great deal of trouble attributed to return currents of street railways was really due to chemical action in whatever surrounded the pipe rather than

to electrolytic action pure and simple. He cited such a case as occurring in the Minneapolis City Hall.

A paper was then read by PROF. G. D. SHEPARDSON, of the University of Minnesota, on "220-Volt Lamps."[2]

During the course of the reading of his paper Prof. Shepardson called attention to some curves of tests of 220-volt lamps made by his students. One sheet was made up from the averages of the five lamps of each of four different makes. The initial candle-power varied at the start from 13.6 candle-power, the average of one lot of lamps to 19.8 as the average of another lot. But all these lamps were marked 16 candle-power and were tested at the voltage for which they were marked. The good lamps started at an average of 4.6 watts per candle and, going up to 4.45 in 30 hours, then increased to 4.8 in 90 hours and 4.94 watts per candle in 921 hours. The 10 watts per candle lamp would probably have lasted 6,000 hours if it had been kept going. (Laughter.)

PROF. SHEPARDSON, in reply to a question, stated every one of the municipal plants that he knew of personally had water-works in connection with them—that is, in the same building, and he did not think, therefore, that the figures were worth the ink they are written with. There was nothing allowed for interest or depreciation.

MR. McGILL.—Our company (Siemens & Halske) are pioneers in the use of the 220-volt system, but they have never compared the two systems. They claim that the 220-volt system is more economical than the alternating system under certain circumstances and conditions. It is cleaer, moreover, that for a distance of not more than 1,000 feet the 110-volt system is preferable. But there is no comparison to be made between the 110-volt system and the 220-volt system for distances of 3,000 or 4,000 feet. Capt. Richardson, in Fort Wayne, Ind., went into a detailed investigation to determine whether the alternating system, the 220-volt or the 110-volt system was best to be used in the new court house in that city, and finally the 220-volt system was decided upon. But I do not think you should compare the 220-volt lamp with the 110-volt lamp, and I myself think the 110-volt system is a more economical one.

After further discussion by Prof. Shepardson and Mr. Doherty the convention adjourned until the next day.

THURSDAY, JULY 22.—MORNING SESSION.

The convention was called to order and then went into executive session. The Committee on Legislation presented its report, which was accepted.

MR. DEE moved that the secretary be instructed to confer with the secretary of the National Electric Light Association as to what action the two associations would take with regard to making a report on municipal ownership to the Bureau of Statistics at Washington. Carried.

Adjourned to 2 P. M.

THURSDAY AFTERNOON SESSION.

The secretary stated that he had received some correspondence in the matter of telephone membership; so far as he understood the scope of the association it was only too glad to welcome any one connected in any way with any electrical industry, which would also cover electric railway plants in the Northwest.

A rising vote of thanks was extended to Mr. F. A. Copeland, of La Crosse, for the beautiful badge presented to each member and for the pleasant entertainment arranged by him.

It was decided that the price of the association's central station pamphlet be hereafter made one dollar.

A paper on "The Constant Potential Arc," by O. M. Rau and F. A. Vaughn, was then read by the secretary.

MR. R. F. SCHUCHARDT then read a paper, entitled "The Meters of To-day."

At the conclusion of the reading of his paper, Mr. Schuchardt showed a design of a meter testing rack, made by Mr. Judd, and gave the results of tests on several makes of meter. The paper was discussed by Mr. Thayer.

THE PRESIDENT then appointed as Committee of Entertainment for the next meeting Messrs. H. L. Doherty, W. L. Church and L. B. Caswell, Jr.; as special Committee for Municipal Subjects, Col. W. W. Bean, J. R. Dee and A. A. Cross.

After various votes of thanks for courtesies extended, the convention adjourned sine die.

CONVENTION NOTES.

ON TUESDAY NIGHT the 10:15 train left the Chicago & Northwestern depot with special sleeper attached, in which the Chicago contingent traveled to La Crosse.

WHEN THE WEDNESDAY afternoon session concluded all the visitors repaired to the Fair Grounds, where some bicycle races took place. Among the contestants in the first event were James Wolff, T. J. McGill, F. McMaster, J. D. McIntyre, J. V. S. Church, G. B. Foster and two local men, Otto Langstadt and Philip Linker. The judges of the meeting being unaware of Linker's racing qaulities, gave him only a short handicap; and all the others started even. Linker came in an easy winner, with Langstadt, the other local man, second. The prize for this race was a handsome acetylene lamp.

In the second heat C. Schuchardt was made to go around the track alone to equalize matters. He finished first in the heat, with Foster second, and received a pair of bicycle hose.

While the contestants were having a rest a Fat Man's Race was gotten up, in which James Wolff, Thomas Ferris and C. H. Pearce, all stalwart representatives of the States of Illinois, Wisconsin and Michigan, competed for the honor of riding first to the winning post. Pearce, the Michigan man, although top weight and weighing 260 pounds, led nearly all through, and won easily, with Wolff second. Next came a slow race, which was won by T. J. McGill, who also won the following heat, with F. McMaster close in his wake. This ended the racing and the visitors returned to town.

AT 7:15 WEDNESDAY EVENING the visitors boarded a trolley and two trailer cars, which were handsomely decorated, and made an enjoyable trip to North La Crosse; on the return journey stoppages were made at the street railway power house, and the Brush and Edison lighting plants, all of which were inspected. The cars then took the visitors to the Germania Hall, where they were most agreeably entertained by the Deutscher Verein. Mayor McCord was introduced by Col. Copeland and made an address of welcome to the visitors present. This was followed by an address by Secretary Mercein, and some of the visitors, including George Cutter, F. L. Perry and others. Fine vocal and instrumental selections were rendered by J. R. Kerr and Langstadt's orchestra.

ON THURSDAY AFTERNOON about a dozen private steam and gasoline launches, led by Col. Copeland's Neche, proceeded up the Mississippi River for about six miles until Eagle Point bluff, on the opposite Minnesota shore, was reached, where the party disembarked; then the visitors feasted their eyes on the beautiful scenery which lay before them on all sides. After viewing the surroundings the party sat down and partook of a very plentiful supper most hospitably provided by Col. Copeland. When supper was over, Mr. Thomas Mercein acted as toast master in his usual inimitable style and called upon several of those present to speak. Among those who responded were Messrs. Woodward and Hogan, of La Crosse; W. W. Low, James Wolff, F. L. Perry, W. W. Bean and George Cutter. About 7:30 the party boarded the launches for the return trip, which was made very rapidly as a four-mile current was running down the river. The squadron were saluted by fireworks and gun firing from several of the summer cottages situated on the west bank of the river. La Crosse was reached about 8 o'clock and before leaving the city cheers were given by the visitors for Col. Copeland and the Entertainment Committee.

THE HANDSOME SOUVENIR presented to the visitors by Col. Copeland at Wednesday's meeting was greatly admired and will be kept as a memento of the pleasant time enjoyed by the visitors to La Crosse.

EXHIBIT NOTES.

J. HOLT GATES & CO., of Chicago, were very ably represented by Mr. George B. Foster, who has recently become associated with that concern. Mr. Foster had a strict eye to business and reminded those present that the Wagner, Walker and Card companies were thoroughly up-to-date concerns.

THE ELECTRICAL PRESS had the following representatives on hand: "Western Electrician," F. L. Perry; "Electrical Review," Carl Kammeyer; "Electrical World," J. V. S. Church; The Electrical Engineer, W. P. Sullivan; "American Electrician," W. R. C. Smith; "Electrical Engineering," Fred. De Land.

THE CHICAGO GENERAL FIXTURE COMPANY had their popular representative, Mr. L. W. Kittman, around, who showed that he was thoroughly well able to combine business with pleasure on the occasion.

MR. GEORGE CUTTER, of Chicago, was also in attendance and, with his usual obliging way, looked after the transportation arrangements for the Chicago contingent, and saw that their personal comforts were attended to.

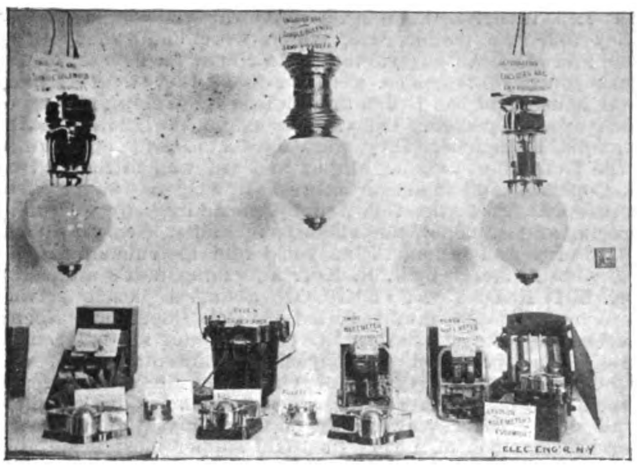
MR. JOSEPH M. HILL, Western manager of the Bryan-Marsh Company, was to the fore and renewed acquaintances with several of his old friends in the Northwest.

THE WASHBURN & MOEN MANUFACTURING COMPANY were well represented by their St. Paul agent, Mr. J. D. Gille, who presented those who attended with a most complete pocket handbook which had a fund of information relating to copper and iron wire, and other very useful matters connected with the trade.

THE PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., showed a very nice line of their porcelain special-

ties, including main and branch blocks, tubes, cleats and rosettes. All who saw their one-way plug cut-out were greatly pleased with it. This block is made in the single, double and triple style. The Peru Company also manufacture the well known Laclede battery. Mr. F. D. Covington, who has been with this concern for several years and represented them at the convention, states that he has not yet met with any of his customers who has had any fault to find with their goods.

THE GENERAL ELECTRIC COMPANY had a very representative exhibit, under the care of Messrs. F. N. Boyer and R. A. Swain, of the Chicago office, and Thomas Ferris, their Wisconsin representative. The exhibit comprised a full line of testing instruments for station switchboard, portable and pocket use. These instruments are of the well known inclined astatic type and are adjusted for any voltage or amperage. The portable wattmeter has given exceptional satisfaction after severe testing. A 600-watt type H transformer was shown,



General Electric Co.'s Exhibit.

having a unique arrangement for connecting the primary and secondary leads. This transformer is now so well known that it is not necessary to make any comments on its efficiency.

The company's meter display was very complete and represented the full line from two-wire 50 and 100-volt, to 220-volt three-wire for direct current systems. The arc meters were in evidence, both for station and store work. A new street car meter was shown for a 500-volt system. It places street railway managers in possession of data that heretofore could only be approximated.

The G. E. arc lamp display included some new features. The enclosed long burning arc lamp for alternating currents is giving excellent satisfaction, and appears to have solved the problem of producing a noiseless arc lamp for these circuits; it can be adjusted to any frequency or voltage. The other lamps on exhibition were the 80-volt single solenoid enclosed arc lamp, which can be adjusted for three or five amperes. One of the newest types of Wirt lightning arresters was also shown.

THE CENTRAL ELECTRIC COMPANY, Chicago, had on hand a full line of overhead and other street railway material; also the well known Billings & Spencer drop forged commutator segments, Bound Brook trolley wheel bushings and the Central Clincher ear. The last mentioned specialty has some unique features, as it is so constructed that the edges have only to be hammered a little toward each other and the trolley wire in groove will remain fixed securely in its place, without any soldering. They also showed the Syracuse changeable electric headlight and had some Lundell fans which they handle in operation, and the breezes which they wafted around the gallery of the city hall were extremely refreshing. The Central Co. were very worthily represented by Mr. C. G. Burton and W. P. Upham.

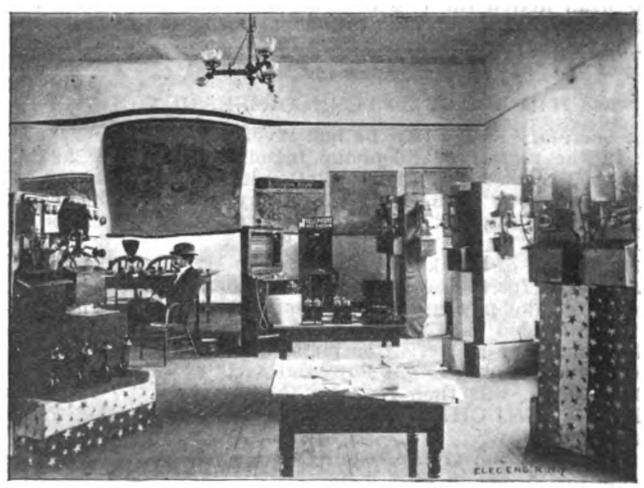
PASS & SEYMOUR, of Syracuse, N. Y., had a line of some of their porcelain specialties, including cleats, rosettes, branch blocks with fuse in cap, china key and keyless sockets, and also their porcelain junction box for primary circuits. This box, which has several new features, attracted considerable attention. Mr. J. D. McIntyre was in charge.

THE ELECTRIC APPLIANCE COMPANY, Chicago, had on view a line of Packard incandescent lamps, Highland's soldering paste, sample boxes of which were distributed among the visitors. Also a line of electrical heating goods manufactured by the American Electrical Heater Company, of Detroit, including smoothing and soldering irons. Several of the visitors who had their tiles or straw hats crushed had only to hand them to Mr. Frank McMaster, one of the representatives of the company, who ironed them over in first class laundry style. A most interesting feature of this exhibit was one of Newgard's waterproof globes, in which was enclosed a lighted incandescent lamp, the outer globe being totally immersed in water during the two days of the convention, without any of the liquid penetrating to the lamp. The genial president, Mr. W. W. Low, was, of course, present, as a function of the kind would not be complete if he were absent, and he was also one of the two fortunate recipients of titular honors conferred on the eventful occasion upon a pair of Chicago's most esteemed citizens.

THE AMERICAN ELECTRIC HEATING CORPORATION, of Boston, were represented by their Chicago manager, Mr. F. P. Luther, who had on view an extensive line of the goods made by this company, among which were 4 and 6-pound flat irons for laundry work; five o'clock tea kettles, kettles for boiling cereal foods; disc stoves, stew pans; an electric heating pad to take the place of hot water bottles, an electric immersion coil, which will do any cooking that a steam coil will do, and also one of their new Universal enamel rheostats, which they claim to be the best thing of the kind on the market at the present time.

THE ELECTRICAL SUPPLY COMPANY, of Madison, Wis., had a full line of supplies, special attention being paid to Columbia incandescent lamps, Grimshaw, Raven core, and rubberite wires, American tubes and insulators, Standard telephone and telephone supplies and sundries. Mr. L. W. Burch, the energetic president of the company, was around talking supplies, and helping to make things generally lively, in which attempt he was ably assisted by Mr. L. C. Hackney.

AMERICAN ELECTRIC TELEPHONE COMPANY.—To the regular attendants at the electric light conventions the size and handsome appearance of the exhibit of the American Electric Telephone Company, of Chicago, was undoubtedly a surprise from the fact that hitherto the telephone manufacturing companies do not appear to have thought it quite necessary for them to pay much attention to the conventions where central station men assemble. It would appear from the amount of telephone apparatus which the American Company showed at the convention that they were perfectly cognizant of the fact that lighting conventions were worth being attended by the telephone manufacturers. Among the large variety of telephone apparatus shown was that of the combined district and messenger system, which had not been exhibited before. The American Company has lately secured control and made arrangements for its adoption by the



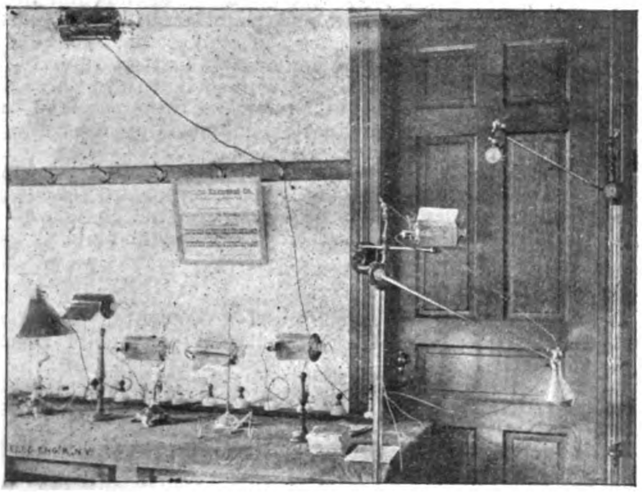
American Electric Telephone Mfg. Co.'s Exhibit.

city of Pittsburg and other towns. There was a display of about one dozen different types of telephones, and the cabinet work was quite varied. There were also two new types of portable desk sets, an elaborate sound-proof telephone booth, and among the other novelties shown were the new adjustable transmitter arm, new combined fuse and carbon lightning arrester, "express" type switchboard with automatic ringing device, automatic drop restoring feature, a new departure in the way of trunk line system for use in large exchanges; large magneto generator, and sundry other specialties in the telephone line. President P. C. Burns and Manager H. C. Dodge were indefatigable in their attentions to the numerous visitors to their fine exhibit.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, of St. Louis, was represented at the convention by Mr.

Eugene H. Abadie, who, with his usual courtesy, took pains to describe the different electrical appliances which they had on exhibition. These included a direct and alternating current motor, an alternating current ceiling fan motor, which was hung over their exhibit and served materially to keep cool the large room in which the exhibit was located. They also showed a line of switches, transformers and station instruments. Each visitor to the exhibit was presented with a neat souvenir button on which was shown a front view of the company's factory at St. Louis.

THE PACIFIC ELECTRIC COMPANY, La Crosse, Wis., had a full line, consisting of about ten different styles of the Espersen adjustable shade lamps; they also showed the Espersen dental and surgical lamps, and the Espersen eye, ear,



PACIFIC ELECTRIC CO.'S EXHIBIT

nose and throat lamps for medical examination. This company's shade lamps are noted for their ease of adjustability and simplicity of mechanical construction. This company is also prepared to furnish these lamps in different styles of finish and color to match the furnishings and surroundings of a room. The Ericson automatic bicycle bell is also manufactured by this company. Messrs. Haskell, Withee and Arthur F. Espersen had charge of the exhibit of this company.

MR. CHARLES C. SCHUMACHER and MR. ALBERT ZAMEL, of Chicago, were on hand and showed one of the new Zamel arc light meters and electric current timers. This instrument is a simple device, consisting of a balance wheel on a shaft on which is also placed a cog wheel, which works a toothed lever that serves to start and stop the clockwork movement which registers the length of time during which the arc lights are being used. The front of the instrument has a face similar to a clock's on which are shown the number of hours that the lights are in operation. All parts of the instrument are mounted on slate and perfectly insulated.

THE NEW YORK INSULATED WIRE COMPANY were represented by their genial Western manager, Mr. James Wolff, who was indefatigable in his efforts to assist in making the convention meeting successful, and at the same time had a sharp eye to business. Mr. Wolff had the good fortune to have a titular honor conferred upon him, together with the worthy president of a large Chicago supply house, and it is greatly to the credit of these two gentlemen that they received their honors with that innate modesty which is so thoroughly inbred in both.

IT was a matter of regret that one of the old representatives of the Fort Wayne Electric Corporation, who have been in the habit of attending these Northwestern conventions, did not get to La Crosse, but this company selected a very good substitute when they sent Mr. E. F. Kirkpatrick, of their Chicago office, to look after their interests.

THE PEOPLE'S ELECTRIC COMPANY, of Madison, Wis., was very ably represented by President F. H. Ford and Secretary C. W. Bacon, who were most energetically engaged in pushing for business for their progressive concern, and at the same time participated heartily in the entertainment features of the occasion.

THE LESHER-MACOMBER-WHYTE COMPANY, Chicago, had their Mr. George S. Whyte on hand. Mr. Whyte's abilities as a business man or as an entertainer with stories or song are too well known in the West to require any further comment; suffice it to say that he acquitted himself on this occasion with his usual success.

THE SIEMENS & HALSKE ELECTRIC COMPANY were represented by Mr. T. Julian McGill, who was very actively engaged in attending to the interests of the company, and made quite a number of friends at the convention.

THE CARBON manufacturing companies were well represented and had the following present: National Carbon Company, Cleveland, M. L. Stevenson, Chicago and Northwestern agent;

Standard Carbon Company, Cleveland, W. O. Connor; Crouse-Tremaine Carbon Company, Fostoria, O., J. S. Maurer.

There were also in attendance the following: Herman Andrae, Julius Andrae & Sons, Milwaukee; W. D. McDonald and W. F. Benton, Benton & McDonald, La Crosse; C. A. Ross, Sawyer-Man Company, Chicago; R. N. Loper, New Haven Car Register Company, New Haven, Conn.; B. E. Edwards, president La Crosse Electric Railway Company; James J. Hogan, president La Crosse C. B. E. L. & P. Company.

THE BUCKEYE ELECTRIC COMPANY, Cleveland, Ohio, were represented by their Chicago manager, Mr. J. H. Cooke, who showed a full line of incandescent lamps, manufactured by this concern. Mr. Cooke also had on hand some handsome arc lamps for various systems, manufactured by the Jandus Electric Company, Cleveland, Ohio. Of the type of lamp used on the direct current system more than 17,000 are now in daily service, and nearly all the Edison central stations throughout the country use the Jandus lamp exclusively.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY exhibited a 5 horse-power, 220-volt shunt wound, slow speed multipolar motor, which was shown in operation, and attracted considerable attention. They also showed an alternating constant potential 15-ampere, 26-volt arc lamp, which operates from an economy coil for an incandescent circuit. It is of an ornamental design, and is suitable for lighting stores, buildings or residences. They also had on hand an automatic circuit breaker for protecting direct current circuits; also Wurts's lightning arresters, ampere and wattmeters, transformers and fuse boxes. Mr. Henry Floy had charge of the exhibit.

THE COLUMBIA INCANDESCENT LAMP COMPANY, of St. Louis, were represented by Mr. A. C. Garrison, and had samples of some of their make of lamps, and also showed specimens of the liquid used in making filaments, as well as samples of threads, and the manufactured filaments. Mr. Garrison also gave souvenir buttons on which were shown a picture of one of their makes of lamps.

FOURTEENTH MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS AT GREENACRE, ME.

FIRST DAY.

THE fourteenth general meeting of the American Institute of Electrical Engineers was held at Greenacre-on-the-Piscataqua, near Eliot, Me., on July 26, 27 and 28, under unusually interesting circumstances, the society having accepted the invitation of Miss Sarah J. Farmer to visit Greenacre and assist at the jubilee of the electrical work of her distinguished father, Prof. Moses G. Farmer, whose first electrical undertaking, a short electric exhibition road, was put in operation at Dover, N. H., just fifty years ago. Owing to the remoteness of the spot, from most electrical centers, it was not expected that the attendance would be large, but it was believed by the Institute Council that the occasion was peculiarly one at which it should be represented. Prof. Farmer was a charter member, and afterward an honorary member, and took deep interest in the growth of the Institute. Its earlier existence would probably have led to the publication of many of his researches, which, for lack of such a channel of publicity, were allowed to lie in his thickly accumulated notebooks.

The meeting was called to order in the Eirenion Hall, on the Greenacre grounds, at 2 p. m., by Prof. F. B. Crocker, president, when Mr. C. P. Steinmetz presented a highly interesting paper on "The Alternating Current Induction Motor."

This paper gave the results of tests on polyphase induction motors. The paper embodied a series of curves showing the relations of speed, efficiency, power factor, current, output, etc., for a variety of conditions which arise in practice. Mr. Steinmetz discussed these curves and showed what is necessary and what must be avoided to obtain the best results in polyphase induction motors. A table of data on such motors, actually constructed, was included in the paper.

The paper was discussed briefly by Profs. Thomson, Goldsborough, Perrine and Kennelly.

PROF. ELIHU THOMSON then read a paper, entitled "A New Form of Induction Coil." He described a new type employing the principle of a "substitute primary," or "secondary primary," already applied by him in a variety of ways. This coil can be used direct on high potential circuits without the

use of banks of lamps or storage batteries. It is intended more particularly for Röntgen ray work.

The paper was discussed by Messrs. Marks and Kennelly. The regular afternoon session of the Institute then closed.

MONDAY AFTERNOON.

The afternoon was given up to the meeting called in the programme of the Electrical Conference that had been organized by Miss Farmer, to continue during the week of the Institute meeting. The opening session was intended as a memorial to Prof. Farmer, and was held in the large tent on the grounds, when the conference convened under the direction of Prof. Cyrus F. Brackett, of Princeton, who addressed a large audience on the subject of "The Past and Present Outlook of Electrical Science." It was a very able condensation of electrical advance as embodied in scientific history and as expressed in the adoption of succeeding ideas and theories or principles as to the nature and physical relations of electrical phenomena.

PROF. A. E. DOLBEAR, of Tufts' College, followed with an address on "Moses G. Farmer as an Electrical Pioneer."

Prof. Dolbear gave a most graphic review of Mr. Farmer's life and work, and brought out the fact that he combined harmoniously the theoretical and practical sides. He thought with the late F. L. Pope that modern electrical engineering ought to date from the Farmer beginnings, the only predecessor being the Morse telegraph. Indeed, Prof. Dolbear seemed to think that the honors had been distributed very unequally. "Morse, who did nothing electrical, had his front shingled with European decorations and his bronze image sits in Central Park." As to Farmer, "he himself did not herald his inventions. Those who profited by them were content to pocket the receipts and say nothing; and men of science ignored him. First he did not belong to the schools, and, second, it was not thought by them to be proper for a scientific man to patent his inventions. Dartmouth College honored him with an A. M., which is absurd, when a callow graduate can get one by a year of work, which, in itself, amounts to nothing." One trouble with Mr. Farmer was that, unlike Faraday, he did not publish his experimental work, whether with or without result. In the files of Farmer's notebooks, there were not less than 15,000 pages filled with most valuable records and suggestions. So completely did Mr. Farmer cover the electrical field in inventions that almost every one who has applied for a patent for what he took to be some electrical novelty has been referred to Mr. Farmer's prior inventions as embodying it; in spite of which much, as will be seen, was left unknown. Prof. Dolbear, in conclusion, showed how early Farmer did much of his work, and he made the broadest claims for his priority in the lines of fire alarm telegraphy, railway work, quadruplexy, self-exciting dynamos, incandescent lighting, practical thermopiles, torpedo work, and many other fields. The address was received with very hearty and prolonged applause.

MR. W. J. HAMMER, by request, then read a very interesting letter written to him by Prof. Farmer, just before his death in 1893.

MONDAY EVENING.

The evening session of the Institute was held at the Eirenion, which was crowded by members, and Greenacre folk. Miss Farmer made a brief address of welcome and then delegated the task of the formal address to her father's friend, Prof. G. F. Barker, of the University of Pennsylvania, who delivered a charming speech full of reminiscences of Prof. Farmer, extending over a great many years, beginning with the youth of the speaker. Prof. Barker took occasion to emphasize the evidence of the priority of Prof. Farmer's work in regard to the principle of self-excitation.

PROF. CROCKER responded on behalf of the Institute, acknowledging the compliment. He spoke of Prof. Farmer as being in many respects the ideal electrical engineer, combining ability to grasp principles, skill in applying them, in original apparatus, and a thirst for definite data on all things in his field. He then went on to deliver his inaugural address on "The Precision of Electrical Engineering." The address championed electricity as one in regard to which, outside the mystery of its nature, we could get more definite ideas as to its work and effects than of any other agency employed by man. He thought that even if we knew what electricity was, it would make little difference, except, perhaps, in the generation of current. Most of the utilizations would probably remain pretty much the same. He went on to show how wide are the margins and "safety factors" required in other engineering work, and how much of the cut-and-try still remains. In electricity, the largest and smallest apparatus was now closely predetermined within a small percentage, and the calculations made by any competent man would prove sharply precise and accurate. Prof. Crocker instanced a number of striking instances of precalculation, of fine measurement, of close detection of "faults," and other features of precise dealing with the facts and conditions. He referred also to the precision of engineering electrical terms and units, and their universal acceptance, while in other fields a variety of confusing terms and units still existed everywhere. As to the manner in which the present age had developed electrical ideas to the limits, Prof. Crocker said that both Mr. Edison and Mr. Tesla had lately intimated to him that they were more interested in chemistry and in steam engineering because there was more uncertainty, and therefore more chance to improve things than now existed in the arts of electricity.

MR. W. S. KEY, at the close of the address, read by request two letters of Prof. Farmer written at the time of the Dover electric road in 1847, exactly fifty years ago that very night. One letter was to a local poetical celebrity, asking him to get up some verses on the event and bring along his melodeon. The other letter was to Charles Carleton Coffin, speaking of the work on the road, and among family matters referring to Miss Farmer's birth. The letters were delightfully naive and earnest, with many touches of humor, and were received with frequent outbursts of applause. The meeting closed as it opened with excellent music.

A resolution was offered by Mrs. K. T. Woods and seconded by Prof. Thomson that some steps be taken toward founding a permanent memorial of Prof. Farmer, and the chair was instructed to form a committee with that end in view.

TUESDAY MORNING.

DR. A. MACFARLANE'S paper on the "Application of Hyperbolic Analysis to the Discharge of a Condenser" was read, and was discussed by Messrs. Steinmetz, Kennelly, Perrine and Bell.

MESSRS. P. A. BATES and W. C. BARNES then presented in person their paper on the "Effect of Heat upon Insulation."

The paper gave the continuation, as it were, of the experiments made by Messrs. Lever, Monell and Perry, read at the last annual meeting. The results correspond in the main with those previously obtained. It is shown that the presence of brass in the testing apparatus does not affect the results, which depend solely on the amount of moisture and its opportunity of escape. The resistance increases every time it is heated and cooled, provided it is kept from absorbing moisture. Red insulating fiber was used in the experiments.

The paper was quite fully discussed by Messrs. Crocker, Perrine, Estey, Steinmetz, Thomson and Kennelly.

PROF. W. E. GOLDSBOROUGH then read a paper on "The Effect of Armature Inductance upon the Electromotive Force Curves of an Alternator," which was discussed after dinner by Messrs. Dunn and Steinmetz.

In this paper Prof. Goldsborough embodies the results of experiments made with an exploring coil in connection with a 3-light Brush arc machine. The results are plotted in curves which show the voltage obtained at different positions of the exploring coil under varying conditions of current strength, etc.

During the morning session a group photograph was taken at the Eirenion. The original Farmer locomotive and car sent on by the Smithsonian Institution were placed in the center, with Miss Farmer and her father's portrait at the back. On the locomotive was pinned one of the original posters announcing the opening of the road and inviting the public.

TUESDAY AFTERNOON.

MR. C. P. STEINMETZ presided over the afternoon session.

MR. CARYL D. HASKINS read a very interesting paper on "Electrical Metering from the Station Standpoint."

In his paper Mr. Haskins laid down the principal requirements of a good meter. He showed that mere ability to start on a very small load did not make up the sum and substance of a good meter, but that for all-round utility other qualities were necessary and desirable. He gave a number of valuable hints to station operators as to the best method of handling meters, where to look for the meter tamperer's work, etc. He also expressed the belief that the penny-in-the-slot meter had a great future before it.

DR. LOUIS BELL gave an interesting discussion of the paper and expressed his strong belief in the coming prevalence of direct reading meters that would give the watt hours where every user could read and see them, rather than be puzzled by a set of wheels running up a charge against him in some weird and suspicious manner. The paper was also discussed by Messrs. Perrine, Owens and Haskins, along the line of the practical aspects of the question.

The Greenacre Conference in the afternoon listened to a charming address from PROF. G. F. BARKER, on the work of the Philosophical Society. This was followed by a very happy description from MR. A. E. KENNELLY, on the nat-

ure, conditions, successes and perils of submarine cable work. He told graphically of one operation he had been engaged in on the English-Lisbon cable. They were repairing a break and actually had the cable raised and on deck, when desiring to get a few more feet they tried to do so. On a sudden, the cable snapped and slid slowly off the deck, nobody, of course, being able to avert the disaster of losing it again after long toil. A sailor almost instinctively put his hands on it to stop it, but such an effort was obviously useless.

TUESDAY EVENING.

MR. ADAM BOSCH read a paper, entitled "A Historical Sketch of the Fire Alarm Telegraph," and gave in it a very complete review of the advance and growth of that useful system from the time of Farmer and Channing down to the present day.

Discussion was contributed by Prof. Barker and Miss Farmer.

A paper was then read from MR. M. H. GERRY, JR., entitled "Electric Traction: Notes on the Application of Electric Motive Power to Railway Service," with illustrations from the practice of the Metropolitan Elevated Road, of Chicago. In the absence of the author the paper was read by Secretary Pope.

The author traced the various efficiencies of the transforming steps from generator to car axle, and brought out in a striking manner the power required for acceleration of elevated trains, which, in the case of the Metropolitan Road, required 63.9 per cent. of the total power, with only 29.1 per cent. for train resistance and 7 per cent. for grade. Mr. Gerry holds that electricity has well established its claim to economy and adaptability to railroad traffic. The paper was elucidated by numerous curves, showing the behavior of the motors under varying loads, speeds, etc., and also by current diagrams covering an entire trip.

A brisk discussion arose between Messrs. Perrine, Steinmetz, Crocker and Thomson as to the features of accelerating, coasting and retarding a train, and on the distribution of the kinetic energy required to get trains from station to station. Mr. Steinmetz described the new London Central subway road, where to assist acceleration trains will leave stations on a good down grade, will then coast, and have retardation assisted by a good up grade to the short level at the station.

WEDNESDAY MORNING.

Prior to the opening of the morning session, a visit was made by many of the members to the Farmer homestead, at Eliot, about a mile from Greenacre through the pine woods. The quaint, old-fashioned house is not only full of family mementoes and relics of colonial and revolutionary ancestors, but brims over literally with evidences of the ceaseless electrical work and study of Prof. Farmer. Not only did he use three rooms in the house for study and experiment, the traces and signs of which are religiously preserved by his daughter. but there is an annex laboratory in a large barn, chock full of old apparatus, bearing all the earmarks of frequent and various use, and which the large exhibit at the Eirenion did not appear to have at all depleted. Mr. Keefe, who had long served as Prof. Farmer's assistant, and who is now one of the trustees of the estate, was most interesting and helpful in explaining the different pieces and in telling of Prof. Farmer's ideas and plans. Some of the apparatus is going to the Smithsonian Museum at Washington, but it is an open secret that Miss Farmer proposes to entrust some of it to the Institute; to whom it has also been suggested that a volume issued under its direction, composed of Prof. Farmer's most important notes and observations would be as worthy an effort as its publication of the proceedings of the Electrical Congress of 1893. After the trip, the members returned to the Eirenion and the regular sessions began.

MR. HORATIO A. FOSTER presented a paper on "The Cost of Steam Power."

In this paper Mr. Foster embodies the results of an extended investigation covering widely different types of industry and conditions of operation. He tabulates and discusses in detail twenty-two plants investigated, varying from 12 h. p. up to 2,422 h. p. in capacity. The variations of cost shown are very great, even in plants of the same general type, so that it is almost impossible to generalize. Taking large compound condensing engines, however, he finds the cost to be $.00824 per h. p. hour. The average of other investigators of repute is $.00705. The paper was replete with valuable data on the cost of steam power and what ought to be included in such an estimate. A diagram included in the paper, due to Mr. L. B. Stillwell, showed the cost per h. p. for any given case.

PROF. PERRINE made the point that the best fuel is that which yields the cheapest steam, and he gave an interesting account of fuels on the Pacific Coast.

PROF. THOMAS said that the best recent work in this line was a paper by Prof. Lord, read before the Mining Engineers, and not yet out. It would be found thoroughly exhaustive and very useful.

MR. POPE called attention to the economies in fuel now effected, as shown by the fact that pea coal and others now on the market were utterly neglected as waste a few years ago.

PROF. OWENS said the best way to get at it was to figure out the pounds of water evaporated for every dollar's worth of coal. He pointed also to the high relative importance of lamp breakage, as an item comparing against fuel outlay.

MR. BURNETT as a central station man approved the high value of the Foster data.

MR. RIPLEY told of a practical experience on Long Island where an engineer wanting to burn coal of high calorific value had lots of trouble with his directors because of the apparent high price.

PROF. OWENS as special commissioner from the State of Nebraska invited the society to hold its next meeting in 1898 at Omaha, during the continuance of the Trans-Mississippi Exposition there.

MR. MARTIN urged strongly the going West, and pointed to the remarkably liberal expenditure of Nebraska in education and for technical training. This should be recognized and encouraged. He offered the following, which was forcibly seconded by Mr. G. S. Dunn, and supported by Messrs. Steinmetz and Pike, while Mr. Pope mentioned that the Institute had received other invitations:

"Resolved, That it is the sense of this meeting that it is desirable to hold the next general meeting of the Institute at Omaha, and that the invitation extended by Prof. Owens be favorably referred to the Council for further consideration and early action." The resolution was unanimously adopted.

PRESIDENT CROCKER made an informal report of the successful adoption by the National Conference on the subject, of which he was a member, of the National Code of Wiring Rules. After a discussion as to the propriety of anticipating the acceptance and approval of the Rules by the Council, the meeting voted not to take any action of its own on the matter other than the presentation to it of Prof. Crocker's report.

MR. W. H. FREEDMAN'S paper on "Efficiency and Life of Carbons in Enclosed Arc Lamps" was then presented.

The author and his assistants tested seven different makes of enclosed lamps as to regulation of arc, life of carbons, candle-power, etc., and find that the enclosed lamp has the following advantages over the open arc: Long life and consequent saving in carbon, trimming expenses, etc.; pleasant light, freedom from hissing; absence of flying dust and sparks; no danger from high potentials, and no need of automatic cut-out; simplicity of mechanism.

Mr. Freedman's paper was discussed by Messrs. Kennelly, Owens, Crocker, Marks, Spaulding, Steinmetz and Rittenhouse. The session then adjourned.

During the morning session a special dispatch of 300 or 400 words to Miss Farmer of congratulation from Mr. Frank J. Sprague was read by the recipient. Mr. Sprague, who was at Schenectady testing his new system of electric traction, described elsewhere in this issue, and who was an old friend and Newport naval student under Prof. Farmer, said he was glad to associate his work with that of the pioneer under such auspicious circumstances.

PROF. R. B. OWENS then read an interesting paper, entitled "Armature Reactions in a Rotary Transformer." He pointed out that the increasing use of rotary converters in power distribution makes it necessary that all points relating to their design be studied with the same care and exactness that standard forms of alternating and direct current apparatus have received. It has been known that the armature reactions in rotary converters are comparatively small, but exact quantitative measurements have been wanting. In the paper presented by Prof. Owens, the exact instantaneous distribution of induction over the pole faces of a rotary converter under different conditions of loading and different armature positions is plotted as a series of curves, which show in an exceptionally clear manner the shifting of induction in amount and direction as the armature rotates. Curves were also given showing the armature reactions of the machine operating as a simple direct current motor; comparing which with the curves of instantaneous induction distribution when operating as a conoverter the relative amount of armature reaction of the same machine operating in the two ways is clearly shown. The data obtained will be of use in many ways. The general method employed to measure instantaneous induction values was by measuring the instantaneous e. m. f.'s generated in a series of equal evenly spaced test coils of fine wire wound over the armature surface. The contact maker is especially good. The zero telephone method was used in

measuring e. m. f.'s, which allowed of accurate measurement of 1-50 volt.

The Owens paper was discussed by Messrs. Crocker, Goldsborough, Dunn, Steinmetz and Elihu Thomson.

Before the work of the convention closed, a committee, composed of Messrs. Pope, Crocker and Owens, was appointed to draw up resolutions thanking Miss Farmer for her kindness and hospitality.

AFTERNOON AND EVENING SESSION.

At the afternoon meeting of the Greenacre Conference, Dr. F. A. C. Perrine gave a very suggestive address on "The Altruistic Aspects of Electricity." He pointed out that electricity was a vital factor in social economy and economies, and that all the aims of electricians were directed toward improving apparatus and lessening costs. Thus, they were constantly bettering things all around them. The value of electric light in lessening vice and crime outdoors, and in ameliorating conditions indoors, especially in workshops, was alluded to, and it was also noted that a further hygienic gain came in from the resort to electricity in chemical manufactures. In the uses of electrical power many beneficial social changes were also found, ranging from the diminution of smoke to the reduction of bad elements in the factory system.

PROF. ELIHU THOMSON at the evening Conference gave an address, with wonted charm and felicity, on "The Future of Electricity." Like Prof. Brackett, he is not to be counted among the pessimists who think that the possibilities of electrical development are used up.

PROF. F. P. JACKSON'S paper was the last on the Institute programme, and was entitled "The Economy and Utility of Electrical Cooking Apparatus." He made comparative tests of the cost of cooking and ironing for a family of six for several weeks. Taking the cost per k. w. hour at 10 cents and coal at $5 per ton, he finds that cooking by coal costs about 19 per cent. of that by electricity. Ironing by coal cost 54 per cent. of that by electricity. The results seem to indicate that ordinarily the cost of electric cooking would be prohibitory; but there are many situations in which countervailing advantages would make electric cooking desirable.

The Jackson paper was discussed by Messrs. Thomson, Owens and Pope.

CONVENTION NOTES.

A very interesting exhibit was made of some 400 or 500 photographs, framed and unframed, relative to electric railway work, and loaned for the occasion by the General Electric Company, the Walker Manufacturing Company, the Westinghouse Electric and Manufacturing Company, the "Street Railway Journal," The Electrical Engineer, Prof. Elihu Thomson, Prof. S. H. Short, Mr. W. J. Hammer, Mr. T. C. Martin and others. These were displayed on long tables and on the walls, and were carefully labeled with explanatory references so as to be readily understood. They showed the whole range of the art during the last ten years of rapid commercial development, and were representative of roads and apparatus in all parts of the world. Portraits were also shown of men active in the work. This photographic exhibit was supplemented by a beautiful collection of electrical portraits, loaned by Mr. Hammer, and including also some of his data and relics relative to Prof. Farmer. The exhibit and that of Prof. Farmer's papers and apparatus were in charge of Messrs. Key, Keefe, Martin and Hammer.

The Farmer collection was extremely interesting and comprised a large variety of experimental and perfected apparatus, chiefly from the Farmer laboratory at Eliot. It was necessarily far from complete, but gave a good idea of the inventor's range and versatility, including telegraphs, motors, generators, thermopiles, fire alarms, torpedo apparatus, batteries, measuring instruments, etc. With this were shown many relics, autographs, photographs, biographical articles, and two excellent oil portraits of Prof. Farmer and his wife.

The attendance while naturally small of those directly interested was highly representative, and all parts of the country were included. Among those present were W. C. Andrews, Dr. Louis Bell, C. T. Bancroft, Prof. C. F. Brackett, Princeton University; Putnam A. Bates, Adam Bosch, D. Burnett, R. G. Brown, Prof. G. F. Barker, University of Pennsylvania; J. H. Craig, C. T. Childs, A. E. Childs, Prof. F. B Crocker, Columbia University, N. Y.; G. A. Damon, G. S. Dunn, Prof. A. E. Dolbear, Tufts' College; Prof. W. Estey, Urbana; C. L. Edgar, Prof. W. E. Goldsborough, Lafayette University, Ind.; F. W. Hadley, Caryl D. Haskins, G. A. Hamilton, W. J. Johnston, W. S. Key, Francis Keefe, T. C. Martin, L. B. Marks, Prof. R. B. Owens, University of Nebraska; N. W. Perry, Clayton W. Pike, Prof. F. A. C. Perrine, Leland Stanford, Jr., University, California; R. W. Ryan, Almon Robinson, C. T. Rittenhouse, W. H. Ripley, C. P. Steinmetz, C. K. Stearns, H. C. Spaulding, Prof. Elihu Thomson, H. Wray Weller, W. D. Weaver. Some of those present were accompanied by members of their family, and there were, of course, a large number in attendance at the Institute meetings and the Conferences from the resident population of Eliot, Me., and from those sojourning at Greenacre for the studies and recreations of the season.

Nothing could have been more agreeably enthusiastic than the reception accorded the Institute at Greenacre by Miss Farmer and her friends. The Inn being unable to accommodate all, Mrs. Ole Bull received several into her cottage, while others went out into tents in breezy Sunrise Camp. The weather was fine as a general thing, and the pleasure of the occasion was thus greatly enhanced. There were several local committees of ladies to attend to various matters, and the work of those who assumed secretarial duties must be specially commended.

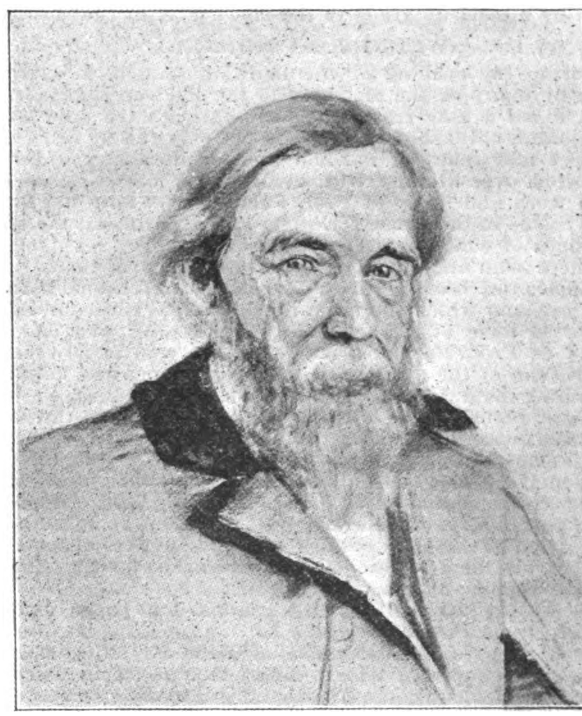
The committee selected to take in hand the Farmer Memorial consists of Mrs. Ole Bull, Mrs. Kate Tannott Woods, Prof. G. F. Barker, Prof. A. E. Dolbear and Prof. Elihu Thomson. Nothing definite has been chosen yet, but a scholarship is seriously under consideration.

PERSONAL

PROF. MOSES G. FARMER.

A detailed sketch of Prof. Farmer, whose electric railway jubilee was celebrated at Greenacre, Me., last week, was given with portrait, by Mr. Franklin L. Pope, in The Electrical Engineer of May 31 and June 7, 1893, and need not be here gone into as elaborately.

The life work of Prof. Farmer was admirably summed up by Prof. Dolbear, at Greenacre, in his memorial address. At 26 he had built an electrical railroad. At 28 he had improved the telegraph. At 30 he had invented and constructed his fire alarm system with water-power driven dynamos. At 35 he had discovered the means for duplex and quadruple telegraphs. At 36 he invented the art of depositing aluminum electrolytically. At 39 he lit his parlor in Salem with incandescent lamps. At 44 he had greatly improved thermo-electric generators. At 46 he had been the first to invent the modern dynamo with self-exciting field. At 48 he lit a house, in Cambridge, Mass., with 40 incandescent lamps in multiple cir-



PROF. MOSES G. FARMER.

cuit, and all properly self-regulating. Prof. Dolbear thought also that there was good reason for believing that he was to be credited with the introduction of the condenser into telegraph

Miss Sarah J. Farmer.

work. We supplement our portrait of Prof. Farmer with one of his public spirited and philanthropic daughter.

NEWS AND NOTES

THE NEW SPRAGUE MULTIPLE UNIT SYSTEM OF CAR TRACTION.

An important demonstration in electric railway work was made at Schenectady, on the experimental track of the General Electric Company, on July 26, when a number of prominent railroad men met to watch the test of Mr. Frank J. Sprague's new multiple unit system of electric car propulsion.

The keynote of this system is the individualizing of cars in all details. Its object is to so control them that they can be connected together at will, and, when so connected, operated from either end of any car in the train unit. It thus stands in broad contrast to the two systems hitherto in vogue, the individual car equipment, as in ordinary street service, which had its precursor at Richmond, and the locomotive car equipment, pulling trail cars. The last is represented on the Nantasket line, the Metropolitan West Side and Lake Shore Elevated Railroad, at Chicago, and, with the difference that steam is used instead of electricity, is in use on the elevated roads throughout the country.

It is a curious fact that prior to the inauguration of the present trolley system, in 1886 and 1887, there was built for the Sprague Company a car, which was designed to be operated as a locomotive car. It was a full-sized elevated railroad car having double trucks, 42-inch wheels, inverted half-elliptic spring suspensions, with enclosed vestibules at each end, for the motorman, and a central smoking cab. This car was to have been equipped with four 75 h. p. motors, but it was never finished. It was before its time. It afterward passed into the hands of the General Electric Company, and was kept in the yard at Schenectady. This car has since been fitted with motors, and used for traction experiments on the G. E. private track. By a singular coincidence, the new Sprague equipment has been delivered on the tracks alongside of it, eleven years after its too early evolution.

The experimental train consisted of six standard cars of the South Side Elevated Railroad, Chicago, each of which had at one end a McGuire truck carrying two "New 57" G. E. motors, of a normal capacity, of 50 h. p. each, and tested to over 100 h. p. The cars were all equipped with the new Sprague multiple unit system of control, by which any car is operated from either end by a lever or push button, with automatic return, something after the method of the Sprague elevator. The details of this system have not yet been made public, but the results obtained are interesting. By its application, any number of cars, without regard to sequence or heading, may be coupled together, and, when so coupled, instantly controlled from either selected end of any car.

Controlling mechanism is carried on five cars enclosed underneath the seat inside the car. In one car it occupies the unique position of a space inside the canopy over the platform, where it can be reached by an inspector without entering the car. Underneath each car is a small cable terminating in a flexible end, with a peculiar interlocking coupling, which, no matter what the heading of the cars may be, so connects the controlling circuits, that the same directional movement of the controller on the platform always produces the same movement of the car with regard to the track. There is, therefore, no such thing as a head or tail of the car. The establishment of this coupling takes less time than the coupling of a single pipe in the ordinary air-brake system.

The visible controlling agency on the platform consists of a round box, carried on an upright, on the face of which is a movable lever, which turns in one direction or the other, and through various degrees of arc. It also, according to the time of contact on certain sections of the arc, gives the forward and backward movements, and all variations of speed. Whenever the power is on the machine, the operator who wishes to put the car in motion, must at all times retain his hold of the controlling lever. If he lets go the controlling apparatus is immediately brought to the position of "off," and the power is cut off from the car. The action of this controller on the regulators of all the cars is instantaneous. It matters not whether the operator is standing in the middle of the train or at the end, there is a simultaneous movement of the regulators in each car through all the gradations of control. Each train is also equipped with a circuit breaker, and an automatic air compressor. It is electrically lighted and will be electrically heated.

A special feature, illustrated in one car, is the new Sprague vestibule, an admirably effective and convenient arrangement, in which all the perplexing problems of the car vestibule appear to be easily and simply solved. It enables the operator on any ordinary platform to be enclosed, either wholly or in part, and gives him full view of the track both forward and backward along the train. He is at the same time within reach of his controller, air and hand brakes, and air gauge. When he leaves the vestibule, the platform can be immediately thrown open to serve for the exit or entrance of passengers.

The braking of the train is accomplished by the Westinghouse automatic air-brake, with an engineer's valve on each platform, closed by the motor regulators, and with air supplied by Standard automatic air compressors.

The action of the controller is remarkable. There is little, if any, more apparatus than on the standard street car, yet the extra hands, which are usually engaged in operating two or more such cars, coupled together, are replaced, under the new system, by an exceedingly ingenious mechanism. These automatic, electrical mechanisms are controlled at will or automatically by the motorman at the head of the train, each, however, exercising over its own motors an automatic supervision of such a character that it will not permit stupidity or carelessness on the part of an operator.

When the system, which is the fruition of prophecies made by Mr. Sprague, and which have been indicated from time to time by him, was proposed, much doubt was expressed as to whether a number of individual controls joined together would be sufficiently similar in operation to equalize, for all practical purposes the circuit on the various motors. Practice has shown that by novel automatic regulation each motor very largely takes care of itself in this respect, or, at least, makes its own controller do it, and it is found that practically equal duty is exercised at all speeds and loads by the motors on the different cars. To such an extent does this obtain, that although the operator has the privilege to retard acceleration, he is limited in his extent of it, and at will can, no matter what the load, make the motors throughout the

system each accelerate at its safe maximum by a single movement of the platform lever. In case of serious trouble to a machine, such as short-circuit or burn-out, the motors on that part of the cars will cut themselves out automatically, and the cars can be pulled along by the remaining cars of the system.

The controllers, also, are self-rectifying, inasmuch as, should the line current fail and then be restored, they will come back to the starting position before the circuit can be closed through the machines.

The practical possibilities of the system seem to be many. Suburban and elevated service, the latter particularly, where there is any attempt at high schedule speed, with frequent stops, is largely a problem of acceleration, the car being got out of the way as quickly as possible, run a short distance, and then allowed to coast. By this system a much larger proportion of the weight of a five or six-ton car train is available for brake purposes than where the same number of cars are pulled by a locomotive, there being an average of about 60 to 62 per cent. This makes it possible to run up to a total accelerating strain of at least 15,000 pounds per six-car train, and gives a rate of acceleration for the train exactly the same as in a single car—that is the train duplicates in all essentials in acceleration, speed and stopping rate, a single car. This system gives the railroad manager the utmost flexibility. He can operate at the shortest practical time intervals between trains, so as to get frequency of service, and yet he can increase the units to meet the requirements of the day to any amount. Cars can be run on branch lines coupled together, and others made up into trains of four, five and six cars on main lines, and afterward redistributed.

The automatic system of control lessens the maximum starting currents. It keeps the size of the motors well within the bounds of the size of trucks, which are generally limited both in width and wheel-base, and will have enormous value in increasing the traffic on the road, this being much more important than any saving of coal and attendance.

On elevated railroad structures the strains are very much reduced. Cars can be left out in siding or middle track and at any part of the road, and any number of cars can be run from either end of the battery without any head or tail switching.

On the night of July 25 a preliminary run was made, and on the 26th train units of one, two, three, four and six cars were operated at a speed as high as 33 miles an hour. The first time the car was sent down the track, the lever was started by Master Frank D'Esmonde Sprague, Mr. Sprague's nine-year-old son, who handled both the switch and the air-brake.

In the matter of the application of this system to the standard elevated railroad car, it may be said that it will entail no interference with the car at all, and the vestibule affects in no way the incoming and outgoing of passengers, while affording ample protection to the motorman.

The essential importance of the system is in enabling frequent time runs to be made instead of having intervals of from 45 seconods to 15 minutes, and train lengths of from three to five cars. The train units can vary from, say, one to six or more cars, all run at the same rates of acceleration and maximum speeds that can be attained with a single car, increasing, in a very material way, passenger schedule time with any fixed train schedule; because the passenger schedule is made up of two elements, waiting time at train stations and time of transit. As a rule, the traveler has only a limited distance to go, so that his own schedule may be very materially reduced from the train schedule by station wait.

The requirements of suburban service have not really been met heretofore, and the new system will go a long way not only to force the equipment of electric elevated trains, which are in direct opposition in the matter of frequency of service with trolley and cable systems, but also give an immense stimulus to suburban service.

The equipments for the test were gotten together in three weeks, the factories of the Sprague Company, the General Electric Company, of Schenectady and Lynn, the McGuire Manufacturing Company, of Chicago, and others being pushed to their utmost, and the work was rushed day and night. The first two cars were started July 16, and the number has been added to as the work progressed.

The leading features of the demonstration at Schenectady were the wonderful control and smoothness of operation of the system. The starting and stopping were equally prompt, and the train of six cars moved and was operated as if an individual car. The test was eminently successful, and it is understood that several large roads are very shortly to be equipped with the system. It is rumored that further important and radical innovations in railroad practice will soon be introduced in connection with the multiple unit system.

LETTERS TO THE EDITOR

THE LAKEWOOD, O., MUNICIPAL PLANT.

In your issue of July 22 we note an article relative to the alleged failure of the Lakewood, O., electric light plant. The article interests us this morning especially in view of the fact that the lights started last night, and to the greatest satisfaction of all concerned. We note that your article is based on quotations from a daily paper, and we should think that the statement that "the wires are rusting on the poles" would be sufficient to stamp the inaccuracy of the article. It is true that the contractor failed to complete his work, and that there was somewhat of a delay in straightening up the matter with the Security Company; nevertheless, the work has gone on, and there has not been the slightest hint as to mismanagement or corruption.

The superintendent suggested by us was engaged without reference to his politics, and, as a matter of fact, I do not even know what they are, nor the politics of any of the board of trustees. Although fully aware that many municipal plants are very badly managed, which is also the case with very many private plants, nevertheless, up to date the Lakewood plant has been entirely free from mismanagement and arrangements have been made which make it probable that such will be the case in the future. The water and coal will be measured, and we expect to criticise the operation and the bills. We appreciate your position against municipal management of electric light plants, but we also know that you do not desire to support your position by incorrect statements.

The article which you quote was only a matter of amusement to us until it was dignified by being referred to by you.

E. P. ROBERTS.

Cleveland, Ohio, July 24, 1897.

(We believe the facts were as we stated, but are glad to learn that the plant has at last got running.—EDS. E. E.

LEGAL NOTES

A TROLLEY INJUNCTION DISSOLVED.—THE U. S. CIRCUIT COURT OF APPEALS VACATES THE PRELIMINARY INJUNCTION AGAINST THE HOOSICK RAILWAY CO.

On July 21 the U. S. Circuit Court of Appeals reversed the decree of Judge Coxe and dissolved the preliminary injunction obtained by the Thomson-Houston Electric Company (General Electric Company) against the Hoosick Railway Company, for the use of the under-running trolley. By this action the Hoosick Company is permitted to continue the use of the trolley pending the trial of the suit.

We give below an abstract of the opinion of the court, written by Judge Wallace:

This is an appeal from an order granting a preliminary injunction restraining the defendant from making, using or vending the apparatus specified in claims 6, 7, 8, 12 and 16 of Letters Patent, No. 495,443, granted April 11, 1893, to the administrators of Charles J. Van Depoele, assignors to the complainant for "traveling contact for electric railways." The application for the injunction was resisted upon the ground that the patent as to these claims was void because the inventions covered thereby had been previously patented to the same inventor by Letters Patent, No. 424,695, granted April 1, 1890, for "suspended switch and traveling contact for electric railways." The validity of the claims, notwithstanding a similar defense, had been adjudicated at final hearing in the case of this complainant against the Winchester Avenue Railway Company by the Circuit Court for the District of Connecticut (71 Fed. Rep., 192). In granting the present injunction the court below followed that adjudication without attempting an independent consideration of the validity of the defense.

The question whether two patents are for the same invention is a question which is to be determined by a comparison of the documents themselves. Both patents originated in the application of Van Depoele, filed in the Patent Office, March 12, 1887. The application was divided, and while one of the

divisional applications was involved in an interference proceeding which delayed the issuance of a patent, the other divisional application culminated in the patent granted April 1, 1891.

The claims of the earlier patent are thirty-five in number, and are addressed more particularly to combinations between the conductor switches and the traveling contact; while the claims of the later patent, which are sixteen in number, are addressed more particularly to combinations between the traveling contact and the suspended conductor.

The five claims in controversy of the patent in suit are as follows:

"6. In an electric railway, the combination with a suitable track and a supply conductor suspended above the track, of a car provided with a swinging arm carrying a contact device in its outer extremity and means for imparting upward pressure to the outer portion of the arm and contact, to hold the latter in continuous working relation with the under side of the supply conductor, substantially as described."

"7. In an electric railway, the combination of a car, a conductor suspended above the line of travel of the car, a swinging arm supported on top of the car, a contact device carried by one extremity of the arm and held thereby in contact with the under side of the electric conductor, and a tension device at or near the other end of the swinging arm for maintaining said upward contact, substantially as described."

"8. In an electric railway, the combination of a car, a conductor suspended above the line of travel of the car, an arm pivotally supported on top of the car and provided at its outer end with a contact engaging the under side of the suspended conductor, and a tension spring at or near the inner end of the arm for maintaining said upward pressure contact, substantially as described."

"12. In an electric railway, the combination with a car, of a post extending upward therefrom and carrying a suitable bearing, an arm or lever carrying at its outer end a suitable contact roller and pivotally supported in said bearing, and provided at its inner end with a tension spring for pressing the outer end of the lever carrying the contact wheel upward, against a suitable suspended conductor, substantially as described."

"16. In an electric railway, the combination of a car, a conductor suspended above the line of travel of the car, an arm pivotally supported on top of the car and provided at its outer end with a grooved contact wheel engaging the under side of the suspended conductor, and a tension spring for maintaining an upward pressure contact with the conductor, substantially as described."

In considering the question whether both patents covered the same invention Judge Townsend in the Connecticut cause, speaking of the earlier patent, said: "The original application, filed March 12, 1887, claimed a spring and tension device so arranged as to impart upward pressure. The improved device showed a spring and weight so arranged as to permit lateral motion by the arm and to 'constantly tend to restore the arm to its normal central position and assist it to partake of the lateral movement of the car,' to give it a greater range of action and make it more convenient in operation. This patent for this specific combination adapted and claimed only for this specific purpose, applied for October 22, 1888, after the original application had been allowed but before the patent thereon had been granted, was earlier in the date of issue. The original application was delayed by interference proceedings in the Patent Office. Whatever may be the rule as to cases where the application for the general patent was filed subsequent to the application for the specific patent, I do not think the patentee should be deprived of his broad patent where the application for such patent was made first and was delayed in the Patent Office through no fault of the inventor."

With these conclusions we are unable to agree. We should concur if we could regard the later patent as the generic one, and the earlier, so far as it relates to the contact device, as limited to the structural improvements upon that device. But we are of the opinion that although the earlier patent contains matter of disclaimer inserted for the purpose of making the later patent ostensibly the generic one, so far as it relates to the contact device, such matter is antagonized by and is wholly inconsistent with some of the claims. Those claims in which the switching devices are not an element have no place in the patent, and would be in effect obliterated, unless they cover combinations between the suspended conductor and such a contact device as is described in the specification. In case of conflict, the claims, which are the final and definite expression of the patentee's intention, must control.

The operative parts of the contact device are described in identical language in each patent; and the language of the claims aptly describes these parts. While the function of the tension device is stated with more particularity in the earlier patent, the description does not contain a word or hint by which its characteristics can be differentiated from those of the tension device of the later patent. The additional matter is in effect a fuller statement of the advantages of the device.

As described in each specification the tension device is a spring which is held in its proper place by the weight. The spring alone, if fastened to the top of the car, would perform the function of restoring the arm to its normal central position; so would the weight "secured by a cord which passes downward through suitable grooves" (or through the roof of the car as shown in the drawings). The weight and spring together re-enforce one another and allow greater freedom of movement to the arm when arranged as described and shown in both patents. The device of necessity exerts a centralizing tendency upon the arm, and serves to maintain upward contact between the grooved wheel and the suspended conductor. Of course, if the claims of the earlier patent do not specify such a tension device as is described and claimed in the later, but specify one which embodies only a subordinate improvement upon it, the patents are not for the same invention. As was said by this court in Thomson-Houston Electric Company v. Elmira Company (71 Fed. Rep., 404): "An inventor, by describing an invention in a patent granted to him, does not necessarily preclude himself from patenting it subsequently. His omission to claim what he describes may operate as a disclaimer or an abandonment of the matter not claimed; but it has no such effect when it appears that the matter thus described but not claimed was the subject of a pending application in the Patent Office by him for another patent. The invention secured by a patent is that which is secured to the patentee by the claim. The claim, however, is to be read in the light of the description contained in the specification, and its literal terms may be enlarged or narrowed accordingly, but not to an extent inconsistent with their meaning. Identity of language in the claims of two patents does not necessarily import that the invention patented by each is identical, nor does a difference in the phraseology necessarily import that they are for different inventions. The test of identity is whether both, when properly construed in the light of the description, define essentially the same thing. When the claims of both cover and control essentially the same subject matter both are for the same invention and the later patent is void."

Inasmuch as the only tension device, or means for imparting upward pressure to a trolley arm described in the specification of the later patent is that which consists of a weight and spring as it is described in the earlier patent, the verbal differences in defining its functions in the several claims (of the two patents) are of no significance. The thing itself is the same in the claims of both patents.

If any importance is to be attached to these verbal differences, the earlier patent claims a tension device the chief function of which is to exert a normal centralizing tendency upon the arm, but which of necessity must maintain the upward pressure, while the later patent claims one of the chief functions of which is to maintain upward pressure, but must of necessity also exert the normal centralizing tendency. If there had been in the description anything by which could be ascertained which of the structural features exercises one function and which the other a different case would be presented. "The matter sought to be covered by the second patent is inseparably involved in the matter embraced in the former patent, and this, under the authorities, renders the second patent void." Miller vs. Mfg. Co. (151 U. S., 198).

Claim 13 of the patent in suit for the combination between the suspended conductor, the contact device, and the switching devices is identical in its phraseology with claim 6 of the earlier patent.

The later patent describes the switching devices of the earlier patent in all their essential features, except as to the subordinate improvements thereon and claim 13 must be construed as specifying the identical invention specified in claim 6 of the earlier patent. On the other hand, claim 15 of the earlier patent for the combination between the suspended conductor and the contact device is identical in phraseology with claim 9 of the patent in suit.

We are of the opinion that claim 15 of the earlier patent describes and embraces everything of substance which is covered by claim 7 of the patent in suit. Claim 15 specifies a combination, the elements of which are the car (implied necessarily, and needlessly mentioned), the suspended conductor and the contact device. The element termed "a contact carrying arm pivotally supported on the top of the car and provided at its outer end with a contact roller engaging the under side of the suspended conductor" exactly defines all the essential features of the contact device described in each specification, except the tension device. It must be hinged as well as pivoted, otherwise the tension device will be inopera-

tive to maintain upward pressure. The element termed "a weighted spring," is the complete tension device described in both specifications and which as described necessarily exercises the two-fold function of maintaining upward contact between the contact device and the suspended conductor and of maintaining the pivoted arm in its central or normal position. The "tension device" of claim 7 is the whole device described in that patent as the "weighted spring" of claim 15, is the whole device described in the earlier patent.

Claim 15, however, does not specify the combinations of claims 8, 12 and 16 of the patent in suit. The "tension spring" of those claims is not necessarily the "weighted spring" of claim 15.

We are also of the opinion that claim 33 of the earlier patent specifies essentially the same combinations embraced in claims 8, 12, and 16 of the patent in suit, and that the "spring or weight" of claim 33 is the same thing as the "tension spring" of claims 8, 12 and 16, the "weight"being only an alternative element. It would be a waste of time to dwell upon the verbal differences in these claims. The changes in phraseology import nothing of substance into their respective combinations. They describe the same things in different language and the draughtsman seems to have expended great ingenuity in cataloguing a group of synonyms.

The order granting the preliminary injunction is reversed with costs.

UNDERRUNNING TROLLEY AND SUSPENDED SWITCH.—THE DETROIT CITIZENS STREET RAILWAY CO. ENJOINED.

On July 15 Judge Swan, of the Sixth U. S. Circuit Court, at Detroit, granted a preliminary injunction restraining the Detroit Citizens Street Railway Company, of Detroit, from the use of the under-running trolley as covered by claims 2, 4, 6, 7, 8, 12 and 16 of the Van Depoele patent, No. 495,443, of April 11, 1893.

On the same day Judge Swan also granted a preliminary injunction against the same road prohibiting it from using the suspended switch as covered by the Van Depoele patent, No. 424,695, of April 1, 1890.

In both instances the Detroit road was given sixty days in which to substitute non-infringing apparatus.

A DECISION IN FAVOR OF THE CARBORUNDUM CO.

On July 27, Judge Buffington handed down a decision in favor of the Carborundum Company, in the case of Cowles vs. the Carborundum Company.

TROLLEY CURRENT INTERFERENCE WITH TELEGRAPH CIRCUITS.

The Postal Telegraph Company's allegation that its wires in Falmouth, Me., are being rendered nearly useless by the close proximity of tne trolley line of the Portland & Yarmouth electric railway, now in progress of construction, is the basis of the suit for a temporary injunction, which will come up for a hearing in the United States Court, July 31.

The electric railway company's reply to this allegation is to the effect that the Portland & Yarmouth Electric Railway Company has absolute right, under its charter, for the location of its wires and poles, and that the location has the indorsement of the municipal officers of Falmouth; that the Postal Telegraph Company never obtained any legal right to set poles within the town of Falmouth; that in the construction of its road the electric railway company has used all possible care to avoid injury to or interference with the poles or wires of the telegraph company, and any injury or annoyance that may have happened has been due solely to the neglect of the telegraph company to change the location of its poles, which it has had ample time to do since receiving notice to that effect.

CARBIDE OF IRON IN THE ELECTRIC FURNACE.

The results of some recent researches on the direct union of carbon and iron at a high temperature have been communicated by the author, M. Moissan, to the French Academy of Sciences. He states that when pure iron and carbon are melted together in an electric furnace and allowed to cool slowly, the metal is found to contain only a very small quantity of combined carbon, a gray pig iron being obtained that solidifies at 1,150 degr. Cent. By suddenly cooling in water iron saturated with carbon at 3,000 degr., the metal became crystalline in structure, and from it were separated brilliant crystals of carbide of iron.

TRADE NOTES & NOVELTIES

THE MASON TERRA COTTA CONDUITS.

GRADUALLY but surely electric light and railway companies are recognizing that not only safety but economy of operation is secured by placing their circuits underground.

The Potomac Terra Cotta Company, whose office is at No. 36 Corcoran Building, Washington, D. C., were the pioneers in the manufacture of terra cotta conduits for underground electric wires, having introduced them as early as

FIG. 1.—MASON ELECTRICAL SUBWAY CONDUIT.

1887. These conduits were made in several forms, principally rectangular, with two, four and six ducts, and were patented by Hon. John Lynch and Wilmot Lake, and generally known as the Lynch-Lake system. They were introduced and extensively used in Washington, Baltimore, Cleveland, Buffalo, Milwaukee, St. Paul, Chicago and elsewhere.

To obviate objections to the rectangular duct, Mr. George Mason, president of the Potomac Terra Cotta Company, devised what is now known as the "Mason" duct, which was first laid in October, 1896, in Washington, D. C., by the Postal Telegraph-Cable Company, and since then by the Chesapeake and Potomac Telephone Company, giving great satisfaction

FIG. 2.—MASON ELECTRICAL SUBWAY CONDUIT.

where used and eliciting universal commendation from experts in this line of work.

The accompanying engravings illustrate the Mason conduit, which is made in two and four-way ducts, the sections being connected by dowels of wood or other material and the center opening serving to carry a return wire.

Testimonial letters in the possession of the Potomac Terra Cotta Co. from the two companies above mentioned leave no doubt as to what conduit they will employ for extensions.

C & C APPARATUS IN THE WEST.

Sargent & Lundy, per Mr. M. J. Insull, Monadnock Building, Chicago, have issued the following notice to the trade: We take pleasure in informing you that we have associated ourselves with the C. & C. Electric Company, of New York, in the capacity of General Western Sales Agents, with our office at No. 13 to 15 Monadnock Building. We shall carry at this office a complete line of C. & C. apparatus from which shipments can be made promptly. In soliciting your business we would respectfully remind you that the C. & C. apparatus has been on the market for the past ten years; the universal success that it has met with is a guarantee of its satisfactory operation. The C. & C. Company, in addition to their well known types of bipolar machines, are now manufacturing a full line of multipolar generators for direct connection, or belted, and also a line of multipolar motors of the ironclad type. Kindly address all future inquiries to us at No. 13 to 15 Monadnock Building, Chicago, where they will receive immediate and careful attention.

EXTENDING USE OF CHLORIDE ACCUMULATORS.

It is a significent fact that the largest users of storage batteries are those who have given the subject of their manufacture and application the greatest amount of study. Four of the Edison Companies equipped with chloride accumulators have contracted for duplicate plants, i. e., New York, Brooklyn, Boston (3 installations) and Lawrence, Mass. About a year ago a battery of chloride accumulators was installed in the New York Custom House for the purpose of furnishing current for 12 hours per day when the dynamos were shut down. A contract has just been closed by the Electric Storage Battery Company for a second plant to be installed in the New York Custom House, to be used for maintaining the night lamps in the Sub-Treasury and the Assay Office.

Other contracts recently closed cover batteries of chloride accumulators for the San Francisco Gas & Electric Company, the Criminal Court Building, the Commercial Cable Building, the Queens Insurance Building, N. Y.; the State Mutual Assurance Company's new building, at Worcester, Mass.; and Messrs. Smith & Wesson, Springfield, Mass.

The installation of two batteries of large capacities has just been completed for the Consolidated Traction Company of Pittsburg, where they are used for regulation and maintaining the potential on their trolley lines, and the Barre & Montpelier, Vt., Railway Company has just contracted for a battery for regulation. The Postal Telegraph and Cable Company are installing chloride accumulators in their offices at Albuquerque, New Mexico, and El Paso, Texas.

Among the yachts which have been equipped with chloride accumulators this year, are: Embla, Alicia, Sapphire, Clermont, Pioneer, New Hiawatha, Marretta, Punjaub, Raynham, Althea, Satanella, etc.

THE VULCAN FOUNDRY CO., PROVIDENCE.

An event of unusual importance in the mechanical and engineering field at Providence, R. I., is the organization of the Vulcan Foundry Company, whose works are to be established at once at Pawtucket, in the vicinity known as Darlington. The company has a capital of $100,000, which was oversubscribed, and the directors are such well known men as Darius L. Goff, Gardiner C. Sims, and W. P. Dempsey. The officers are, Mr. Goff as president, and Mr. Sims as treasurer, and the numerous friends of the latter gentleman, in the electrical field, will hail gladly this evidence of his return to active business life. It is the intention to have one of the largest and most complete establishments of the kind in New England, and the foundry will start with a considerable custom already secured.

TRIUMPH ELECTRIC APPARATUS AT THE TENNESSEE CENTENNIAL.

A good deal of important work is now being done at the Tennessee Centennial by apparatus of the Triumph Electric Company, of Cincinnati, installed by Mr. John W. Chester, manager of the company's Nashville office.

Thus there has been furnished a 75 k. w., 500-volt generator in connection with a 14 x 14 Imperial engine, built by the Weston Engine Company, of Painted Post, N. Y. This plant furnishes power to all the motors in the different buildings on the grounds, and also power to operate the Giant See-Saw, the machinery for which was designed by Mr. Chester.

In addition to the above the company have a 15 k. w. multipolar, 110-volt generator as a special exhibit, driven by a Lane & Bodley engine, and a display of arc and incandescent lamps operated by the machine.

WALKER CO. IN CHICAGO.

Mr. George B. Foster, formerly of the electrical department of the World's Fair, has associated himself with J. Holt Gates & Co., 1323 and 1324 Marquette Building, Chicago, in the sale of Walker Company, Card Electric Company and Wagner Electric Manufacturing Company apparatus. Mr. Foster's varied experience in the electrical field renders him a very valuable man.

Mr. George W. Henry, formerly Western manager of the Steel Motor Company, has also associated himself with J. Holt Gates & Co. Mr. Henry is one of the pioneers in the electrical business, and has been very successful in the exploiting of electrical goods in the West.

Mr. F. B. Duncan, formerly foreman for Siemens & Halske Electric Company and later of the Northern Electric Company, of Madison, has likewise become associated with the Gates Company. His technical experience should bespeak for him a creditable career as a salesman.

A NEW WESTERN ELECTRIC SWITCH CATALOGUE.

The Western Electric Company, of Chicago, has just issued a very beautiful and complete catalogue of its E, EE and Q switches. The different-sized switches are described by numbers with their capacity in amperes, and all the dimensions of the switches are plainly given in tables, so that it is possible to drill switchboards before the switches are received, with the assurance that the switches will fit when they are placed in position. Further than this, a cut and catalogue number of every switch part is given, which facilitates the ordering of small parts at any future time. Special switches are made for 500 volts, and the Q switches, which represent the quick break type, are made in all sizes from 25 amperes up. There is also shown in the catalogue the latest design of the round type Ellicott voltmeter switch, the "V" changing switch and the switchboard spring jacks, plugs and cords, all of which are extremely high grade. A copy of this catalogue will be sent upon application.

IMPROVED ROENTGEN RAY APPARATUS.

In designing their new line of X-ray coils, Messrs. Queen & Co. have given careful attention to proportioning the different parts so as to get a very heavy and continuous secondary discharge with the smallest possible amount of wire. The distribution of the wire on the secondary was determined by measuring the discharge from single coils of a few turns of wire which were placed at intervals throughout the field of the primary. From the data obtained by these tests curves were plotted showing the proper distribution of wire for coils of all sizes. Similar methods were used to determine the size and number of turns of the primary and the amount of iron in the core.

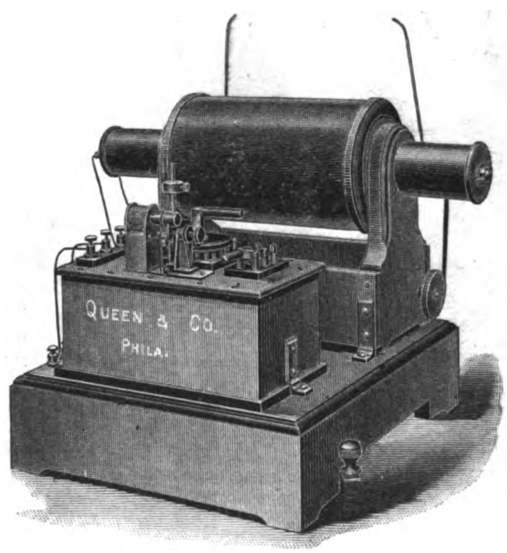


FIG. 1.—QUEEN & CO.'S IMPROVED X-RAY APPARATUS.

In the choice of insulating materials, and in assembling, the greatest possible care is used. Methods are employed which remove absolutely all air from the insulating material of the secondary. The spark points are adjusted by the hard rubber disc shown at the left of the base, which is so well insulated that the operator is in no danger of receiving a shock, even when the points are opened out to the full extent.

Two of the binding posts shown at the left in the illustration, are connected to the batteries, or lighting circuit, and the other two to the induction coil. The vibrator is operated by means of a small coil, shown in the cut, which is a shunt from the main circuit. An independent set of contacts makes and breaks the circuit through this coil; these are in front of the main contacts, and a switch near the binding post opens and closes the shunt circuit. The main circuit is controlled by the reversing switch shown at the right.

The movable platinum contact is carried on a small vertical spring behind the vibrator spring. When the contact is made the movement of the vibrator is not arrested, but continues to its full amplitude, thus allowing a long "make." The length of the "make" can be varied by screwing in or out the other platinum contact. The most important advantage of this arrangement is the suddenness of the "break," which is accomplished by the collar in the vibrator spring striking the movable contact while at full speed. In the new form as the break is made when the vibrator is at the middle of its swing,

the sudden blow with the entire momentum of the vibrator head is always sufficient to break the platinums apart, and once started the vibrator continues in motion until the current is turned off. The suddenness of the break makes it possible to use this form of vibrator on the 110-volt as well as battery circuits, it also adds very greatly to the efficiency of the induction coil with which it is used.

A rod screwed into the iron head carries a weight which may be moved up and down and clamped in any position with a setscrew. By this means the rate of vibration may be varied within wide limits.

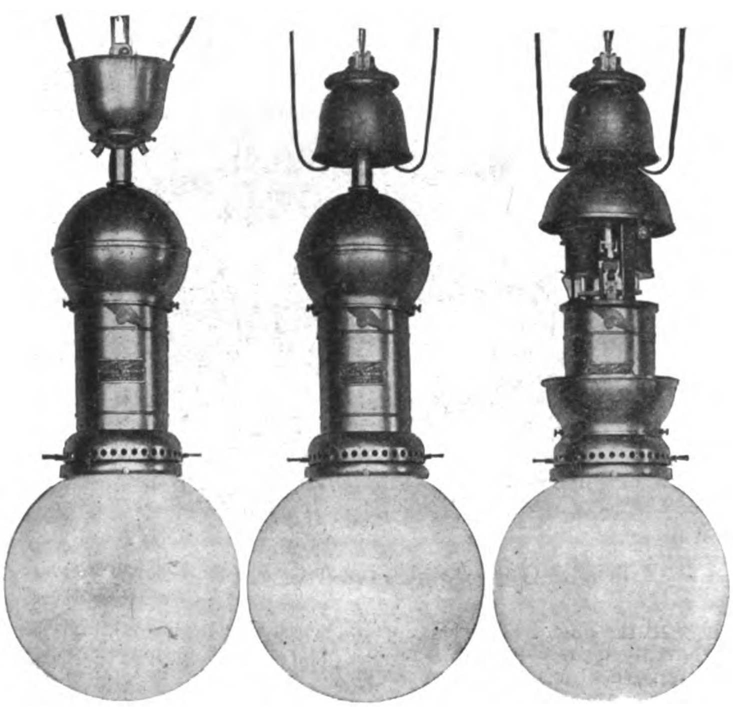
The outfits complete for X-ray work consist of a coil mounted on a base, with rheostat if used for 110-volt circuit, and with an adjustable condenser and independent vibrator mounted on the same base, as shown. In addition to this a number of tubes, suitable stand, fluoroscopes, etc., are included with each set.

NEW WESTERN ELECTRIC CO. 150-HOUR ENCLOSED ARC LAMP.

THE general design of the new 150-hour enclosed arc lamp of the Western Electric Company, is a marked departure from previous practice in this line.

By a special arrangement the rheostat and canopy containing the rheostat are adapted for either outdoor or indoor use, as shown in the illustration, slight change only in the arrangement of these parts being necessary to fit it for either use. This change can be made in a few minutes.

In the distribution of light great attention has been paid to all features giving a uniform distribution with freedom from shadows; also to giving the maximum illumination under such circumstances.



FIGS. 1, 2 AND 3.—NEW WESTERN ELECTRIC CO. 150-HOUR ENCLOSED ARC LAMP.

The large spherical globe is suspended entirely from the top and is without a lower opening; this, together with the arrangement of the inner globe and its means of support, form an ideal combination which is highly efficient in the matter of distributing the light from the arc over the area where it is most needed, and at the same time securing a uniform and pleasing illumination of the entire globe.

The regulating mechanism while of the simplest construction and requiring a minimum of energy to operate, is very effective and controls the voltage and current of the arc with such nicety that great steadiness and constancy in the light result. The lamps are equipped with either series or shunt controlled regulating mechanism as desired, so that they can be operated either singly on a constant potential of 110 volts, or a number in series upon higher potentials. Where a number are used in series an automatic cut-out is supplied, which, upon the consumption of the carbon in any one lamp of the series, will operate to extinguish the lamps and prevent injury.

For trimming, the globe is readily lowered, being held in the lower position by projecting arms attached to the side arm of the lamp, after which the inner globe, together with its lower carbon holder, can be removed for trimming, or be replaced by a fresh inner globe and lower holder already trimmed, the upper carbon having first been put in place.

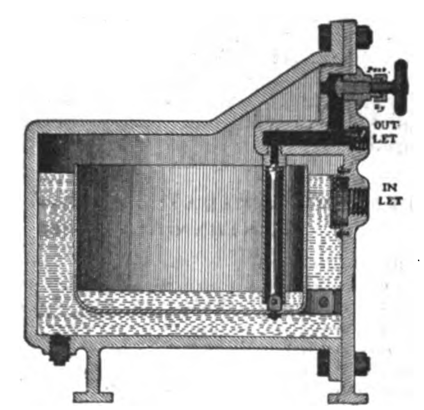
The carbons used are solid, ½ inch in diameter, 12 inches for the upper and 5 inches for the lower. After the lamp has burned 150 hours, there is still enough of the upper carbon left to be used for a lower in retrimming.

All lamps are equipped with spring-actuated switches, making a large, quick break which precludes the possibility of the formation of a persistent arc at the switch. These switches are also adapted to be operated by a simple pushing movement which may be communicated by a pole, by which they can be reached from the floor.

The lamps are finished in black, oxidized copper or any style the purchaser desires. The stem upon which the lamp is supported may be made any length to suit the height of the ceiling. In the accompanying engravings Figs. 1 and 2 show the lamp as arranged for indoor and outdoor use, respectively, and Fig. 3 shows it with the shell lowered, exposing the mechanism.

KIELEY & MUELLER'S STANDARD STEAM TRAP.

OF their many specialties in steam heating and regulating supplies no record is more satisfactory to Kieley & Mueller, 7 West Thirteenth street, New York, than that of their standard steam trap for automatically draining the condensation from all kinds of steam apparatus, independent of returning it to the boiler. While it is made to work under an incipient pressure of 100 pounds, it is used in the U. S. Navy ships at 250 pounas, and is in wide request for the high pressure plants of electric light stations, for the work of which it is peculiarly fitted. Wherever it is employed there is no further trouble with the water of condensation. The float, being an open one, prevents all danger of collapse; and, as it is hinged to the cover, its power is increased to three or four times that of many open floats used in drain traps. All the working parts are fastened to the cover, to which are also connected the inlet and outlet pipes. The result is that by simply unbolting the body of the trap and moving it back,



KIELEY STANDARD STEAM TRAP.

all the working parts can be seen in the position of action. As the inlet and outlet pipes are connected to the cover only, the trap can be taken apart and cleaned without disconnecting a single pipe. The pass-by, when open, allows the air and water to pass out of or through the trap independent of the opening controlled by the float. This arrangement, besides other advantages, obviates the otherwise necessary cost of a valve, pipe, fittings and labor in making a pass-by.

FIRE IN THE EXCELSIOR ELECTRIC CO.S FACTORY.

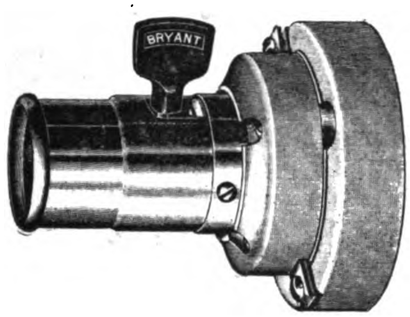
On July 27 a fire that was subdued in half an hour caused damage estimated at $15,000 in the Excelsior Electric Company's four-storied building fronting on Willoughby street, between Navy and Raymond streets, Brooklyn. The flames were confined to the top floor in the lamp department. The damage was mostly due to water, the machinery remaining untouched, so that the factory will be in running order within a few days. The factory, etc., is fully insured.

THE AMERICAN ELECTRICAL WORKS CLAMBAKE at Providence, R. I., is to take place on August 21, at the Pomham Club. Invitations are just out.

THE BRYANT FUSIBLE WALL SOCKET.

THE accompanying engraving represents the Bryant fusible wall socket, which the Bryant Electric Company, of Bridgeport, Conn., are now placing upon the market.

This device consists of the standard Bryant socket mounted on a "K.W." rosette, making a combination which will be found very useful as it is fusible and can be furnished in either the key or keyless Westinghouse or Thomson-Houston base. The



BRYANT FUSIBLE WALL SOCKET.

shell of the socket is held in place on the base by three bayonet joints, which makes it thoroughly rigid and solid, capable of supporting any weight of shade or lamp without sagging. The socket, being fitted to the rosette cap, can be used with any of the regular rosette bases, all caps being interchangeable.

BRISTOL'S NEW ATMOSPHERIC RANGE RECORDING THERMOMETER FOR CLOSED SPACES.

THE instrument here illustrated has been developed to meet a demand for a recording thermometer for atmospheric ranges of temperature that can be applied to air, gases or liquids in a closed pipe or room. Fig. 1 shows the complete instrument which consists of a Bristol recording pressure gauge, in which the helical tube is completely filled with expansible

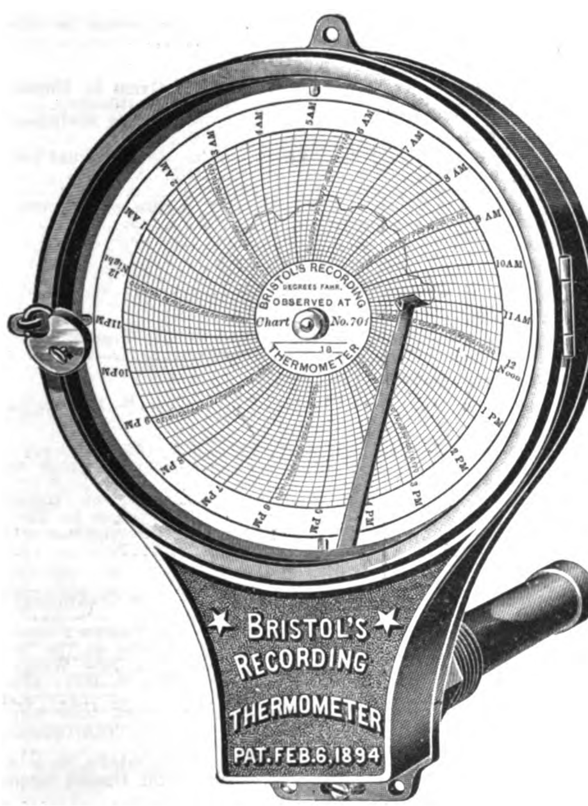


FIG. 1—BRISTOL RECORDING THERMOMETER.

liquid. This tube, which is sensitive to and is operated by changes of temperature, is inclosed in the cylinder projecting from the back of the case of the recorder, as shown in Fig. 1. This cylinder protecting the sensitive tube is furnished with a screw thread so that it may be conveniently located within a gas main, through the side of a tank, or through a partition of a room, as may be desired. Fig. 2 is an illustrative outline of one of the thermometers as applied to a large gas main; A, representing the protected sensitive tube; B, a cross-section of gas main, and C, the recording portion of the instrument.

It will be observed that the operative part of the thermometer is entirely protected from any action of the gases or liquids of the temperature which is being recorded, hence the

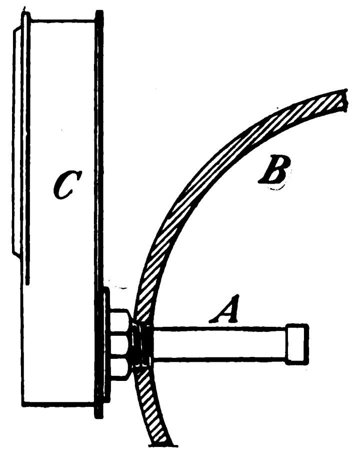

FIG. 2.

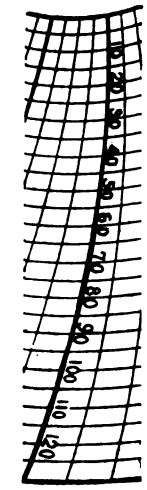

FIG. 3.

operation of the instrument is absolutely independent of the pressure or vacuum within the closed space.

Fig. 3 shows a specimen section of the chart of these thermometers for a range from 0 to 130 degs. F. Other ranges may be made by using weaker or stronger pressure gauge tubes. By varying the quantity of expansible liquid inclosed in the pressure tube, the lower end of the scale may be limited, and a very open scale provided at the normal degree of temperature. These instruments have been in successful operation for several months. They are being made and placed on the market by the Bristol Company, of Waterbury, Conn.

ADVERTISERS' HINTS

THE ELECTRIC SUPPLY CO., Madison, Wis., state that the month of June beats the record and that their goods and prices are all right.

THE PEOPLE'S ELECTRIC COMPANY, Madison, Wis., announce that they always have a full line of electrical supplies on hand.

THE WESTERN ELECTRIC COMPANY, Chicago and New York, illustrate and describe some types of their new 150-hour enclosed arc lamp. A description may also be found on a preceding page of this issue.

A. R. SPICER, Hoytville, Pa., advertises chestnut poles for trolley, electric light or telephone line construction. A card to Mr. Spicer will elicit full information.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., recommend the Westinghouse engine as a representative American product for which there is a steadily increasing demand in the markets of the world, and state that this recognition is solely on the basis of merit.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., call attention to their stock of electrical supplies as carefully selected and made up of only the best material.

THE ORIENT ELECTRICAL COMPANY, Youngstown, O., advertise incandescent lamps at 17 cents in barrel lots.

THE GENERAL ELECTRIC COMPANY advertise electric lighting generators, direct connected or belted, for the smallest isolated plant or the largest central station.

THE BRYANT ELECTRIC COMPANY, Bridgeport and Chicago, advertise fusible wall sockets.

THE AMERICAN MANUFACTURING COMPANY, 46 So. Water street, Cleveland, Ohio, are in the market with the Globe water motor fan and are prepared to make prompt shipments.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., call attention to their step-up and step-down transformers for long distance power transmission sys-

tems. They illustrate a group of six 600 k. w. 10,000 volts water-jacketed transformers as installed at Riverside, Cal., where they have proved high grade in every respect.

NEW YORK NOTES.

THE ELECTRIC ARC LIGHT COMPANY report a largely increasing business. They are receiving large orders with every mail for "Pioneer" long-hour enclosed arc lamps and have been compelled to add to their already large force in order to meet the demands. One of the largest of the numerous contracts that have been taken by this company is that of Messrs. Abraham & Strauss, retail dry goods merchants, of Brooklyn, N. Y., who are equipping their new establishment with "Pioneer" lamps. This building is an addition to their already large quarters, and, as soon as this installation is completed, the entire establishment will be equipped with "Pioneer" lamps. This is one of the largest contracts ever given for arc lamps.

THE NON-POLARIZING DRY BATTERY COMPANY, 347 West Broadway, New York, are booking good orders throughout the country for their O. K. dry battery, of which they are the manufacturers. The battery is showing exceptional results wherever it is used, which accounts for the large demand that is keeping the factory busy filling orders.

J. B. COLT & CO., 115-117 Nassau street, New York, are issuing a highly interesting catalogue in conjunction with their stereopticons, magic lanterns, etc., which they will be pleased to mail to any address upon application. It covers many other things besides lanterns, all of great interest and use for business and recreation.

CHARLES ARTHUR HAGUE, 39 Cortlandt street, New York, for a number of years has been the consulting and designing engineer for many plants throughout the country. His specialties are power plants for electric light and power stations; steam and electric pumping machinery; also special steel pipes for high pressures. Mr. Hague installs complete plants, guaranteeing them. Correspondence on the subject is solicited by him.

THEO. AUDEL & CO., book publishers, 63 Fifth avenue, New York City, are distributing a new and very neat catalogue of their books relating to the steam end of electricity. The catalogue, which is illustrated and printed in three colors, will gladly be sent to any address upon application.

EDISON MFG. CO., 110 East Twenty-third street New York, report a very satisfactory business in fan motors. The demand for these goods as well as other specialties of their make is keeping them unusually busy for this time of the year.

MR. C. H. FLORANDIN, of the C & C Electric Company, has safely returned from an extended trip abroad.

NEW ENGLAND NOTES

BOSTON MOTOR COMPANY, 17 Batterymarch street, Boston, have issued a neat catalogue of their experimental electrical supplies, showing their apparatus of all kinds, including batteries, motors, fans, X-ray outfits, telegraph keys, telephones, etc. The neat pamphlet is supplemented by electrical tables and formulæ.

A. & J. M. ANDERSON MANUFACTURING COMPANY, 289—293 A street, Boston, are making a good deal of a specialty of heavy switchboard work, and are issuing an illustrated price-list which embodies some of their admirable work in this direction. They have had a long and ripe experience in this field. They make their own copper castings, and all the details are carried out with the utmost care and precision. They are now placing on the market also the Hancock quick break switches, which have not been listed before, but are already very largely used. They will be glad to receive inquiries or send copies of the price list.

SHAWMUT FUSE WIRE COMPANY, 93 Federal street, Boston, Mass., have just issued a very neat, descriptive catalogue and price list of their tested fuse wire, tested fuse links, copper knife switches, etc. They will be pleased to mail catalogue to any address upon application.

THE O. C. WHITE COMPANY, Worcester, Mass., will soon put on the market several new specialties in brackets, etc. Their shop is running full time.

WESTERN NOTES

BULLOCK ELECTRIC MANUFACTURING COMPANY, of Cincinnati, are issuing a series of admirable bulletins, quarto size, profusely illustrated with fine cuts, devoted to their various classes of high class apparatus, in the line of generators and motors. One bulletin, for example, describes and illustrates the larger sizes intended for generators. Another is concerned with direct connected, slow speed motors for all makes of printing presses, and various types are shown and details are gone into. Another of the bulletins shows slow speed, direct connected motors for machine tools and other machinery. These pamphlets afford a striking idea of the immense strides now being made by motors in the conquest of the printing and factory fields.

The Electrical Engineer.

Vol. XXIV. AUGUST 5, 1897. No. 483.

THE 150,000 H. P. ST. LAWRENCE POWER DEVELOPMENT, NEAR MASSENA, N. Y.

INTRODUCTORY.

As already announced and briefly outlined in our columns an electric water-power development is to be carried out near Massena, N. Y., which exceeds in magnitude anything of the kind ever attempted, not excepting even the stupendous undertaking at Niagara. The entire working capital for carrying out the enterprise has been subscribed and contracts for all the work have been let, including fifteen electric generators of 5,000 h. p. each, with a like number of turbines of similar capacity.

THE PHYSICAL CONDITIONS.

Unique physical conditions have made possible the great development of power at Massena, with comparatively moderate outlay. The elements necessary for use of water-power are water in ample volume and fall practically available. With very great height of fall a moderate volume of water will produce the same amount of power, as much greater volume with much less height of fall. The volume must be constant to the extent required in order to secure continuous power. Many streams which have considerable falls have so great variations in the volume of flow as to render only very moderate developments of power practicable throughout the whole year. At Massena the volume of the St. Lawrence River is so great as to render certain constant continuous power to an extent far beyond anything that has ever been attempted.

The physical conditions are the St. Lawrence River carrying the enormous volume of water gathered from all the great American lakes, and having at Long Sault rapids a fall of over 50 feet; southerly from the southern shore of the St. Lawrence above these rapids there extends a comparatively level plateau of about three miles where it meets the valley of the Grass River, the water in which at this point is about 45 feet below that of the St. Lawrence above the rapids. (See map, Fig. 1. The Grass River has but a small volume of flow and enters the St. Lawrence below the rapids. A canal carrying the waters of the St. Lawrence from a point above the rapids to the valley of the Grass River will deliver that water upon turbine wheels with an absolute head of over 40 feet. This water, after actuating the turbines, will flow through the valley of the Grass River, and re-enter the St. Lawrence below the rapids. The head race of this power will thus be the St. Lawrence River and three miles of canal; the tail race will be the Grass River itself.

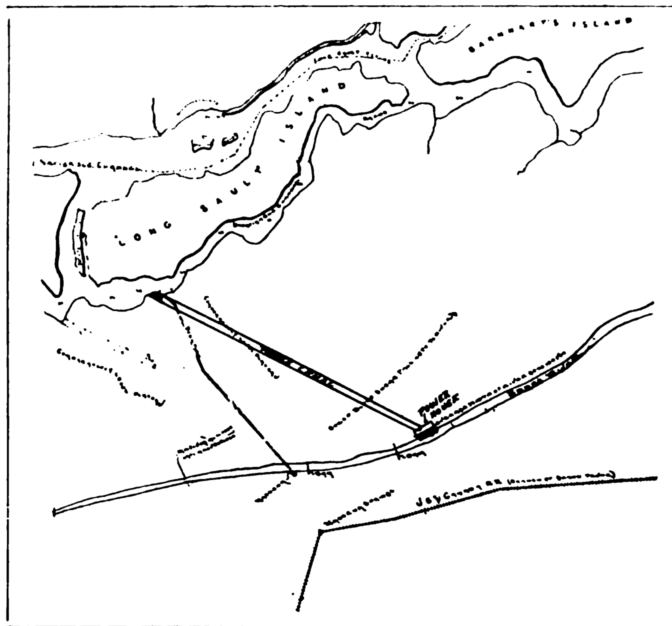

FIG. 1.—MAP OF MASSENA, N. Y., SHOWING LOCATION OF POWER HOUSE AND CANAL.

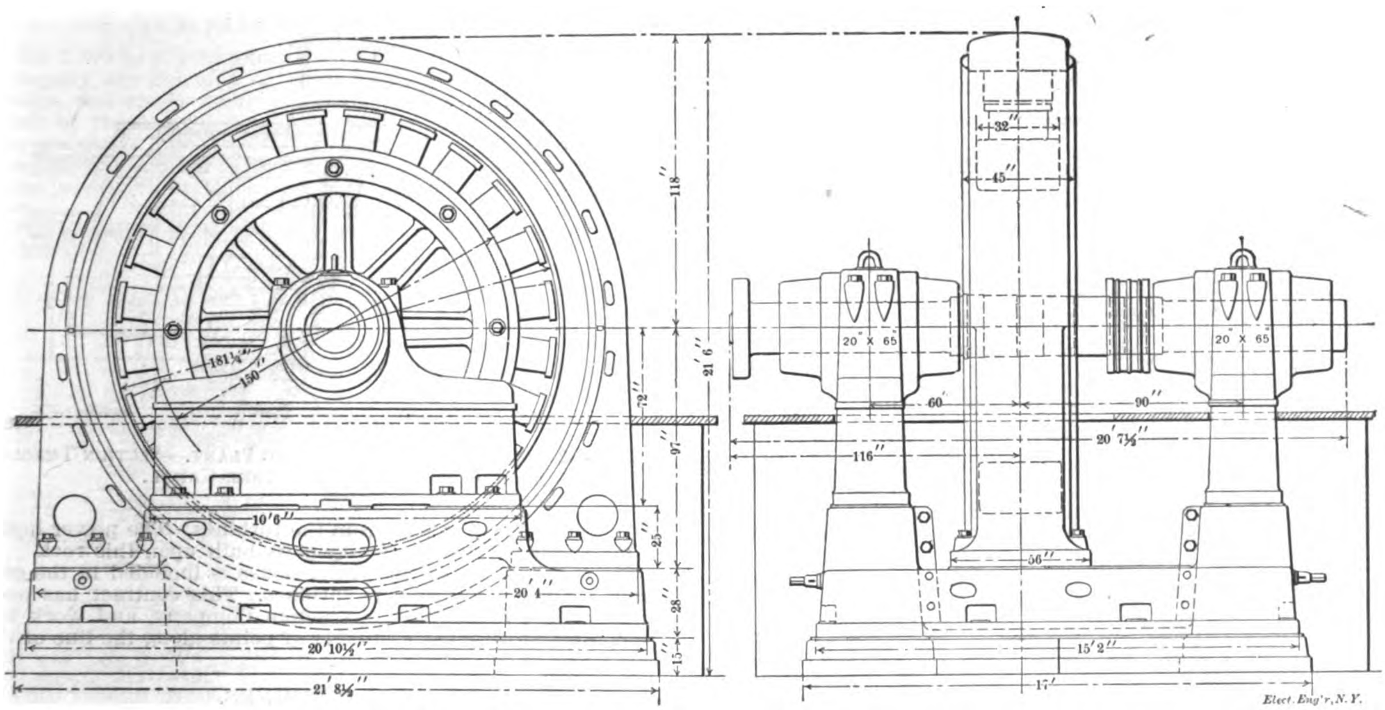

FIGS. 6 AND 7.—5,000 H. P. WESTINGHOUSE THREE-PHASE GENERATORS, ELECTRIC GENERATING PLANT, MASSENA, N. Y.

THE POWER CANAL.

After careful consideration of the commercial requirements that can be depended upon to utilize power at this point, the St. Lawrence Power Company has determined to construct a

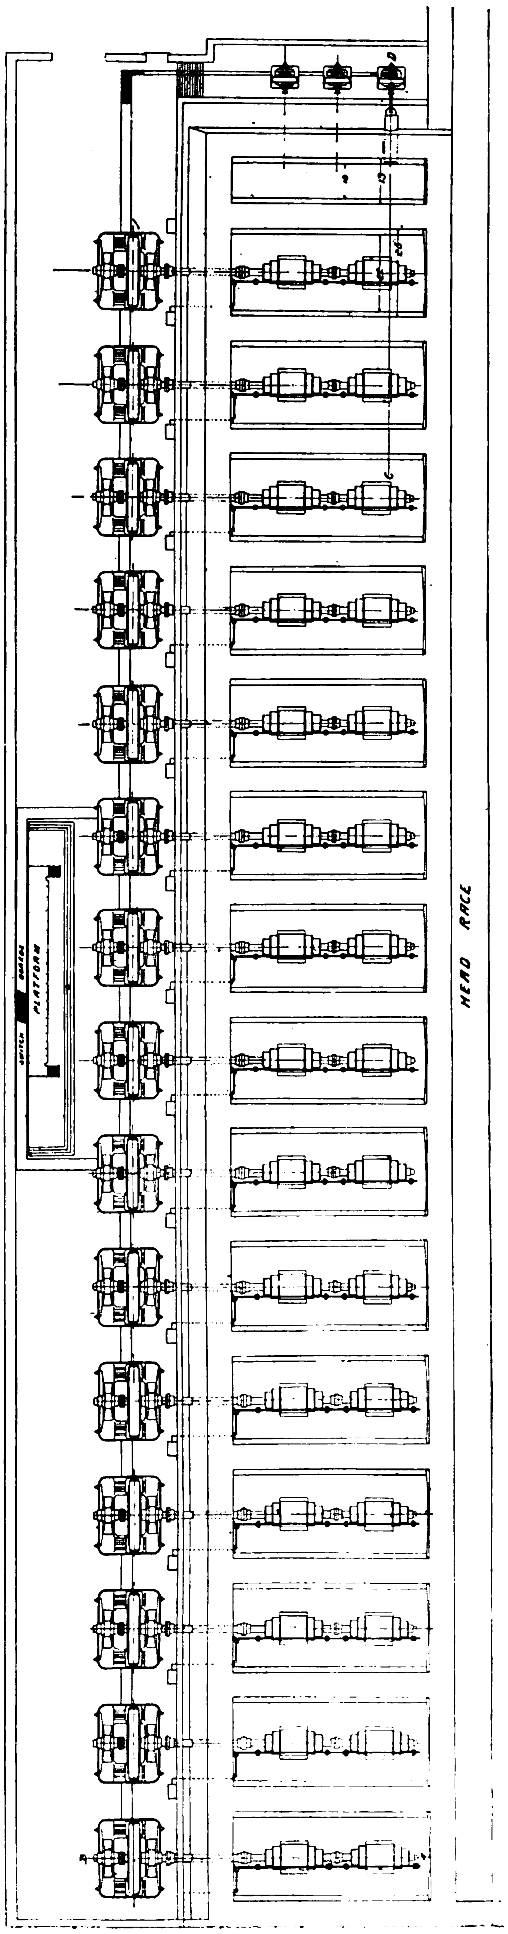

FIG. 2.—MASSENA ELECTRIC GENERATING PLANT.—PLAN OF POWER HOUSE, SHOWING ARRANGEMENT OF DYNAMOS AND TURBINES.

canal across this plateau of such size as to carry sufficient water to the valley of the Grass River to develop 150,000 h. p., and to at once build at the Grass River a power house and to furnish it with turbines and electric generators sufficient to develop, before the close of the year 1898, electric current to the extent of 75,000 h. p. There will be thus available for future use sufficient water to double this immediate output,

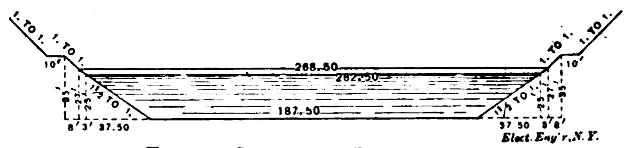

FIG. 4.—SECTION OF POWER CANAL.

and this can be used either for direct power in mills or other manufactures, or can be transformed into electricity.

The size of the canal for which contracts have been made and work upon which is now in progress, will be 225 feet wide and 25 feet deep; the sides will have slopes adapted to the material through which the canal passes. The line of the canal is nearly straight from the one river to the other. It is entirely in cutting, thus avoiding the dangers incident to embankments. The volume of material to be excavated is large, but as the excavation is entirely in earth the expense will be very moderate, as compared with its great volume. The Grass River flows upon a limestone formation, but the plateau between it and the St. Lawrence River is entirely alluvial, the material being sand, clay and gravel. The head of the canal at the St. Lawrence River is immediately below a slight promontory, which deflects to the opposite shore the ice and drift coming down from the upper river and lakes. The banks of the Grass River, where the canal approaches them, are over 40 feet in height.

THE POWER HOUSE.

The power house will be founded immediately upon the rock bed of the Grass River, and will receive the water for power from the canal which terminates in the elevated bank behind the power house. This power house will be between 500 and 600 feet long and 130 feet wide. The rock in the bed of the Grass River will be excavated so as to afford ample area for

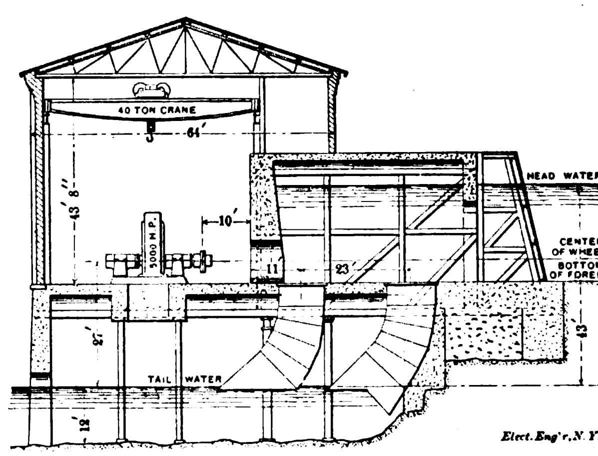

FIG. 3.—MASSENA ELECTRIC GENERATING PLANT.—SECTION THROUGH POWER HOUSE AND INTAKE CANAL.

the outflow of the water from the turbines. The power house will be founded upon masonry piers built upon this rock.

The construction of the power house is included in the contract for the canal and its turbines. This contract has been made with the Lehigh Construction Company, and work has been already begun at a number of points along the line of the canal and at the power house.

THE TURBINES.

The turbines to transform into moving power the weight of the column of water will be upon horizontal shafts. There will be two twin turbines upon each shaft, it requiring four turbines to produce the power and speed required. These turbines will develop upon each shaft 5,300 h. p. The turbines will be of the Victor type and contracts for their manufacture have been made with the Stillwell-Bierce & Smith-Vaile Company, of Dayton, Ohio.

The water from the canal enters the turbine chambers through suitable screens and after passing through the tur-

bines, is conveyed by separate passage for each set of turbines under the floor of the power house and out into the Grass River. (See Figs. 3, 5 and 8.)

The horizontal shaft of the turbines is extended through the wall of the turbine chamber, and into the power house, and still further extended in a direct line, becomes the shaft of the revolving parts of the great electric generators. Each unit of power developed is thus 5,300 h. p. transformed by the generators into 5,000 electric h. p. There will be in the portion of the power house now to be built fifteen of these systems or units of power, each of 5,000 h. p. capacity, thus developing in this power house 75,000 electrical h. p. Fig. 2 shows a plan of the power house arrangement.

The unit of 5.000 h. p. is the same as that adopted for the

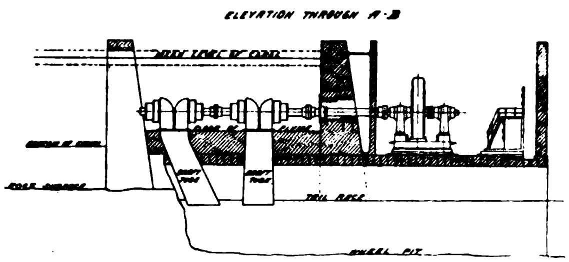

FIG. 5.—THE MASSENA ELECTRIC GENERATING PLANT.—ELEVATION THROUGH A-B.

works of the Cataract Construction Company at Niagara Falls. The construction of both the turbines and the generators is, however, quite different, the fall at the works of the St. Lawrence Company being less and the volume of water greater than at Niagara. Both the turbines and generators at Niagara are upon a vertical shaft of over 150 feet in length, while the turbines and generators at Massena are upon a horizontal shaft of about 80 feet in length.

The power house will be of good architectural design. It will rise to a height of about 60 feet above the water of the Grass River. It will have an electric crane traversing its whole length, and with lifting capacity of 85 tons. There will also be in the power house three separate turbines of smaller power, which will actuate the three exciter dynamos required for the operation of the larger generators; these are shown at the end of the building in the plan, Fig. 2.

THE ELECTRIC GENERATORS.

The 5,000 h. p. generators for the St. Lawrence Construction Company are not only of large size, but they involve a new design, and are in many ways different from other machines. Each of these great machines will weigh about 350,000 lbs., the weight of one piece being as great at 125,000 lbs. The machines will stand 22 feet high above the top of the foundations, and each machine will occupy a floor space of 22 x 18 feet.

The machines, illustrated in Figs. 6 and 7, have horizontal

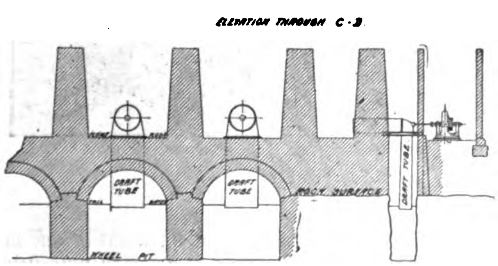

FIG. 8.—THE MASSENA ELECTRIC GENERATING PLANT.—ELEVATION THROUGH C-D.

shafts, which are in line and are directly connected with the shafts of the water wheels by which they are driven. The shaft carries a great ring of steel, which is similar to a large and heavy flywheel. This steel ring carries at its circumference twenty external projecting pole-pieces. The ring and the pole-pieces are of one solid casting of steel, the ring having an extreme diameter of 15 feet and a width of about 3 feet. It is supported from the shaft by a massive cast iron hub with ten radial arms. The steel for the ring is designed for very great strength; it revolves at a speed of nearly two miles a minute and the centrifugal force is such that each pound at the circumference tends to fly outward with a force of nearly 100 lbs. The speed of the machine is 180 revolutions per minute.

This great steel ring with the projecting poles revolves inside of a large stationary ring or cylinder, whose inner surface is made of plates of thin, soft steel on edge. These thin steel plates are held by a massive outer ring of cast iron, which has a total height of 22 feet. The thin steel plates which form the inside of the stationary part have slots in which are laid copper bars parallel with the shaft of the machine. These bars are insulated with mica, and they constitute the armature of the machine. The pole-pieces of the revolving field magnets are wound with copper strap coils, insulated with mica. The currents generated are three-phase, with 3,600 alternations per minute. The generators are now being built by the Westinghouse Company, at Pittsburg.

TRANSPORTATION FACILITIES.

The town of Massena is an ideal center for manufacturing purposes, with excellent railway facilities afforded by the New York Central and Grand Trunk lines, which meet at that point, while the Vermont Central is only six miles away, and it is understood that they contemplate building up to this new manufacturing center.

The head of the canal will be protected by gates and will be so arranged as to permit the passage into the canal of large lake vessels. Should it be deemed desirable in the future to erect a lock at the foot of the canal below the power house, this would give a passage for vessels around the Long Sault rapids of the St. Lawrence.

The St. Lawrence River is divided into two branches by the Long Sault island, which island is in the State of New York, the international boundary being in the center of the channel north of that island. The water of this power canal is thus taken entirely from that part of the St. Lawrence River within the boundaries of the State of New York. The volume of water passing down this channel is very great. The use of the water for this power does not in any way interfere with navigation, as it is returned to the St. Lawrence River directly below the rapids. Navigation on the Canadian side is provided for by the Cornwall canal, which extends from above the rapids to some distance below them, at the town of Cornwall, Canada.

FINANCIAL.

The St. Lawrence Power Company is a corporation organized under the laws of the State of New York, with a capital stock of $6,000,000. The officers of the company are: William C. Lane, president; S. H. Gardyne Stewart, vice-president; Carlton H. Reeve, secretary, and William C. Cox, treasurer. The company is owned jointly by the English syndicate, who are represented in this country by Messrs. Seward, Guthrie & Steele, New York, the well known firm of solicitors, and Messrs. Stewart & Co.

Bonds to the amount of $3,000,000 have been issued, with the United States Mortgage and Trust Company, of New York, and Messrs. Matheson & Co., the London bankers, as co-trustees. The bonds have all be taken in London by the syndicate above referred to.

Work has already commenced and will be finished by December, 1898. A large majority of this power has already been taken by a syndicate, who propose to use it principally for electro-chemical manufacturing purposes. The indications are that little, if any, of the power will be available for transmission, the demand for its sale being such as to justify the belief that it will all be used upon the premises.

In face of the adverse opinion existing in England in relation to the American securities, it is gratifying to know that Messrs. Stewart & Co. have succeeded in interesting London financiers in this most excellent enterprise, and is a long step in the direction of regaining that confidence which has been so unnecessarily lost.

The engineering work of the company is under the charge of John Bogart, of New York, and Messrs. Kincaid, Waller & Manville, of London, as consulting engineers.

"ABOVE ALL THINGS, PRACTICAL."

Mr. J. H. Winfield, of the Nova Scotia Telephone Company, Halifax, N. S., writes us: "I must congratulate you on the prevailing excellence of your magazine. It is above all things practical, which quality is the one most to be desired for the everyday engineer."

KEENE, N. Y.—The Keene Gas Light Company intends to put in an electric light and power plant transmitting current from Spragueville, and using probably the three-phase system. During the day the current will be used for power purposes.

MRS. ISABELLA FIELD JUDSON has presented to the National Museum at Washington a number of Field submarine cable relics and documents.

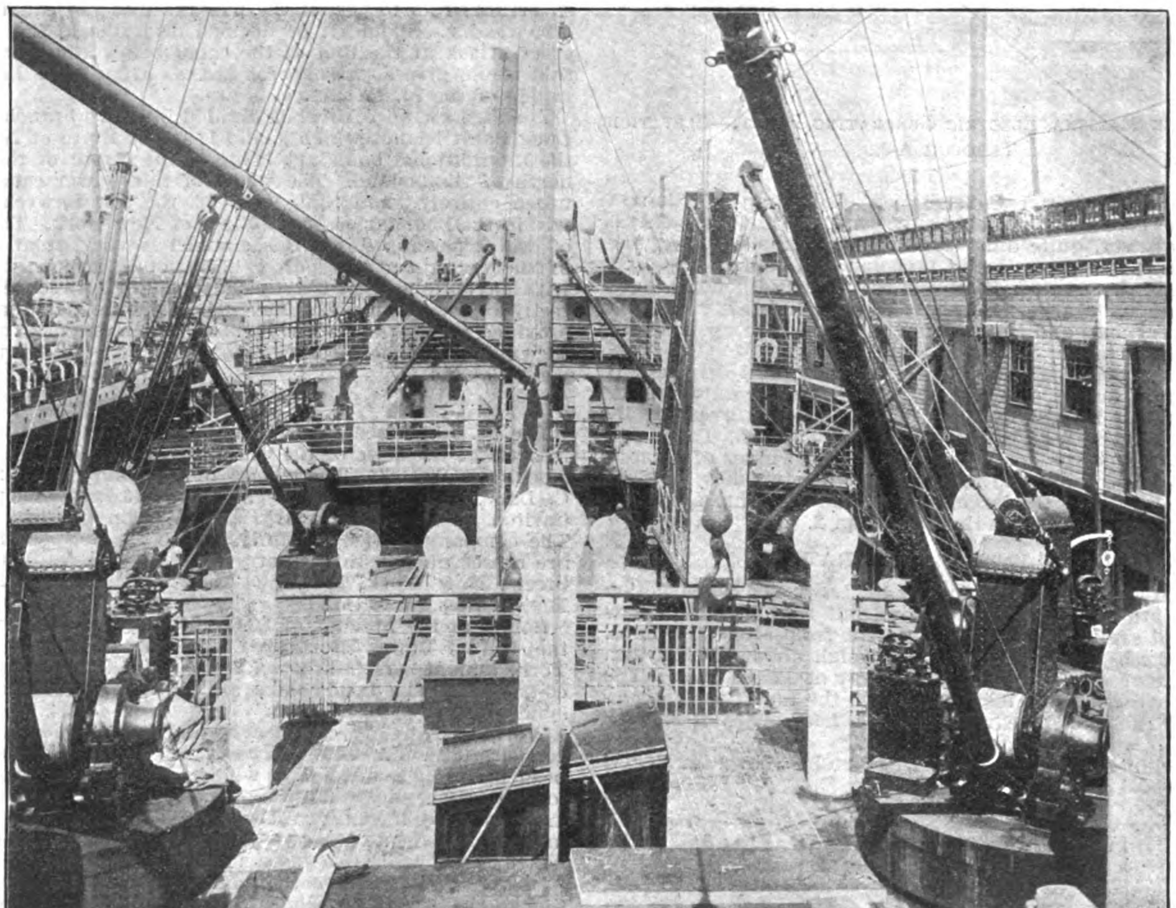
THE ELECTRIC CRANES ON BOARD THE S.S. "BREMEN."

THE steamship "Bremen" of the North German Lloyd Line, which recently made her first transatlantic trip, is, perhaps, more fully equipped electrically than any other vessel of the merchant marine in the world. Aside from the usual electric lighting plant, she has a very complete and most novel power plant, the successful operation of which is now fully conceded.

The first power installations on the steamers of the North German Lloyd were made by the Union Electricitäts Gesellschaft, of Berlin, the German ally of the General Electric Company, on the steamships "Darmstadt" and "Prince Heinrich." In these two cases the familiar and noisy donkey engine was superseded by electrically operated winches, and it was the successful operation of these that determined the North German Lloyd to extend the use of electricity to the "Bremen." In this case, however, in lieu of winches, a full equipment of electric cranes was installed. These cranes are sixteen in number, eight on the starboard side of the vessel and eight on the port side. Four of these have a capacity of 3,000 kilograms, or 6,614 lbs., and twelve of 1,500 kilograms, or 3,307 lbs., and have a total swing outboard of 20½ feet.

The power generating plant is located in the after portion of the engine room, and consists of four dynamos, each directly connected to its own engine. Two of these are placed on the starboard side and two on the port side. The dynamos have each a capacity of 75 kilowatts, or 100 h. p., and run at a speed of 210 revolutions per minute, delivering current at a pressure of 105 volts. The output of two dynamos is used for the cranes; one is used for the lighting of the ship, and the fourth dynamo is held in reserve in case of accident or other emergency. The engines are of the triple-expansion type and were built by Schichau, of Elbing, near Danzig.

The most notable feature of the electrical equipment is the cranes, the lighting installation conforming to the standard practice. In designing the cranes, the principal requirements specified and obtained were as follows: The load should be lifted smoothly; the resistance should be so arranged that the various speeds of the motors should be obtained without too sudden change; the control of the different motions should be instantaneous and positive, these motions to be effected in the smallest possible space; the cranes to be compact and contain the smallest possible number of parts; the controlling mechanism to be of the simplest to suit the class of operator likely to handle them, and the electrical apparatus to be absolutely protected against changes of weather, inroads of dust and sea water, and to be of such a nuture as to withstand rough handling. In addition, all conductors were to be carefully protected, and the last consideration, but, by no means, the least, on a passenger carrying steamer destined to be constantly loading and unloading, the operation of the cranes was to be noiseless. In conforming to these requirements, the Union Electricitäts Gesellschaft has produced what is the latest, and a very decided, innovation in a ship's equipment.



Electric Cranes on Board the North German Lloyd S.S. "Bremen."

The cranes, motor and controlling mechanism are mounted upon a circular iron platform, which revolves upon a pivot. This is turned by a motor of 7 h. p. running at 700 revolutions per minute, directly coupled to a worm gear, which, in turn, meshes in a gearing bolted to the deck. The loads are raised by a 25 h. p. series motor, running at a speed of 900 revolutions, and driving a special worm gear meshing into the gear of the drum. On this gear end of the drum shaft is fitted a winch head.

The controllers resemble a double street car controller about 2 feet high. They are fitted with magnetic blow-out. The contact cylinders are operated by a special mechanism actuated by a simple handle, the movements of which correspond to the movements of the load. Raising the handle raises the load; depressing the handle lowers the load, and movement of the crane to the right or left is obtained by corresponding movements at the lever. Raising and swinging movements can be effected simultaneously. So simple are these opera-

tions that the dullest stevedore can handle these cranes with ease. Motors and controllers are water-tight and dust-tight, but the cases of both can readily be opened when necessary. To give a more perfect control both motors are provided with to an extension of the motor shaft.

The difference between the large and small cranes lies in the hoisting speed. Practically both cranes are identical in electrical equipment, but the hoisting speed of the 3,000 kilogram crane at full load, 60 feet per minute, is only half that of the 1,500 kilogram crane at full load, 120 feet per minute. The movement of the jib of the cranes is 13 feet per second.

The most remarkable feature of the cranes, however, is the absolute noiselessness of their operation. During the visit paid by the writer of this to the vessel, the whole eight starboard cranes, four on the aft and four on the forward deck, were engaged in discharging cargo. Had the operation of hoisting and lowering not been witnessed, it would have been difficult to detect the fact, had it been necessary to depend upon the ear. It is this feature that will recommend the electrical crane to shipbuilders, especially those of passenger steamers in such trades as that of the Mediterranean, where loading and discharging is effected at every port, and great credit is due the North German Lloyd Steamship Company for first effecting this great innovation.

TELEPHONY AND TELEGRAPHY

THE STROWGER AUTOMATIC TELEPHONE EXCHANGE, AUGUSTA, GA.

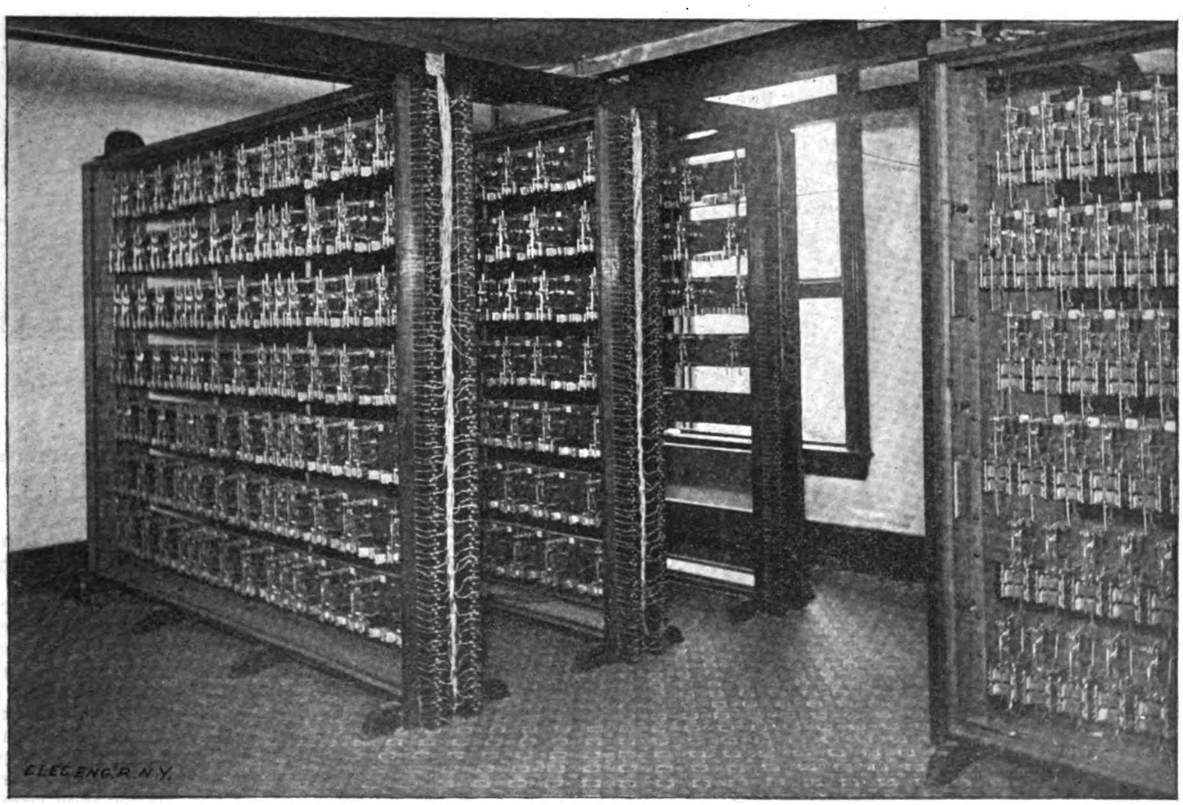
THE exchange of the Augusta Telephone and Electric Company, of Augusta, Ga., is probably one of the greatest novelties existing in the way of telephone exchanges, and is said to be the largest automatic telephone exchange in the world.

The offices of the company are on the fifth floor of the Jarvis-Conklin Building which is situated in the heart of the city. The construction of the lines was commenced February 15, last. Three hundred and fifty subscribers are now in operation and contracts are in hand for 250 more, and the lines are being pushed towards the outlying portions of the city. Hard drawn copper wire No. 14 B. & S. is used throughout the system, every subscriber has a complete metallic circuit, and all instruments are equipped with long distance transmitters.

A great deal of cable has been used in order to avoid chances for trouble and to cut down the expense of making cuts while running wires for new subscribers. The cables are the dry core paper cables with braid over lead covering, manufactured by the Standard Underground Cable Company. Trolley lines and lighting circuits have been avoided as much as possible in laying out the lines and the longest circuits are practically free from induction and other disturbances both night and day.

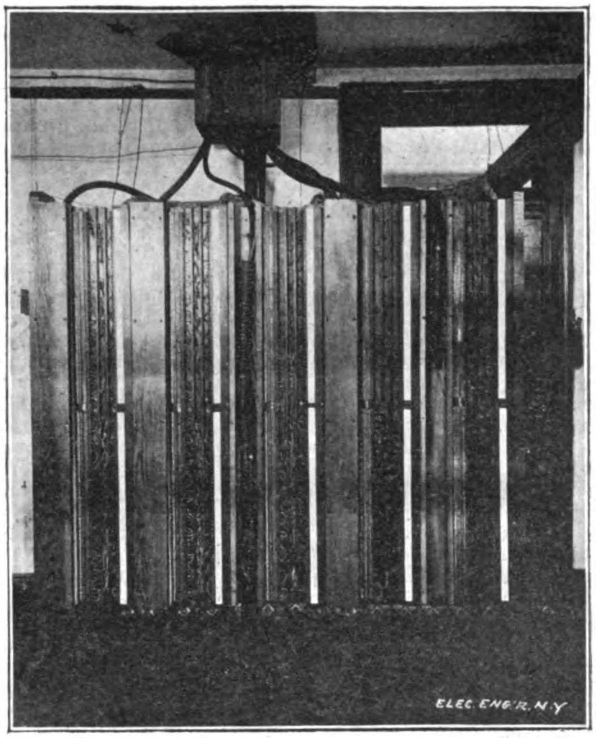
But the feature of the system which puts it in striking contrast with any system of the size is the switchboard. The telephone operator is done away with and the connections are made by the machines and system of the Strowger Automatic Telephone Exchange of Chicago. These connecting machines or switches are operated by means of electro-magnets which receive current from a storage battery at central through circuits manipulated by the subscribers at their telephones. One leg of the battery at central is a wire which extends over the entire system and taps into each subscriber's station. The other end of the battery connects through the electro-magnets of the switches to the bare wires of the subscriber's metallic circuit. Thus both ends of the central battery are furnished at the telephone, and by making contacts between the common feeder wire and the terminals of the bare wires which are called the "units" and "tens" lines, respectively, impulses are sent through the magnets of the machine at central.

These contacts are made and regulated by means of the numbered disk on the face of the telephone. This disk is pivoted at its center, and to call a certain number, the subscriber places his finger in the projections opposite the successive figures of the desired number, and turns the disk until his finger comes against the stop. That is, to call "386," the "3" would be pulled down to the stop and the disk allowed to return to its original position, then the "8" would be pulled down and the disk allowed to return, and lastly the "6" would be pulled down.



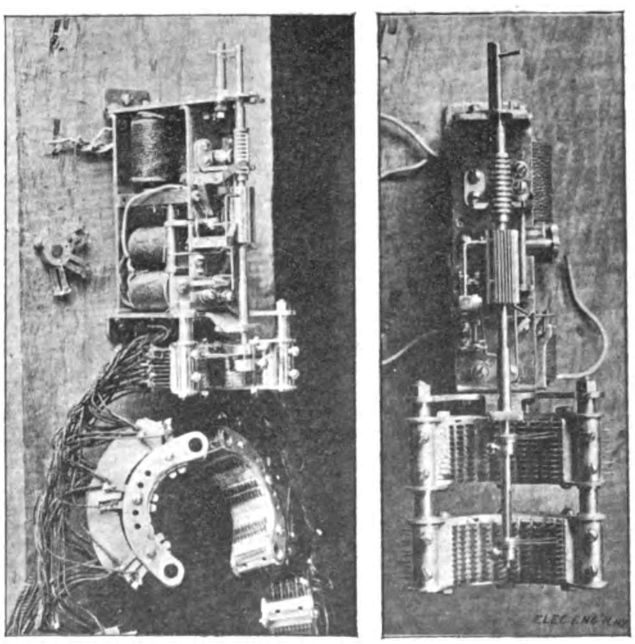
THE STROWGER AUTOMATIC TELEPHONE EXCHANGE, AUGUSTA, GA.—VIEW OF PRIMARY SWITCHBOARDS AND A PORTION OF A SECONDARY SWITCHBOARD. HEIGHT, 6 FT., LENGTH, 9 FT. 6 IN., DEPTH, 14 IN.

After each movement the disc is returned to normal position by means of a clock spring, and during the return movement it makes as many contacts as there are units in the number pulled down. That is, after the first movement in calling "386" the returning disk would make three contacts



DISTRIBUTING BOARD. CAPACITY, 1,000 WIRES. LENGTH, 7 FT., HEIGHT, 6 FT.

between the terminal of the unit line and the feeder terminal and thus send three impulses over the unit line to central. On the second movement of the disk eight impulses would be sent over the tens line to central and on the last movement six would be sent over the unit line again. This operation of



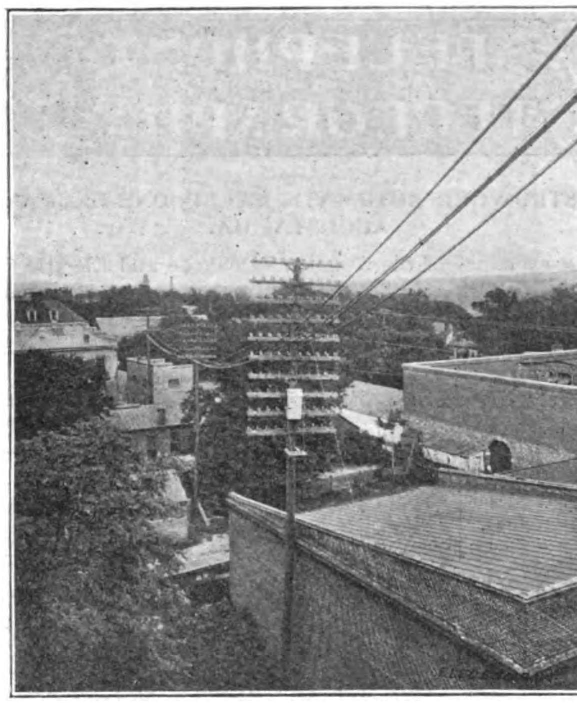
Single Primary Switch, Showing Banks and Wipers. *Single Secondary Switch.*

THE STROWGER AUTOMATIC TELEPHONE EXCHANGE, AUGUSTA, GA.

making the connection requires on the average from three to four seconds, and having finished it, the subscriber rings his bell and waits for the party called to answer. If his bell does not ring he knows that the party he wants is "busy" and he calls again in a few minutes.

The machines at the central office consist essentially of two sets of electro-magnets. One set is called the "unit" magnets and the other set is called the "tens" magnets, corresponding to the unit and tens lines just mentioned. Each set of magnets operates an armature which carries an arm with a pawl, which meshes with a ratchet hub on the shaft of the machine. One pawl moves the shaft in a longitudinal direction and the other revolves it. This shaft carries a set of spring wipers which make contact with the contact points shown at the bottom of the machine. These contact points are arranged in vertical and horizontal rows so that each movement of the shaft in a longitudinal direction carries the wipers up one row of contacts, and each movement of the shaft as it revolves carries the shaft around from one row to the next. So by properly regulating the impulses sent through the magnets by closing the circuits at the telephone the wipers can be set on any desired contact and thus connected to any desired "bank wire."

There are two sets of these machines or switches, one, called the primary switch and the other the secondary. A subscriber operates the same primary switch no matter what number he calls, but the secondary switch he operates depends



A TELEPHONE LINE BACK OF BUSINESS HOUSES FACING BROAD ST., AUGUSTA, GA.

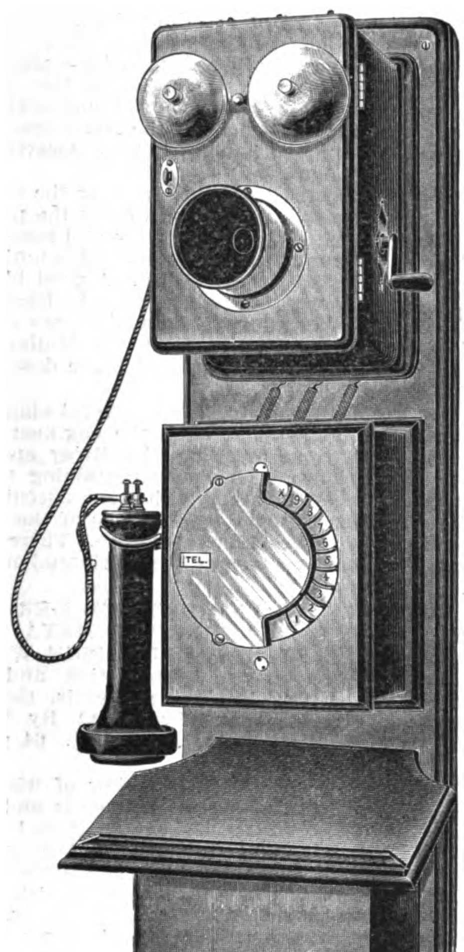
on the hundred he calls. He operates a certain secondary switch when he calls a number commencing with one hundred, another when he calls a number commencing with two hundred, and so on. The primary simply serves to select the secondary switch. So the primary is operated by the first set of impulses sent from the subscriber's station and the secondary by the last two sets.

The wiper contacts on the primary switches are arranged in three vertical double rows and the shaft carries three double wipers. The hidden ends of the contacts in one vertical row of one pair of rows are connected to the unit magnets in the respective secondary switches. The contacts of the other row of the same pair are soldered together and connected to the unit line. Hence when the double wiper comes on any pair of these contacts it connects the unit line through to the unit magnet of the secondary switch. Similarly a second pair of contact rows are used to make the connections from the tens line through to the tens magnets of the secondary switch, while the third pair of contact points are used in making the connections for the private attachment, which is explained later.

For example, if "386" is called, the first three impulses carry the wipers up opposite the third horizontal row of contacts. The first impulse of the "8" turns them in on the contacts, thus connecting the lines through to the three hundred secondary switch and at the same time cutting out the mag-

nets of the primary switch. The remaining seven contacts of the "8" are thus made to send current to the secondary switch, whose shaft carries two wipers. These wipers are carried up opposite the seventh row on the upper and lower banks respectively. Then the six impulses turn them about to the sixth contact in the horizontal row. This places the upper wiper on contact "86" in the three hundred bank and completes the connection. The hidden end of each contact in the section is connected to an individual line whose number commences with "3."

The lower wiper is called the private wiper. If a second subscriber calls the same number while the first subscriber is still talking, when his private wiper comes on the same contact as that of subscriber No. 1, a circuit is hereby closed through a third magnet on the switch thus operating an armature which opens the last subscriber's line and prevents him from cutting in on the conversation already in progress. After a subscriber is through talking he simply hangs up his receiver and as the hook comes down contacts are made between the battery feeder and the unit and tens lines in such a way that the magnets at central operating on their armatures release the shafts of each machine and a spring returns each shaft to its normal position ready for another call.



THE STROWGER TELEPHONE TRANSMITTER.

A storage battery of 48 cells of 40 ampere-hour capacity operates the switches. The battery is re-charged in the evening, but the re-charging does not interfere with the operation of the exchange.

One man attends to everything about the central office during the day, and after ten o'clock at night and on Sundays the exchange is locked up. All lines are tested every morning for breaks, crosses and grounds by using a few cells of the central battery for a test battery. The tests only require a few moments and do not annoy the subscribers in any way. All telephones are inspected on an average, once a month.

The points about the system which are especially worthy of notice are: the great speed and simplicity with which connections are made, the small number of wrong connections, the opportunity to ring a subscriber's bell until he is compelled to answer the call, the absence of cross talk and induction from the lines, the absolute privacy of each conversation and the chance to do business over the wires without interference from operators or other subscribers.

Such a system as that put in at Augusta is more costly than most of the opposition exchanges have been, but the officers of the company realize that to compete successfully first class service must be given and that such service cannot be maintained at a small cost without using the best of material and good instruments. Good material and good workmanship are as quickly appreciated by both patrons and stockholders of a telephone system as in any other business enterprise. And a pleased patron is always a company's best advertisement—a very old but a very truthful saying.

The exchange is under the able management of Mr. P. D. Langdon, with Mr. Lee Campbell, superintendent.

THE BABCOCK MARINER'S ELECTRIC SOUNDER.

THE Lloyds in estimating the causes from which all kinds of ocean craft have met their fate in the past 15 years assign 44 per cent. of such causes to strandings, because of fog, darkness, etc., in unknown depths of water, but at a time, of course, when the craft's officers imagined that their vessel had plenty of water under its keel. To place in the hands of mariners an apparatus which will enable them to ascertain with ease and certainty the depth of water under their vessels, Dr. J. F. Babcock, of Bangor, Me., has recently devised the electric sounding outfit illustrated in the engraving, Fig. 1; the sounder is shown in section in Fig. 2.

An iron ball, with a rod or standard attached, is suspended at the bottom of a cylinder by the rod passing through a hole in the bottom of the cylinder, which is rendered water tight by a rubber cap that moves with the rod as it passes in and out, the rod connecting with a spiral spring inside the cylinder.

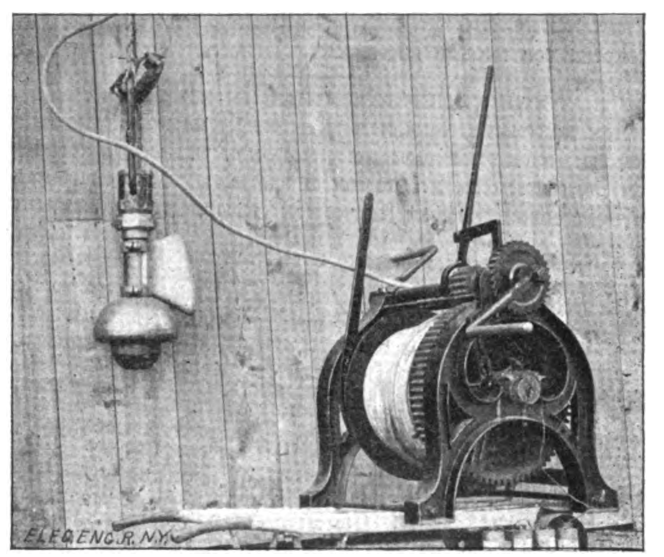


FIG. 1.—THE BABCOCK ELECTRIC SOUNDING OUTFIT.

When the ball is suspended, there is a space of about one-sixteenth of an inch between the upper end of the rod and the ends of the conducting wires, and, when the ball and rod is pushed up through that space, the ends of the wires are connected, completing an electric circuit. When the cylinder is towed at the end of the cable, from the bow of the vessel, at any given depth of water, the ball strikes the bottom when the water has become that depth shoaled, and is raised to make the connection of the wires in the suspending cable, which sounds an alarm on board the vessel. The winch shown in Fig. 1 carries 300 feet of cable. The latter, which was made by the Simplex Electric Company, is sufficiently strong to bear a strain of 7 tons.

The fan or rudder device seen on the sounder is designed to overcome any rotation or twisting of the cable when dragging through the water. The electric action of the sounder is so sensitive that no matter what the position of the sounder is when it touches the bottom, or when, for an instant the strain is relaxed upon the cable, the connecting bells will ring.

The winch carries a commutator at the axle point at the side exposed in the engraving, and the corresponding point at the other end of the axle carries a cyclometer showing the

number of fathoms of cable that have been paid out. The winch crank can be turned either way without disturbing the current.

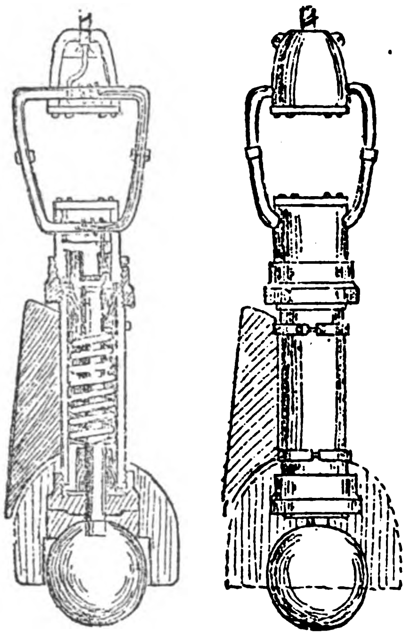

FIG. 2.—THE BABCOCK ELECTRIC SOUNDER.

It goes without saying the apparatus is also particularly adapted for marine surveys.

THE TELEPHONE WAR IN ST. LOUIS.

"Six hundred thousand dollars for undergrounding; $1,000,000 for general extension of business." That is the way General Manager Geo. F. Durant, of the Bell Telephone Company of Missouri, puts the increase in the capital stock of that company from $400,000 to $2,000,000. Mr. Durant was asked if the increase did not have something to do with the prospective fight with the Kinloch Telephone Company.

He smiled contemptuously and said: "The Kinloch Company's affairs have not influenced us in the slightest degree. We have talked of this increase of capital for over two years. We have needed money for the general extension of our business and of the $1,600,000 increase $1,000,000 is for the purpose mentioned. The undergrounding will cost, with its incidental changes in wires, switchboards, new instruments, etc., about $600,000. That is the whole thing concisely."

Nevertheless there are those who look upon the million dollar "general extension" fund as being much like the business end of a bee—always ready. One gentleman, who would not talk for publication if his name were given, said to a "Star" reporter that the Bell company was getting into a position to meet all comers; that the $1,000,000 was for general business, but that general business was of such a character as would make the situation interesting. This gentleman, who is in a position to speak by the card, said that if it became necessary the Bell company would put up such a fight as has never before been seen in a telephone war. The Bell company would not show its hand until the real fight was on—that is, until the new company was prepared to give service, of whatever kind it may have. Then the assault at arms would be a fierce one, it being intimated that a killing cut in rates would be the method adopted.

The situation was thus described: "It will be necessary for the Bell company to make an example of the Kinloch company to prevent wars in other towns. Wars are expensive, you know, and a crushing defeat here is the only thing that would prevent speculators in other towns from starting rival exchanges with the purpose of effecting a sell-out at a round profit. For this reason the Bell company will make bitter war on the Kinloch company when the time comes, for it must be settled now which is to be supreme in St. Louis, else the Bell company will be made a mark in every town in the country.

"It would be cheaper to spend millions even here to crush a rival than to be drained dry in every town in the country. which would be the case should it be demonstrated that headway can be made here with a rival exchange."—St. Louis Star Sayings.

LITERATURE

THE APPLICATION OF ELECTRICITY TO RAILWAY WORKING.—By W. E. Langdon. New York: Spon & Chamberlain. 1897. 331 pp. 5½ x 8½ in. 142 illustrations. Cloth. Price, $5.

The first impression gained from a glance at the title of this work might lead the average American reader to infer it refers to the operation of electric railways, but a glance within the covers of the book would soon disabuse him of that opinion. As a matter of fact the work is devoted to the description of methods of electrical control of railway trains, including signaling, switching, etc., with brief reference to the lighting of trains and yards.

In carrying out his plans the author gives complete details, first, of the method of erection of a railway telegraph line, with very complete details both illustrative and descriptive of methods of construction. Some of the photographs of English railway lines which we notice in the work are in strong contrast to the same class of work met with on American railways, and for the benefit of the latter one might wish that the work were in the hands of every American railway telegraph superintendent.

In the chapters devoted to block signaling the author takes up the various systems in use in England at the present time, among them the block signaling systems of Preece, Tyer and others. Among the automatic systems we also notice the Hall system, employed in the United States. A good idea of what has been done in the way of train lighting in England can be gathered from the description of the equipments employed on the London, Brighton & South Coast, the Midland and the Great Northern roads in England, which are described in detail.

The author has done well to devote several chapters to the subject of administration, including the engineering branch, the duties of the various officers and railway employés, etc. We also notice various check sheets pertaining to the work of the train dispatcher, together with other useful tables and blanks. Taken altogether, the work is one of the best of this kind which has yet come under our notice. There is much in it that American railway telegraph superintendents will find of profit.

ENTWICKLUNG, BAU UND BETRIEB DER ELEKTRISCHEN OFEN ZUR GEWINNUNG VON METALLEN, CARBIDEN UND ANDEREN METALLURGISCH WICHTIGEN PRODUKTEN.—(Development, Construction and Operation of Electric Furnaces for Producing Metals, Carbides and Other Metallurgically Important Products.) By W. Bochers. Halle a. S. Wilhelm Knapp, 1897. 5½ x 8¼. 64 pp. Paper. Price, $1.

This little volume is an excellent review of what has been accomplished in the way of producing metals and other metallurgical products by means of heat generated electrically. The author divides his subject under two headings, describing under the first furnaces depending upon the heat generated by the resistance of conductors, and, second, by the heat obtained from the electric arc. The illustrations, which are throughout very clear, show the types of nearly all furnaces which have thus far found employment in practice or have been suggested. We also notice several valuable practical tables relative to the density of current in furnaces employing carbon rods, both as heat producing resistances and as the electrodes for the arc.

INTRODUZIONE ALLO STUDIO DELLE APPLICAZIONI ELETTRICHE.—(Introduction to the Study of Electrical Applications.) By M. Ascoli. Published by Elettricista. Rome, 1897. 312 pp. 6½ x 9½. 123 illustrations. Paper. Price, $1.75.

This work is in the nature of a text-book, designed to present to the student the principal theories on which electrical work of to-day is based. The author presupposes the student to be fairly well equipped mathematically.

DIE ELEKTRICITAET UND IHRE ANWENDUNGEN.—(Electricity and Its Application.) By Dr. L. Graetz. Stuttgart; J. Engelhorn, 1897. 556 pp. 6 x 9 in. 365 illustrations. Paper. Price, $2.80.

This is an excellent work, giving in simple language descriptions of modern electrical apparatus employed in electrical transmission of intelligence, power, electrical illumination, etc., and the theory upon which it is based. While not entering into abstruse theories the information given is always strictly accurate, and it is one of the best popular technical works that has come under our notice.

LETTERS TO THE EDITOR

THIRD RAIL EXPERIENCE.

As a constant reader of The Electrical Engineer, I would like to ask about the "third-rail" system as used by the N. Y., N. H. & H. R. R. Co. On reading your issue of June 2, and, in fact, several previous issues, I have formed an opinion of the "third rail" used by the above company, as being a subject that will bear some considerable discussion.

I think that President Clark deserves a great deal of praise; he is apparently "up to date," but it seems to me that he has not been well advised in some of his electrical ventures. Why is it that we never hear of any of the bad things in connection with the "live rail"? In the description of this rail in the issue of June 9, I am sure that the writer is greatly mistaken in many of his statements.

He says that handling 600 volts is attended with some risks and goes on to say that a large conductor makes it quite safe. It seems to me that, considering the position of this rail, 600 is not a low voltage and putting the steel rail on equal footing with copper, it is not an extra large conductor. The idea that a large conductor is safer to handle than a small one seems to me to be something "new." Will the chief electrician of the company explain this point, or is it beyond explanation? He speaks of years' experience with the third rail; if I am informed correctly the third rail has been in service but one summer and has not been tested during the winter.

I can find no record of a cloud burst in the weather bureau's files, although it may have escaped their notice. Then, again, he says that short circuiting is unknown in the years' (?) experience at Nantasket. Is this a fact? If it is, what was the cause of the burning up of so many circuit breakers last season? I think if H. K.L. will take the troble to get reliable information on this subject, he will find that it is just the opposite to his statements. In fact, it was almost a daily occurrence to replace one or more circuit breakers used on the third rail. Also about workingmen getting "shocked," it may be a nice thing to call it "muscular contraction," but it was a decidedly different thing to the victim.

INNOMINATO.

THE DISCUSSION OF PLAIN IRON CONDUITS.

Will you permit a casual but interested reader a few words in criticism of "Jim Crow's" recent article upon the subject of Plain Iron Conduits.

It appears to me that his attack upon the consistency of those who advocate the use of uninsulated conduits in lieu of the insulated article is not only uncalled for by the facts presented, but is not justified by his argument. In order to make a prima facie case against such advocates he is compelled to assume that the men who have of recent years "put forth an incalculable amount of energy in creating and codifying rules which have the one word 'Insulation' as their sole foundation," have themselves correctly apprehended the right lines of "Safe Construction," and that all who hold or think that insulation is not a prime factor are necessarily in error. From these premises your correspondent is, of course, easily able to indict those who now advocate the use of uninsulated conduits as guilty of "inconsistency" and of "taking a long step backward"—particularly when, as in the case he cites, he is able to lay to their charge the absurdity of interrupting the continuity of the conducting envelope by the occasional insertion of an insulating joint. Your correspondent would appear to be incapable of making due allowance for the befogging influence of habit—else he would not condemn the advocacy of a revolutionary reform because, forsooth, a clear perception of its full scope is not immediately had by its advocates. Such apparent inconsistencies are the inevitable concomitants of all reforms, a clear recognition of the inutility of certain inherited accessories is seldom had except through long experience.

Let us. therefore, cease cavilling and inquire simply as to which is the safer conduit for electric conductors, insulated or uninsulated. This is, after all, the sum of the matter in so far as it comes within the purview of the underwriters.

In the argument for uninsulated conduits there must necessarily be assumed an insulation upon the conductors themselves, sufficient to insure a reliable and durable service. The only question involved in this assumption is as to whether the wire insulations of commerce can and do afford the requisite reliability. The contention, of course, is that they do. If this contention is well founded, then no auxiliary insulation is essential for this specific purpose and the whole subject is reduced to a question of relative safety.

In promulgating the decree that conduits are merely wire raceways and must not be depended upon for insulation, and in the logical supplementing of such decree by the further one permitting the use of uninsulated conduits, the underwriters have apparently concluded that the insulation of a conduit adds nothing to its efficacy as a safeguard against fire.

Upon this crucial point I observe that your correspondent does not touch. He simply assumes that insulation being admittedly a necessity somewhere, its multiplication becomes an added safeguard and ergo, any subtraction is inconsistent, illogical and foolish. Is this a justifiable assumption? That is what the inexpert would like to know. If it is not, then your correspondent is wasting his powder by firing in the air. If it is, then those to whom is entrusted the important duty of regulating the use of electricity have been culpably careless in relaxing their vigilance, and may very properly be held responsible in the event of serious results.

Perhaps, Mr. Editor, "Jim Crow" may be willing to throw some light upon this important element of the interesting and valuable discussion. "DOE BIRD."

New York City, July 30, 1897.

THE FUTURE OF THE FAN MOTOR.

The editorial in the July 8 issue of The Engineer on fan motor work has interested us very much. We agree with you on nearly all of the points which you make especially with reference to the advantages of using them in hotels and similar places. The fan motor has evidently passed the stage of being a luxury entirely, and is now being used as a necessity, and, of course, when the general public becomes acquainted with their many merits, and the fact that even in the hottest weather, a good night's rest can be obtained by their use, we believe they will become as general as the use of ice or fly screens.

We have been operating our factory both night and day for the past two or three months upon fan motors, and have been unable to keep up with the demand, and we believe this great demand is largely caused by the fact that people are buying them for home use. Instead of its being a rarity for a person to have a fan motor in his residence, it has now become a regular thing for a person to order two or three at a time for this purpose, as it is found that with fan motors at the present prices the labor of carrying them from room to room is burdensome, and it is much easier to have one in each room where they expect to use them. The fan motor, like everything else, is being improved each year both in cheapness and in quality, and we are inclined to think that in the course of a few years, we will have fan motors which are perfectly noiseless and which can be operated with perfect satisfaction in the quietest bedroom or sick room.

C. R. MESTON,
Secretary The Emerson Electric Mfg. Co.
St. Louis, Mo.

THE CONDITION OF BUSINESS FROM A PRACTICAL STANDPOINT.

It may be of interest to the readers of The Electrical Engineer to consider for a moment the general condition of the electrical business to-day. Over-production combined with over-zealous competition has placed the manufacturers in the electrical line in such a position that they are selling their goods without a profit. This condition exists in all branches of the line, not excluding the electrical contractors, who have been and are now accepting contracts in which there is not a legitimate profit, speculating on extra work to yield them a profit.

The result of this is obvious. Credits have been weak, and the bankers are exercising more care in discounting their paper. The dealers and manufacturers have less capital in their business, and contractors are unable to meet their payments promptly. And all this we can attribute to the demoralized condition of the electrical business to-day.

The question is, "What remedy have we?" Undoubtedly some of the readers of your valuable paper can offer some suggestions. A SUBSCRIBER.

THE PRECISION OF ELECTRICAL ENGINEERING.

THE failure to answer satisfactorily the question, What is Electricity? is usually counted against the electrical profession not only by those whose reading extends no further than the daily newspaper, but by those whose education ought to make such a question superfluous. The inability to answer the question has, however, instilled in the mind of the layman the idea that electrical science and the electrical arts are based on guesswork. As Prof. F. B. Crocker in his inaugural address before the American Institute of Electrical Engineers very happily puts it, the life of the electrical engineer is supposed to consist of a series of surprises and shocks to his mind as well as to his body. "The Precision of Electrical Engineering," which Prof. Crocker chose as the subject of his address, is thus an eminently timely one. Of course, as Prof. Crocker points out, the mere fact that we do not know what the essential nature of electricity is, cuts no figure in the application of the laws of the science, any more than our ignorance of what gravity is prevents us from applying its laws. But, as a matter of fact, Prof. Crocker contended, and, we believe, with ample proof, electrical engineering not only leads all other branches in the magnitude and rapidity of its results, but also in the exactness and certainty of its results. In proof of this he points out that such men as Franklin, Faraday, Ampère, Maxwell, Henry, Helmholtz, and a long list of others distinguished in electrical science were not men whose ideas were vague or incorrect. This alone would suffice tc establish the position taken, but if to this be added the rapid progress of electrical science and its applications, then, surely, enough testimony is at hand. Electric railroading and long distance electrical transmission are the development of only ten years' work. Surely, men groping in the dark could not have accomplished such work in such a brief space of time. The location of a fault in an Atlantic cable, or the design of a dynamo guaranteed before construction to give a certain output at a certain efficiency, demonstrate sufficiently the fact that so far as exactitude is concerned, electricity is the superior of any of its sister arts. Then, again, the uniformity of electrical units throughout the world, the accuracy and ease with which electrical measurements can be made without even interrupting the circuit, whether for the largest or smallest quantities, and the portability of the measuring instruments, all indicate a high stage of development of any science. We have given but a brief outline of the proofs advanced by Prof. Crocker, but enough has been said to indicate that he has well sustained his proposition. It would be venturing too much to hope that the prevailing misconceptions, as to the indefiniteness of electrical work, will be eradicated, but Prof. Crocker's address may impel workers in other fields to revise their inchoate opinions of the electrical engineer.

GOVERNMENT TELEGRAPHS.

WE note that the New Orleans "Times-Democrat" has begun a campaign in behalf of Government telegraphs, and has not only issued circulars on the subject, but has given up a large part of its space to the discussion of the topic. The agitation is being conducted with ability and moderation, and that journal, which has kindly favored us with files, etc., in regard to the matter, appears to be waging the campaign in full sincerity and conviction as to the propriety of the change.

It was, perhaps, impossible that any new arguments should be presented in this already long discussion, and we are not surprised, therefore, to discover a lack of novelty in the data before us. Apparently the "Times-Democrat" has trouble and expense in connection with its press matter, and it also does not approve of the closing of the offices at sunset in the smaller towns. These are certainly good and valid reasons for an agitation, but are they sufficient, or are all the reasons that have ever been urged sufficient for transferring the telegraph from private enterprise to Government monopoly?

We have ventured from time to time to answer this question with a very decided negative, and can now find no basis for a change in our views and convictions. We happen to be among those who think that most governments do most things badly, and that the people are happiest and best off who manage their own affairs with as little official control and management as possible. If there is any evidence to the contrary in the history of the nations we have failed to detect it. It is true that of late political doctrines and events have gone a long way toward State socialism, which means the abolition of private ownership and enterprise, but in due time the pendulum of opinion will swing the other way, leaving people freer than they ever were before, to handle and conduct their own business, and leaving the State a minimum of functions. Just now, somebody wants the community to own all the lighting plants; another person has his mind fixed on running all the street railways and all the larger railroads; this man wants the ferries to be seized, and that one proposes to nationalize all the mines of coal, iron, silver, copper and gold. Here is a man who fights for State telegraphs, and there one who would have the State issue a free daily newspaper for everybody. And so it goes. The chance of deficit, of local and national bankruptcy, bothers no one; nor in this country do the agitators of these things remember that their forefathers came here to escape this very State ownership or direction that they are so eagerly clamoring for.

Turning to the specific topic, we may join issue with the "Times-Democrat" that telegraphy in England and Europe generally is cheaper than it is here under the Postal, Western Union and other private companies. This we deny most emphatically. If the different purchasing power of money, different rates of salary, different distances, and different methods of counting the words, are taken into account, it will be found, as has often been pointed out before, that the advantage rather rests with us, plus the advantage of having no offensive official censorship put upon what one wishes to transmit. The "Times-Democrat" publishes every week lots of dispatches that neither love nor money could get over the wires for it if it were a European journal; and the espionage is, we believe, just as close as it was when Napoleon opened every letter passing through the mails to and from Spain. In this respect, the government telegraphs of Turkey and Germany are pretty much on a par; and if they or any of the other systems pay absolutely we have still to be advised of the fact.

The "Times-Democrat" proposes to put the telegraph in the hands of the postoffice. If we are not mistaken, that service

is now run actually at a heavy loss, and, of course, the deficit must be supplied from taxation. Of late, the money has necessarily been supplied, or rendered available by part of the bond issues, as the Government has not paid its way at all for some time past. Is the telegraph to be another source of financial embarrassment for the countrty? And what about the telephone? Is that to be overlooked? And does the "Times-Democrat" propose spending about $250,000,000 in purchasing these systems, or does it propose confiscation? The postal service cannot stand free competition, and every attempt is ruthlessly quenched, as at Buffalo quite recently; but the service remains so bad that we see no hope of improvement until private enterprise gives the public a chance to telegraph its letters cheaply by some "machine" method.

We would suggest to the "Times-Democrat" that some of the energy it has notably displayed on various interesting occasions might well be devoted by itself to getting the better news system it needs. The telephone is a marvelously effective news device, for example, and it could soon create a cheap system which would give its various correspondents the ear of the editorial room every hour in every twenty-four. But unless our contemporary wants to help convert all of us, whatever we do, into State officials, we beg it to refrain. The remark of Mr. Herbert Spencer comes freshly to mind as one notes all these desires for reform through the agency of Government control: "After ceaseless ridicule of red tape, the petition is for more red tape. Daily we castigate the political idol with a hundred pens, and daily pray to it with a thousand tongues." Our contemporary disclaims and flouts the suggestion of "socialism," but we would like to ask just where it sees the difference, and just where it expects the process to stop.

HALT AND RIGHT ABOUT FACE!

FOR a long time past, the prices of electrical apparatus have been on the downward plane. They no sooner reached a low point than deeper levels were disclosed, and the last four or five years have been spent in a desperate effort to find rock bottom. It is true that prices of other raw material and manufactured product have been far below the average, ever since the great panic of 1893, but the period of four years has seen marked rallies and advances in many staples, and to-day there are few that are not firmer than they have been for some time past. When we turn to electrical prices, no upward tendency has disclosed itself, and even now when in many lines there is renewed activity, the greater volume of business does not appear to carry with it any larger margin of profit. One of our readers calls attention to this state of affairs in the present issue, and indicates a belief that remedies for unprofitable trading could be found if they were sought. At this juncture, when returning prosperity is already sending prices up, it is a timely question that is asked. No one man, or concern, perhaps, can renew good conditions, but if there were harmonious action, business could be conducted on a fair margin of profit and the public would get better treatment and better goods.

The bids on some recent contracts in New York tell the story of undue competition. We could name one plant where six bids on dynamos, wiring, etc., ranged around $60,000 and the contract went at less than $52,000. In another case the wiring was bid on at $22,000 and the contract given at $15,500. In a third case, the highest bid for a fine new plant was $126,000, and the contract was closed at $98,000. In all these instances, the highest figure would have been considered a sacrifice a year or two back. What, then, are we to think of the lowest figures. Several questions are raised. Can some manufacturers and contractors do business so much better than others? It does not seem possible. The specifications in these plants were, we believe, drawn up by highly competent experts, with the utmost clearness, and it is hard to detect where these wide margins come in. If all are pretty much on the same footing, then profits are recklessly thrown away, and the credit and stability of the industry are proportionately endangered.

We shall be glad to know what our friends think about this. If these are to be times of prosperity, should not a halt be called on price cutting and an agreement be reached which will, at least, allow a living margin of profit?

FAN MOTORS IN LIBRARIES.

ANYBODY who has had much to do with books knows that it is no easy task to keep them dusted, and extremists, in view of the difficulty, have gone so far as to assert that you should never dust books. They should be left undisturbed till needed, and then the rust and dust of ages can be taken off with a napkin. This, however, is regarded as the heresy of sheer laziness, and the practical suggestion is now made that the fan motor is the thing wherewith to banish grime and dust from a well kept library. All that is necessary is to turn the breeze loose over the shelves, with the windows open, and in a few minutes the tops and covers will show up in all their pristine freshness. Obviously the fans can be portable, and either carried around in the hand by long flexible cord or hitched up at suitable plugs and left spinning. Thus dust will not be able to settle for long and will rarely have a chance to accumulate even for a single day. Electricity has, therefore, another claim to use in libraries. Gas is well known to have a deleterious effect on books, and Mr. Blades, the well known bibliographer, once said there was nothing to equal it for rotting covers, even those of leather. With electricity, a public or private library will be better lighted and better kept, while it will also be safely available more hours of each day.

TELEPHONIC GHOST VOICES.

A VERY pretty medieval story comes from the Folsom, Cal., penitentiary. Wilson and Prescott, convicts there, formed a plan to break jail some time ago. All preparations had been made and arms had been secreted outside the walls, when the plot was discovered. Wilson and Prescott were the only men who knew where the arms were. They were starved, kept in dungeons, and even tied up by the thumbs. but without results. At length the warden decided to place them one at a time in a cell in the condemned row, known as the "haunted cell." A wire was stretched from the captain's office to the cell, attaching it to a telephone transmitter. Wilson was the first victim. He was conducted to the room at midnight and an hour afterward the warden and his men in the telephone room of the office began to mutter sepulchral threats into the transmitter. They hissed, screamed and cursed and rattled chains on the telephone box, till far in the morning. When they went for Wilson at midday they found him badly scared, but still unwilling to talk. Then Prescott was tried. After a few days he weakened and told the whole story. He was nearly crazy when taken out.

This is a very charming episode, and should offer many suggestions to the police who are trying the "third degree" on criminals, in New York or Chicago. A new line of business is opened up for telephone exchanges, and it would obviously be more sensational and effective to get an accomplished elocutionist piped on from central, than to depend thus on the crude amateur efforts at spirit mediumship, of prison wardens and turnkeys. The idea might, perhaps, be tried in schools and residences where naughty children refuse to be quelled.

STREET CAR OWNERSHIP.

A PARTY of socialists in Atlanta, Ga., are demanding that the city take possession of and operate the street railways of the city. We would like to mention an item of news for their benefit, but are afraid it won't have much effect. Several references have appeared in our columns lately to the municipal street railways of Glasgow, Scotland, and the fact has been mentioned that they earn net for the city about $45,000 a year. The population is somewhere around a million. But Newark, N. J., receives from the Consolidated Company over $100,000, although the population is not above 250,000. On the basis of population, Glasgow should have received $400,000, or nearly ten times as much as its own municipal system netted for it. We have a suspicion that this is about the way with most municipal enterprises, but Glasgow has been flaunted in the public eye so long, it is time the hollowness of its claims to humble admiration was squelched by a few solid facts.

ELECTRIC TRANSPORTATION

THE HARTFORD, CONN., STREET RAILWAY CO.

THE Hartford Street Railway Company was organized July 21, 1862, and commenced running horse cars in April, 1864, having at that time about six miles of track and operating five or six cars. During the year 1895, the whole system was finally equipped with electricity, and at the present time the company owns and operates over seventy miles of track. The equipment consists of seventy-eight closed and eighty-nine open cars. There are run daily sixty to sixty-five cars, which make 8,000 to 9,000 miles. In the year ending September 30, 1896, the cars of this company were run 2,814,072 miles, and carried 10,854,971 passengers.

LINES.

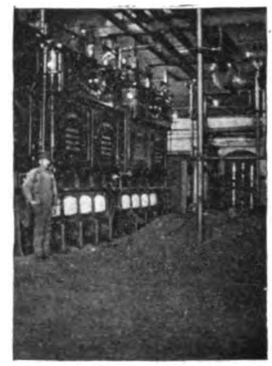
As will be seen by the map, the lines cover nearly every part of the city, and reach out to many of the surrounding towns, i. e., Wethersfield, West Hartford, Windsor, Poquonock, Rainbow, South Windsor, East Windsor Hill, Burnside, and North and South Glastonbury. At West Hartford, connection is made with The Hartford & West Hartford H. R. R. Company, whose lines extend to Farmington and Unionville. At Burnside, connection is made with The Hartford, Manchester & Rockville Tramway Company, whose lines extend to North and South Manchester and Talcottville, and a line is under construction to Rockville.

The Hartford Street Railway Company has been building a line, which opened up in June, that extends to the City of New Britain. Here connection is made with The Central Railway and Electric Company system, whose lines extend to Berlin and Plainville, there connecting with the Bristol and Plainville Tramway Company, with lines to Bristol, Forestville and Compounce Pond.

POWER HOUSE.

On May 2, 1894, it was decided to purchase from the Woodruff and Beach Iron Works the property No. 72 Commerce street.

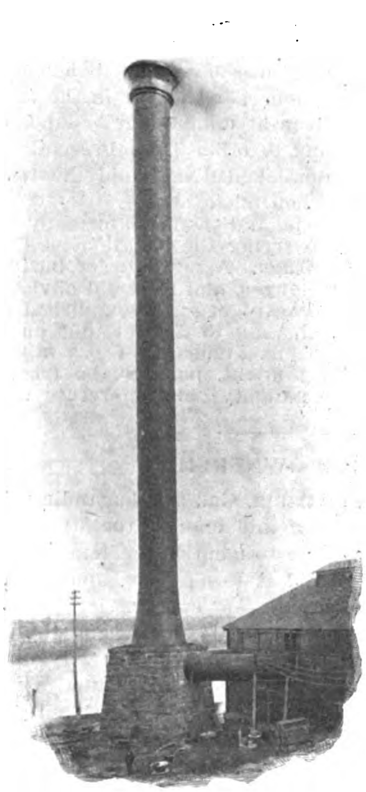
POWER HOUSE DURING FLOOD, MARCH 3, 1896.



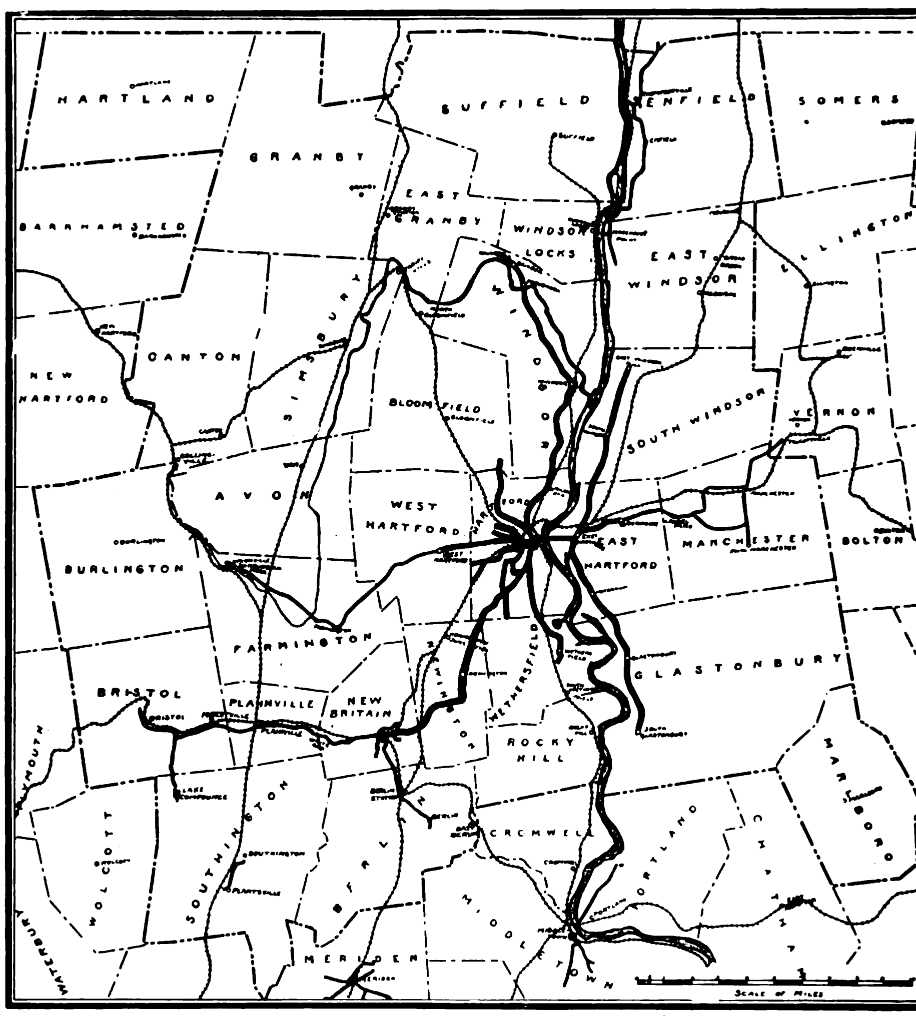
BOILER ROOM.

Owing to the annual floods in the Connecticut river, it was necessary to locate the engine and boiler rooms at a safe elevation above the highest known flood, which, on May 1, 1854, reached the height of 29 ft. 10 in. above mean low water. The accompanying illustration of the power house shows the front, with a flood of 26.5 ft. above low water on March 3, 1896.

In order to exclude the water from the portions of the build-



CHIMNEY.

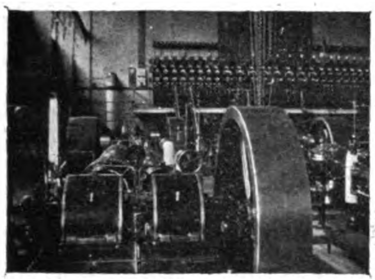


MAP OF HARTFORD AND SUBURBAN RAILWAY SYSTEM

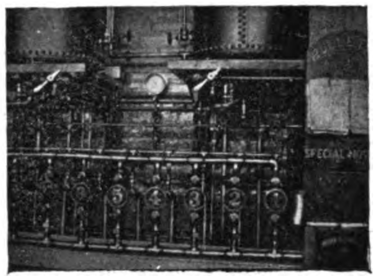
ing below the high water marks, principally the condenser pit, the bottom of which is only 11 feet above low water, it was necessary to re-enforce the old foundry foundations with a concrete wall 12 inches thick. This device has been most satisfactory.

The power house is a brick and iron building, 230 ft. x 63 ft., built by the Berlin Iron Bridge Company. The third section, which is 65 ft. x 63 ft., is divided into offices, stock room, work shop and wash room for the employés.

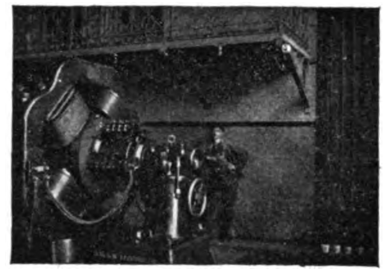
The engine room occupies the middle section, with a floor space of 100 ft. x 63 ft. The floor is composed of 4-inch yellow pine, covered with 1⅛-inch maple, supported by 12-inch I beams. The room is spanned by a crane of ten tons capacity, built by the Berlin Iron Bridge Company. The third section, 65 ft. x 63 ft., is the boiler room.



ENGINE ROOM.



OIL DISTRIBUTING APPARATUS.



GENERATOR.

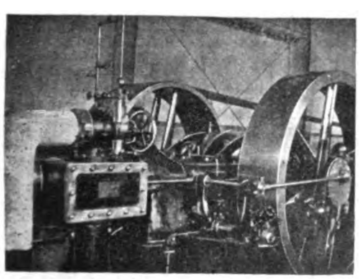
ENGINE ROOM.

The engine room equipment consists of eight 300 horse-power, cross-compound, condensing, Ball and Wood engines; eight M. P. 220 kilowatt General Electric generators; four 12 in. x 15 in. x 10 in. Worthington independent jet condensers, and two 9½-inch Westinghouse air pumps.

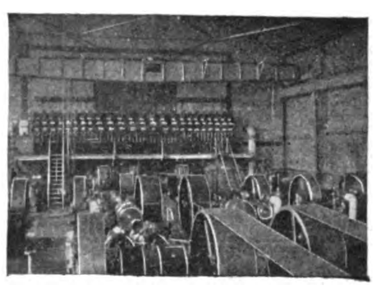
The principal dimensions of the engines are: Dia. horse-power cylinders, 14 inches; dia. low pressure cylinders, 27 inches; stroke, 16 inches; dia. governor wheels, 84 inches, face 17 inches; dia. balance wheels, 84 inches, face 29 inches; speed, 210 revolutions per minute; steam pipe connections, 6 inches; exhaust pipe connections, 9 inches. The belts are the Jewell, oak tanned, double railway dynamo type, 66 feet long and 26 inches wide.

The switchboard, which is placed on a gallery at one end of the engine room, is of the General Electric type, and consists of eight machine panels, form K, and sixteen feeder panels, form C. Each feeder panel is equipped for two feeders.

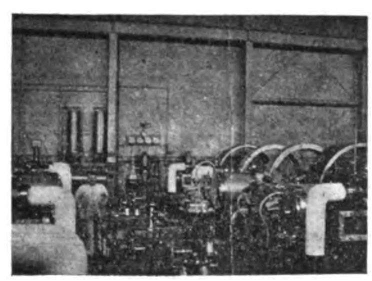
The condenser pit is situated beneath the center of the engine room, and is 19 feet below the floor of the latter. In it are placed four condensers and the receiver of the Holly gravity return system. All the steam mains are beneath the engine room floor, and are carried on concrete piers.



BALL & WOOD ENGINE.



ENGINE ROOM, SHOWING SWITCHBOARD.



ENGINE ROOM, SHOWING OILING SYSTEM.

BOILER ROOM.

The boiler room equipment consists of eight 300 horse-power Heine safety water tube boilers, two Worthington duplex 10 in. x 6 in. x 10 in. feed pumps, two No. 12 Monitor injectors, two No. 19 American feed water heaters, and two Spencer damper regulators.

The boilers are arranged in two batteries, facing each other, with the steam mains and connections supported on an iron structure directly over the space between the batteries. The steam mains are so arranged that each battery of boilers is entirely separate from the other. All the feed water pipes are brass, with cast iron fittings.

The principal dimensions of each boiler are: two shells, 36 inches dia., 19 ft. 3 in. long; 171 lap welded, 3½-inch tubes, 16 feet long; grate surface, 9 ft. x 6 ft., with 50 per cent. air space; 130 lbs. working pressure. The smoke flues are 88 inches in diameter where they enter the stack. The stack, which is self-supported, was made and erected by The Coatesville Boiler Works Company. It is 191 feet high and is made of ⅝-in., ½-in., ⅜-in. and ¼-in. steel plates, lined to the top with brick, with an inside diameter of 10 feet. The stack and lining weigh 350 tons. The Portland brown stone foundation, which was built by D. F. Keenan, weighs 1,500 tons.

The fire department apparatus consists of a Worthington Underwriters 16 in. x 9 in. x 12 in. duplex pump of 750 gallons per minute. The power house is heated by the Evans Hot Water System, which consists of the necessary coils and radiators, a 60 horse-power pipe heater and a small Worthington circulating pump.

OILING SYSTEM.

The lubrication of the machinery in the engine room is accomplished by an automatic gravity oiling apparatus designed and patented by the chief engineer, Mr. Frank Caum, and consists of a distributing and mixing device in the engine room and a filter and storage tanks in a separate building. The mixing device consists of two 60 gal. tanks and a combination of pipes and valves, by means of which either new or filtered oil or the two mixed can be fed to any engine. The supply of oil from the storage tanks to the engine room is controlled by a valve in the oil house, but which is operated from the engine room. Means are provided by which all the oil in the engine room can be forced to the oil house or out doors in case of fire. The filter and storage tanks are placed in an oil house, which is a brick building located in the rear of the boiler room. All oil is handled by means of compressed air.

Water from the Connecticut River is used in the boilers and for condensing purposes. The fuel used is George's Creek Cumberland coal, and is received in barges via Connecticut River.

A recording wattmeter registers the work done by the station. The daily output at present averages 11,100,000 watt hours. The average amount of coal consumed per day is 50,000 pounds.

ACCUMULATORS FOR ELECTRIC CARS.

The directors of the Hanover (Germany) tramway system have published an important report, in which they narrate their experiences with accumulators as the source of the power for their cars. In Hanover both overhead wires and accumulators have been used for a considerable time, so that the managers are in a position to institute a reliable com-

parison. Taking everything into account, they pronounce in favor of the storage cell. The cost of maintenance they say has been determined with the utmost exactitude possible for the year 1896, and the managers reach the conclusion that the additional cost of accumulators does not exceed 1 groschen, or 0.2c. per mile. Consequently, it has been decided that the entire system shall, as soon as the requisite arrangements can be made, be driven by secondary batteries.

THE SPRAGUE MULTIPLE UNIT TRACTION SYSTEM.

In our last issue we gave a very full account of the experiments made by Mr. Sprague at Schenectady on cars of the South Side Elevated Railroad, of Chicago, equipped on his system of multiple unit operation and control. With this system, it will be recalled, each car is equipped with its own motors and any number of cars can be coupled together to form a train, which can be completely controlled from the platform of any car constituting the train. Automatic devices are employed which make it impossible for the motorman to waste current at starting, or to lose control of the train.

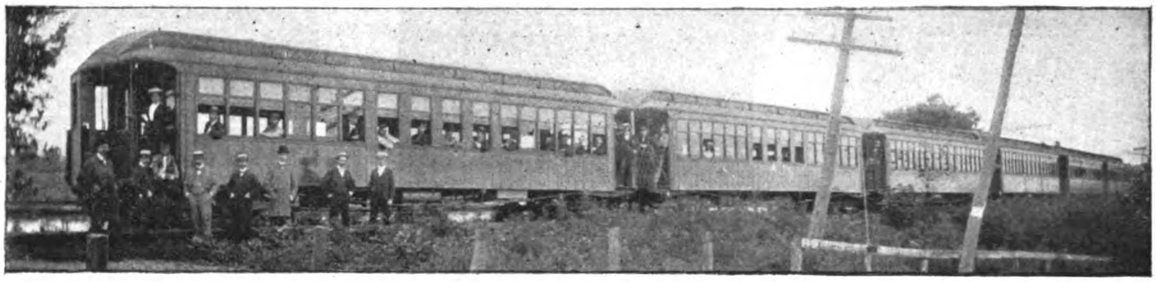


Fig. 1.—Train of Six Cars at Schenectady, Controlled by Sprague Unit Multiple System.

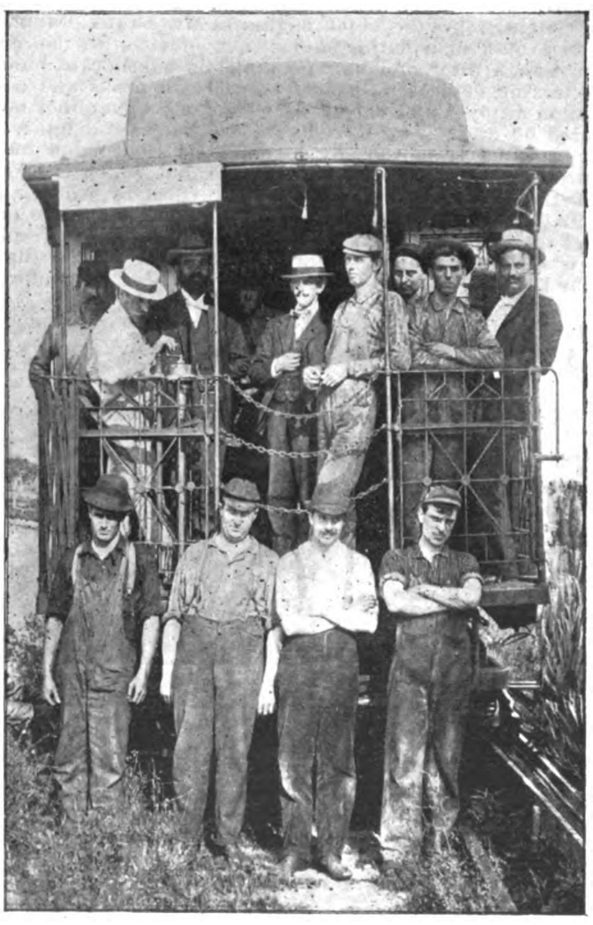

Fig. 2.—End of Car, Showing Suspension of Control Mechanism and Position of Levers.

The accompanying engraving, Fig. 1, shows a view of the six-car train used in the tests at Schenectady, Fig. 2 showing the end of a car with the automatic regulating devices hung from the canopy of the car platform. The controller and air-brake handles are shown at the left next to the platform rail.

ELECTRICITY AS A MOTIVE POWER ON ELEVATED RAILWAYS.—I.

BY PROF. S. H. SHORT.

The elevated railways of New York, Brooklyn and Chicago were built to satisfy a crying demand for rapid transit from the business centers to the suburban districts of these great cities. So long as they had for their only competitor the slow moving horse car, they were considered a great convenience, notwithstanding that one was obliged to walk from one to three blocks and climb a difficult flight of stairs to reach these rapidly moving trains.

Since the "trolley car" has come into general use, people have been educated to a still more rapid rate of travel, and where the trolley car parallels the elevated railroad, as in Brooklyn and Chicago, the frequent, speedy and accessible surface car is, by far, the more popular. In New York, however, the elevated railways still enjoy a very large traffic, be-

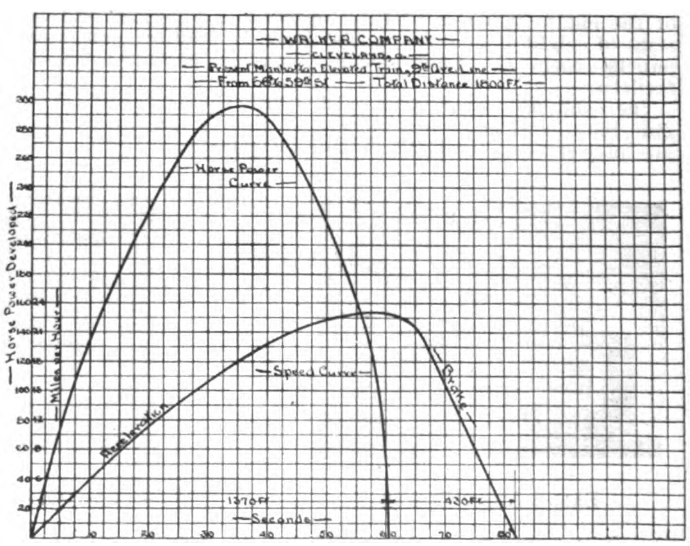

Fig. 1.

cause the electric cars do not parallel their lines, nor are the facilities for transportation yet sufficient for the enormous masses to be moved back and forth in that city. However, the surface lines are soon to be equipped electrically, and their carrying capacity thereby enormously increased to the detriment of the elevated railway travel. In order to retain their traffic, it will be necessary for the elevated railways to move their trains more frequently, and at a much greater rate of speed, to compensate the traveling public for being obliged to walk some distance and climb those disagreeable stairs.

It would add greatly to the travel on these roads, were some plan devised for mechanically lifting passengers to the elevated stations.

The elevated roads are all built on the same general plan, the structure being provided with double track throughout the entire length, with stations about one-third of a mile apart. The grades are slight, and the curves of not less than 90 feet radius. The structure is made to safely carry the standard elevated train, i. e., five passenger coaches, each 48 feet in length, weighing, when loaded with seventy-five passengers, 20 tons, drawn by a locomotive weighing 23½ tons, making a total of 123½ tons for the complete train.

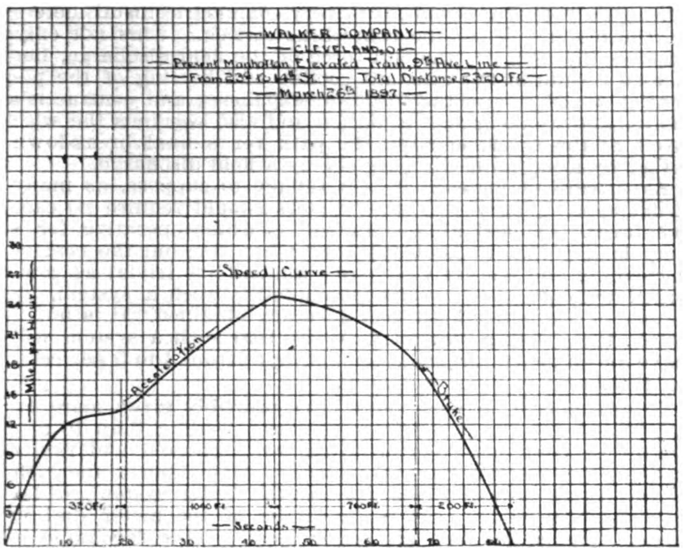

FIG. 2.

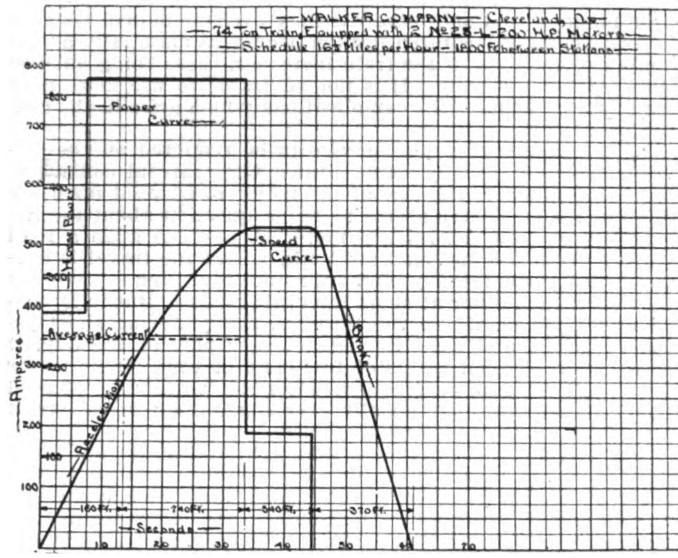

FIG. 4.

The locomotives are constructed so that 65 per cent. of their weight, or 15¼ tons, are upon their drivers, giving an adhesion, and therefore a maximum horizontal effort for accelerating the train, of 7,650 lbs. This effort is utilized for accelerating the train for 50 or 60 seconds, and a speed of 20 to 25 miles per hour is attained, while a maximum of 300 h. p. is developed by the locomotive. The brakes are then applied with a negative acceleration and the train is brought to a standstill at the next station, where it remains on an average of thirteen seconds.

In the accompanying diagrams (Figs. 1 and 2) I have illustrated graphically the performance of one of these trains between stations, also the consumption of power, as calculated from the weight and speed of the train. It will be seen therefrom that it is not possible, with steam, to make a better schedule time than is at present in force, i. e., 13½ miles per hour, unless the weight of the locomotive be increased or the trains be lightened. The heavier locomotives would endanger the safety of the entire structure. The lighter loads would necessitate more frequent trains, consequently a much larger force of skilled employés to run the extra locomotives. The cost of fuel for operating a steam locomotive amounts to about 20 per cent. of the total operating expenses of these roads, the fuel consumption being about 7 lbs. to 8 lbs. of coal per horse-power per hour.

With good compound condensing engines, driving electric generators at a station, the coal consumption is reduced to about one-third of that amount.

Were steam locomotives discarded, it would be possible to replace the high-price skilled labor, necessary for their operation, by ordinary trustworthy men, who are not skilled mechanics; whose rate of wages is about one-half that of a locomotive engineer, and only one man would be necessary to operate the electrical propelling mechanism. We believe the repair account will be materially lessened, both in the units of motive power and in the permanent way, were the trains equipped with motors. The care of a steam locomotive is very onerous, the average run being only about 100 miles, when it must be thoroughly overhauled and inspected by skilled mechanics before being used again. Contrast with this the all day service of most electric motors, 200 or 300 miles a day for days and weeks, without inspection, cleaning or care of any kind.

The standard electrical equipment for an elevated train consists of the present elevated car, as illustrated in the accompanying diagram (Fig. 3) provided with two swiveled trucks of special construction, arranged to receive electric motors of a type adapted especially for this service. The wheels of the trucks are 33 inches in diameter, and the wheel base does not exceed 6 feet for the largest motors, and is reduced to 5 feet 6 inches, where motors of the smaller size are used. The weight of the motor car, loaded to its full capacity with passengers, is 32 tons, including trucks, motors and the electrical equipment. In most cases it is advisable to use only two motors upon a motor car, and both should be placed on one truck for convenience in repairing. There is, therefore, 19½ tons upon the drivers, or 61 per cent. of the total weight of the motor car, which corresponds favorably with the percentage

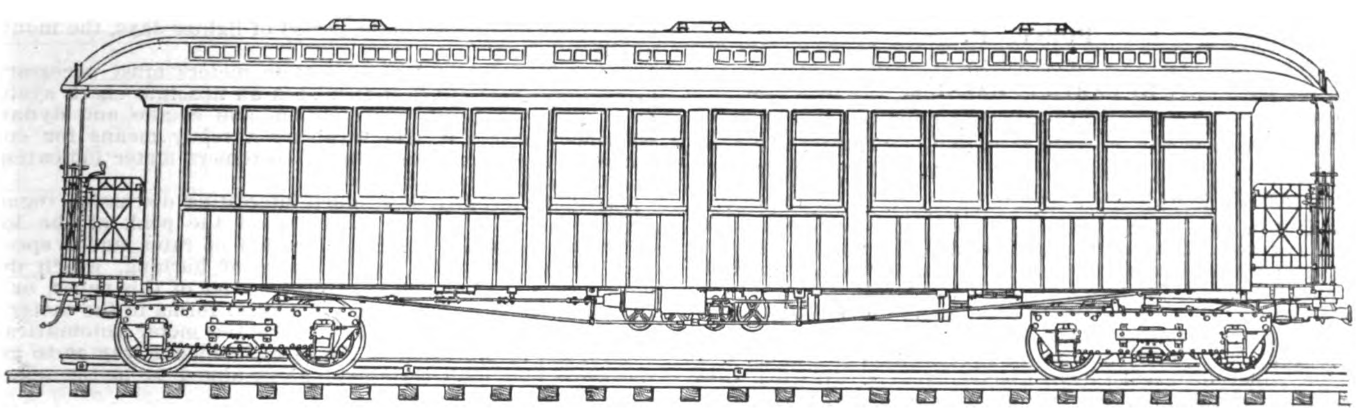

FIG. 3.

of the total weight of passenger locomotives upon their drivers. This gives an adhesion, and therefore a maximum practical horizontal effort, for the motor of 9,750 lbs., or, a total horse-power of 400, in accordance with standard motor rating.

This pair of motors is, therefore, capable of accelerating a train of three standard elevated cars, at the rate of 1.85 feet per second, and of making a schedule of 16½ miles per hour, including stops, as illustrated graphically by the accompanying diagram (Fig. 4).

If the other truck of the motor car is also equipped with motors, a train of double this size will operate in exactly the same manner, and one more car may even be added, because the tractive effort required per ton decreases materially as the number of the cars in the train increases, there being but one motor car on the train. It is not advisable to use more than two motors, owing to the complications which arise in the controlling devices.

The requirements of the service to be rendered on the different elevated railways necessitates very careful consideration being given to the size of the motor to be used upon the different roads. There seems to be no question about the advisability of using as large a motor as possible upon a road like the Sixth Avenue, in New York, where the travel is constant throughout the day, and trains of from four to five cars can follow each other at short intervals all day. But in Brooklyn and Chicago, where the traffic is heavy during short periods of time, and light during a larger part of the day, it seems desirable that trains of few cars, or even single motor cars, shall be run at frequent intervals without a printed time table; thereby practically securing a high speed street car service on the elevated structure.

Another reason for frequent and light trains, is that these roads have branches, which, by this method, would be served to better advantage. It is possible, also, that these single motor cars or short trains may be coupled into longer trains during the rush periods of the day, and be operated from the front platform by one motorman, if a suitable controlling apparatus is provided, by means of which all of the motors of the train can be simultaneously controlled.

A motor of much smaller size than would take up the full adhesive power of the truck could be used, where this method of equipment is adopted. It has, however the disadvantage of multiplying the electrical apparatus necessary to move the rolling stock of the road. It will also consume more power per ton-miles of train, because the tractive effort per ton of the trail cars is about half that required by the motor cars, the difference being due to the friction, windage, etc., of the motor cars.

MISCELLANEOUS

ELECTRIC METERING FROM THE STATION STANDPOINT.—II.

(Concluded.)

BY CARYL D. HASKINS.

THE methods which are commonly practiced in tampering with meters can scarcely form any proper part of a technical paper; but as this paper may go into the hands of some who need the knowledge to guard themselves and their interests, it can do no harm to briefly state the common methods used, not only that they may be guarded against, but also that meters may be selected which lend themselves least readily to such practices. It is not unusual to place large masses of iron above, below or at the side of meters, but this practice is falling somewhat into disrepute among its advocates, since even they have in time discovered that there is a class of meter which it accelerates. Electromagnets, drawing their energy from the circuits under measurement and used as the iron was formerly used, are now not uncommon, and it is difficult to prove in court deliberate evil intent. Meter covers and bases are drilled and wires, broom straws and the like inserted. Covers are pried up and healthy colonies of spiders introduced. Ingenious individuals have even been reported as finding profit in a clever apparatus for injecting fine iron filings into meters by means of a bellows.

The most radical cause of trouble in connection with installation is vibration and the consequent reciprocating motion of the shaft; for this reason the most solid of foundations should be selected, the neighborhood of moving machinery should be avoided, as should also partitions of light construction in which doors are located. The rhythmic vibration of moving machinery is infinitely more dangerous than occasional heavy shocks. Meters should be installed as near to the foundation as possible, not as is now quite common, at the top of buildings, where the amplitude of all vibrations is of course much greater. Locations where great variations of temperature occur are undesirable. For this reason, also, basements are preferable to attics.

A very common error, causing the loss of very many meters annually, by the burning out of the potential circuits, occurs in connection with the metering of power delivered to motors. In the effort to save the very trivial amount of energy passing through a potential circuit, it is very common to instal meters on the motor side of the controlling switch. This not only exposes the meter to the full force of the field discharge, but it also results in the constant cooling and heating of the potential winding, and the resultant expansion and contraction chafes and weakens the insulation and also weakens the wire itself at the turns, opening the path for a final breakdown either by a lightning discharge or by a field discharge.

As to care of meters. It is a fallacy to suppose, as many insist upon doing to-day, that meters should require no care whatever. Almost all meters will continue operative for a very long period without any care whatever; but the cost of a cleaning and testing visit twice annually is trivial as compared with the good results which follow such a system, by reason of the better light load accuracy obtained. It is not, I think, too strong a statement to say that such a system will have an influence for good, amounting to from 3 to 5 per cent. on the meter readings annually.

Central station managements have probably given more attention to systematic methods of meter reading than to any other one point contributing to success. The old and faulty plan of reading the dials of a meter at the time of the visit to the meter, is fast giving place to the better system, which provides the reader with a fac-simile of the meter dial in blank upon a page of his meter book. This fac-simile is roughly marked in pencil to indicate the position of the hand at the time of the visit. These fac-similes are taken into the office and are all read by one individual who is an expert in meter reading, and who sets down the consumption under the fac-simile on each page. Such a system commonly reduces the errors from about 10 per cent. per month where they not uncommonly stood under the old system, to materially less than 1 per cent. under the new; for, surprising as it may seem, it is an extremely easy thing to make mistakes in reading meter dials.

In changing from the old and not infrequently popular contract system, a good many central stations in the earlier days made the grave blunder of going on to the new basis during the winter months, with the result that the highest bills of the year reached the customer after a long period of indulgence under the contract system, and the result at times proved temporarily disastrous.

I have lately been much impressed by a system which was recently adopted by a prominent Western company to at least partially offset this difficulty. During the months which are growing darker, they read their meters a day or two earlier each month, thus arbitrarily creating shorter months, while as the year progresses to the period of lighter days, the months are lengthened.

The value of a system of station meters must necessarily prove very great, since it furnishes an absolute check system upon coal and water consumption, and engine and dynamo efficiency. While it also furnishes a ready means for comparison between station output, customers meter indications, line losses, leaks and grounds.

There has recently been much interesting discussion regarding the question of the flattening of the peak of the load either by the systematic modification of rates under special time contracts, governing the hours of burning, which does not concern the immediate subject matter of this paper, or by an actual modification in one of several forms in the meter itself, which should practically make the meter automatically control the modification of the rates in such a way as to gain the same end with certainty, as is aimed at in the special contract system.

It is quite obvious that the best double rate meter will be that which tends to flatten the load curve of the station, not by oppressing or discouraging the user of light, who must have his light at the period of the peak, so much as by encouraging the use of light at other periods. We do not want to provide means for cutting off the peak so much as we want means for raising the rest of the curve to the same height as the peak. In my personal opinion, it is in this respect that perhaps the most ingenious of all these double rate meters falls short.

If two-rate meters are to be used, I believe that their increased proportional speed should be dependent purely upon the occurrence of the station peak, and should bear no rela-

tion whatever to the occurring of the local peak. Such an arrangement can be secured in a number of ways, all of them simple and all of them effective.

One other feature of metering, which has recently come into existence in Europe, is about to make its appearance commercially in this country. It brings with it much of promise for the increase of profitable business for central stations. I refer to the prepayment meter system, the drop-a-nickel-in-the-slot and get-your-money's-worth-meter. In gas practice this system has proved an unqualified success. I am informed that the London Gas Light Company added 6,000 new customers of a profitable kind over and above their average annual growth in a single year; and other companies have had similar experience.

There is in every large city a considerable area into which illuminating companies have been unable to go by reason of the untrustworthy character of the people who would there be their customers. In other words, because the people in these districts are a floating population without credit, coming to-day and going to-morrow, and yet ready and willing to buy electric light at high rates. The prepayment meter throws open this new field and makes it immediately available; and here I predict for it wide usefulness.

THE ALTERNATING CURRENT INDUCTION MOTOR.—II.

BY CHAS. PROTEUS STEINMETZ.

If besides high resistance the motor has high admittance also, as No. 3 in Fig. 5, the high efficiency maximum at light loads is cut off and the efficiency curve flattened and lowered. The power factor rises very slowly at light loads, reaching a lower maximum. Characteristic, however, remains the large drop in speed, while the exciting current has increased very greatly also.

The reverse, a high reactance motor, is motor No. 4, shown in Fig. 6. Characteristic of this motor is the constancy of speed, 3.3 per cent. drop at full load, and especially the efficiency curve, which rises slowly, but reaches a fairly high maximum at or rather above full load. Power factor and apparent efficiency are low, with maxima beyond full load, and rise very slowly; that is, are poor at light loads. As seen, such a motor is in general unsatisfactory and may be less objectionable only in special cases, where it is running constantly at or near high admittance by high exciting current and poor power factor and apparent efficiency at light loads.

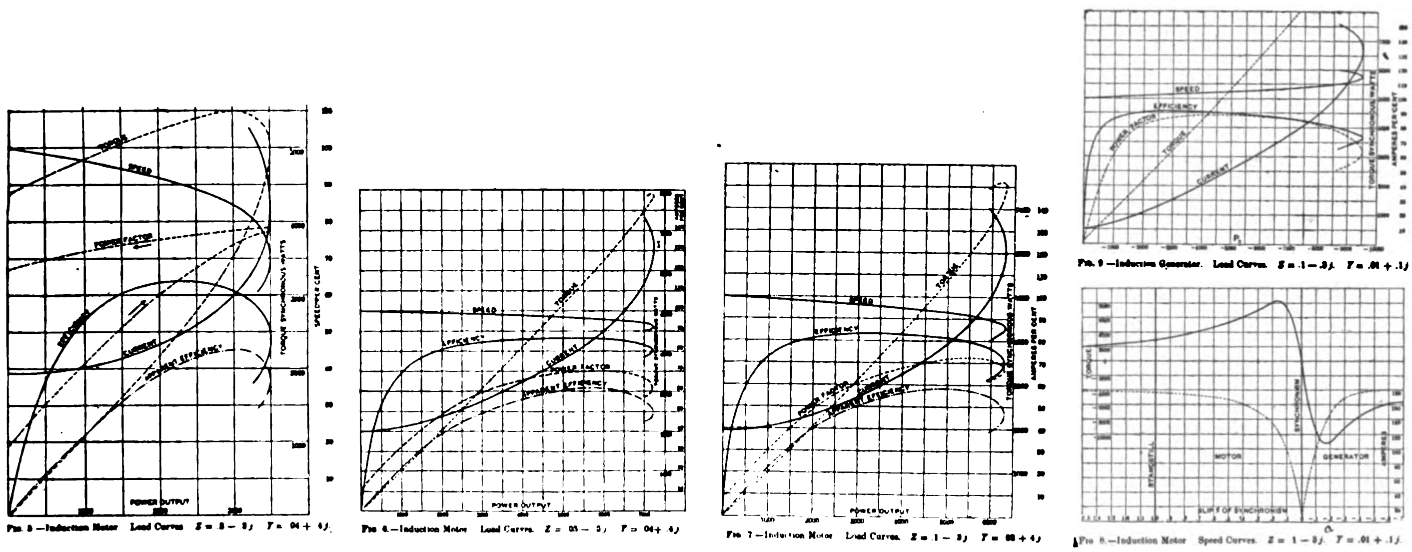
An abstract of the data of these motors and a number of other motors is given. (See table, page 85, of last issue.)

Speed Curves.—The load curves discussed in the preceding are especially characteristic of the action of the motor when doing work at its proper speed near synchronism. The action in starting, or in running at intermediate speeds, or beyond synchronism, or when driven backward, are best shown by what I may call the speed curves of the motor. A set of such curves, corresponding to the motor, No. 1 in Fig. 3, are shown in Fig. 8. These curves give with the speed; that is, the slip, as abscissæ, the torque in watts at synchronism and the current input of the motor. As seen, the torque is zero at synchronism, increases with increasing slip; that is, decreasing speed, reaches a maximum of 8,250 synchronous watts at 16.5 per cent. slip, and then decreases again, reaching 2,920 synchronous watts at $s = 1$; that is, standstill, and keeps on decreasing for $s < 1$; that is, backward rotation, without change of direction, thus representing consumption of energy by the motor. The negative or generator part of the torque curve is higher than the positive or motor part; that is, driven as generator above synchronism the machine consumes more mechanical torque than it produces running as motor below synchronism. Thus, the induction motor shares with the continuous current shunt motor the feature to be a motor only below a definite speed, but to become generator or act as brake by returning energy into the line, when driven above its speed.

The load curve of the motor corresponds to the part of the speed curve between synchronism and maximum torque at positive slip. From the part of the speed curve between synchronism and maximum torque at negative slip, or above synchronism, a corresponding load curve can be constructed of the machine as induction generator. This curve is shown in Fig. 9. As seen, it is very similar to the motor load curve, except that the speed curve bends upward.

To derive a certain value of current from the induction generator, the total load put on it must have the particular power factor corresponding to this current, and besides leading current, or if the power factor of the load changes, current and voltage of the induction generator will change accordingly. In consequence thereof, in general the induction generator is stable only, if at least a part of the load consists of synchronous motors.

The current in the induction machine is a minimum at syn-



FIGS. 5, 6, 7, 8 AND 9.

full load, or where very close speed regulation is required and wattless currents less objected to.

No. 5, in Fig. 7, shows a high susceptance motor. This motor is characterized by good efficiency at light loads as well as heavy loads, but power factor and apparent efficiency are very low at light loads and rise very slowly and reach their maximum only at or above full loads.

Comparing the different motors with each other, we see that a good motor is characterized by high values of power factor, efficiency and apparent efficiency at light loads, as well as heavy loads, by fairly close speed regulation and low exciting current.

High resistance is characterized by poor speed regulation and lowering of the efficiency at heavy loads, high reactance by very good speed regulation, good efficiency at heavy loads and low power factor and apparent efficiency at light loads, chronism and decreases on either side of synchronism, first very rapidly and then slower, and becomes fairly constant afterward, as seen in Fig. 8. In the particular motor under discussion, the whole variation of current is practically comprised within the range from $s = + 4$ to $s = - .3$, s being the slip. That is, the current at standstill is very large and remains practically constant until about ⅔ of synchronous speed is reached. Thus, such a motor with low armature resistance will require a very large current, not only in starting, but also at intermediate speeds.

As seen from the preceding, the motor No. 1, while very satisfactory at speed, requires excessive current and gives little torque at low speed and in starting, and is thus unsatisfactory therein.

An increase of armature resistance, r_1 produces a proportional increase of slip, n, and thereby corresponding decrease

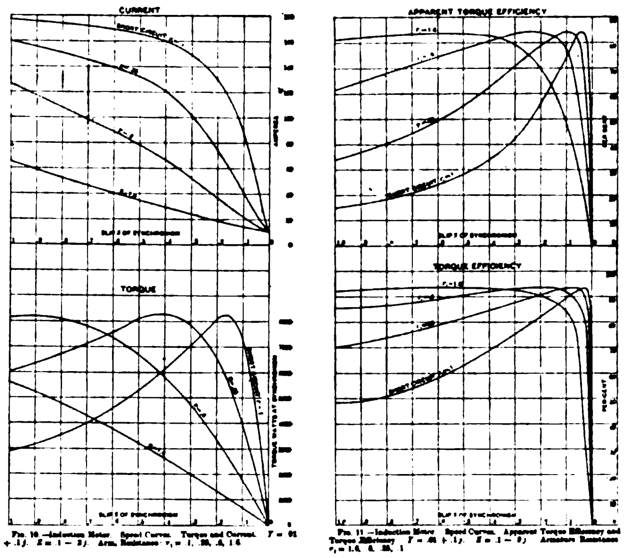
of power, efficiency and apparent efficiency, but does not change the torque, current and power factor.

The insertion of resistance in the armature or secondary of the induction motor offers a means to reduce the speed corresponding to a given torque, and thereby any desired torque can be produced at any speed below that corresponding to armature short circuit, without changing torque or current. Hence, given the speed torque curve of a short-circuited motor, the torque curve with resistance inserted in the armature can be derived therefrom directly by increasing the slip in proportion to the increased resistance.

This is done in Fig. 10, in which are shown the speed curves of the motor No. 1 between standstill and synchronism.

On the same diagram, Fig. 10, are shown the currents corresponding to the different values of secondary resistance.

The apparent torque efficiencies of the motor under the four



FIGS. 10 AND 11.

conditions of armature resistance are given in Fig. 11. They show that, although a considerable starting torque can be reached by a moderate armature resistance, of $r_1 = .25$, the apparent torque efficiency or torque per ampere input is still very low under this condition; that is, the motor starts very inefficiently, and, as seen in the preceeding discussion of high resistance motors, is rather inefficient at speed. The same diagram also shows the torque efficiencies. It follows herefrom that permanent resistance in the armature of an induction motor can be used to secure good starting torque at the sacrifice of current in starting, and of efficiency and speed regulation when running, but cannot be used to limit the starting current, the latter requiring so large an armature resistance as to make the motor entirely unfit when running.

CARBORUNDUM ABROAD.

A NEW carborundum plant has been established in Dresden, Germany, as a result of the visit of Mr. E. G. Acheson, president of the Carborundum Company of Niagara Falls, to that place. Mr. Acheson has returned from his European tour, and reports good success. He states that a local company will operate the Dresden plant of 400 h. p., and that it will be run by current obtained from the municipal lighting plant of Dresden, which is operated by steam, but, despite this, Mr. Acheson looks for good returns from the German plant. The new factory will supply the German trade with carborundum in bulk, and will not manufacture it into wheels, etc., but the manufactured carborundum will be supplied from the Niagara Falls plant.

While in England Mr. Acheson established an English agency for the sale of carborundum in London, and prospects are that very soon they will receive very large orders from there, which will be filled from Niagara Falls. The Niagara Falls factory is very busy now, and the additional trade of which the company is assured will add to the activity of the plant.

The carborundum furnaces in use at Niagara Falls to-day are about 6 feet wide and 16 feet long. They are burned 36 hours instead of 24, as at the start. The average product is about 4,200 lbs. a day, and the product of the company finds a very ready market. Mr. Acheson's success while in Europe is exceedingly gratifying to those interested in business with him at the Falls, and his return was hailed with pleasure. Mr. Acheson makes his home in Buffalo, but both he and the other officials of the Carborundum Company are held in high esteem by the business men of Niagara Falls, where they transact business daily.

MECHANICAL

COAL PRODUCTION IN THE UNITED STATES.

THE compilation of the statistics of coal production in the United States in 1896, which has just been completed by Statistician E. W. Parker, of the United States Geological Survey, shows that the product in 1896 was 190,639,959 short tons, valued at $195,557,649, against 193,117,530 short tons, valued at $197,799,043 in 1895, a decrease of 2,477,571 short tons in amount and of $2,241,394 in value. The decrease in product was entirely in that of Pennsylvania anthracite. The output of bituminous coal shows an increase of about one and three-quarters million tons. The anthracite product of Pennsylvania decreased nearly four and a quarter million tons. It is a notable feature, however, that there was a decrease in the value of the bituminous product of over $1,600,000 notwithstanding the increased output and that there was a comparative increase in the value of anthracite, although, on account of the smaller production, it did not equal the value in 1895. The average price obtained for anthracite at the mines increased from $1.41 in 1895 to $1.51 in 1896. The average price for bituminous declined from 86 cents to 83 cents.

Among the important bituminous coal producing States, Pennsylvania, of course, stands first, with an output of nearly 50,000,000 tons. Illinois is an easy second with nearly 20,000,000 tons, or more than 75 per cent. of the combined product of West Virginia and Ohio, which come third and fourth, respectively. The race between Ohio and West Virginia was very close in 1896, there being but a thousand tons difference, and the output of each nearly 13,000,000 tons. These four States yield about 70 per cent. of the total bituminous production.

Pennsylvania's bituminous product was a little more than a million tons less than in 1895. Ohio lost 480,000 tons. West Virginia increased her output about 1,500,000 tons, and Illinois about 2,000,000 tons. The other important States showing increased production were Alabama, Arkansas, Colorado, Indian Territory, Kentucky, Maryland, and Texas; while Indiana, Iowa, Kansas, Missouri, Montana, New Mexico, Tennessee, Utah, Virginia, Washington and Wyoming showed decreased production. West Virginia had the most important increase among the Appalachian States, Illinois in the Middle West, and Colorado was the only State in the Rocky Mountain region whose production increased.

COST OF STEAM POWER IN NEW ENGLAND MILLS.

IN our issue of July 22 we published the figures of cost of steam power in New England mills, as arrived at by Mr. F. P. Sheldon, consulting engineer for the West End Railway Company, Boston. In commenting editorially on the results arrived at by Mr. Sheldon we expressed doubts as to the correctness of the low figures arrived at, and in reply to a private communication we have received the following from Mr. Sheldon:

My figures were not in any sense "results arrived at by me" in some mysterious manner, but simply taken from accounts whose integrity I have no reason to question, and which were not made up with any anticipation of ever being shown, and we do not consider them so amazing as you seem to. On the other hand, we should consider amazing a compound steam engine plant of 1,000 h. p., which would cost for fuel $10.69 per year with coal at $3 a ton for power alone for 3,080 hours. I have accounts from another mill where coal is $4.10 per ton, and the cost per horse-power per year for fuel is $9.10, and I believe tthe accounts are faithfully kept, as I am personally acquainted with the men who keep them.

Here is another case which may interest you: A mill in

New England, with coal at $3.84, and all the fuel for heating the buildings in our winters (with over 150,000 square feet of floor space in them), besides steam for sizing yarn, cost per horse-power per year for fuel $9.69; and total cost in this mill, including labor, supplies, repairs and fixed charges (same as given in my other figures) $17.89 per horse-power per year of 3,080 hours. This with coal at $3.84, and including heating, which is no small item in this climate.

You can see that if coal at this mill were $3 a ton, the cost of fuel would be reduced to $7.57 per horse-power per year, including heating, etc., and the total cost, to $15.77 per horse-power per year (3,080 hours in this case and a 1,200 h. p. plant).

Finally, none of these cases are in any respect an exceptional steam plant. And I should say that a modern compound engine plant of 1,000h. p. which, with coal at $3, costs $25.53 per year per horse-power, is sadly in need of overhauling. It is evident a good many people are not posted on what is being done in our textile mills, and without any great cry over it, either.

LEGAL NOTES

ELECTRIC HEATING LITIGATION.

WE would be glad to have you print the following in the next issue of The Electrical Engineer. The following states definitely the result of the recent decision in our favor by the United States Circuit Court of Appeals:

"The United States Circuit Court of Appeals for the Second Circuit, on Thursday, July 22, rendered an elaborate and sweeping decision, reversing the decree of the Circuit Court, which had granted to the Dewey Electric Heating Company an injunction against the Albany Railway Company, to prevent the use of the Consolidated Car Heating Company's temperature regulating switch in connection with an indicating device, as being an infringement of the ninth claim of the Dewey patent, No. 464,247. The court holds that this claim is entirely void for want of patentable invention, and this decision finally settles the right of the Consolidated Car Heating Company and its customers to use its temperature regulating switches with indicators as the same have been and are now constructed."

CONSOLIDATED CAR HEATING CO.,
FREDK. W. KELLEY, Assistant Treasurer.

THE CARBORUNDUM PATENTS SUSTAINED.

On Tuesday, July 27, Judge Buffington, in the United States District Court for the Western District of Pennsylvania, rendered a decision in the case of the Cowles Electric Smelting and Aluminum Company, of Lockport, vs. the Carborundum Company, of Niagara Falls. The decision was in favor of the Carborundum Company. The carborundum patents were obtained by Mr. E. G. Acheson, who is president of the Carborundum Company.

This case became celebrated not only in the United States, but in Europe, and had the decision been given in favor of the Cowles Company, it would have given them practical control of all metallurgical operations in which electric furnaces are used, as the Cowles Company claimed the original rights on all furnaces. The suit was first entered in 1894, and the argument before Justice Buffington was begun on December 7, 1896. Over 1,400 pages of expert testimony were taken in the case. It was the claim of Alfred H. Cowles that the electric furnace used was his discovery and that he had made carborundum in 1885. However, he did not himself know this until 1894, when specimens of carborundum were produced from the Boston museum. The suit asked for an injunction restraining the Carborundum Company from using the furnace.

The case of the defense was based on non-interference. In presenting the case to the court from which the decision has just been obtained, the defense was represented by George H. Christy and Thomas and Wm. Bakewell, while E. N. Dickerson, of New York, and C. M. Vorce, of Cleveland, represented the plaintiff.

There was great rejoicing at Niagara Falls when the import of the decision became known. The Carborundum Company was among the first enterprises to locate on the lands of the Niagara Falls Power Company, and their business grew so rapidly that the factory was very early enlarged. The business of the Monongahela City, Pa., plant was transferred to the Falls, and to-day the furnaces produce on an average 4,200 lbs. of carborundum per day. The business has spread to such an extent that plants have been established in Austria and Germany. Canada will have a plant within a year in all likelihood, while the Niagara Falls plant supplies the English and other foreign markets. No industry at Niagara Falls has prospered more than the Carborundum Company, and had the decision been against the company the effect would have been far reaching.

TROLLEY AND STEAM CROSSINGS

At Columbus, Ohio, on July 24, Railroad Commissioner Kayler made a decision that means much to the railroad interests and will no doubt establish a precedent in crossing disputes between electric and steam railroads. He holds that an electric road wanting to cross an established steam road must provide the necessary protection for itself and not interfere with the running of trains of the steam road in any way.

OBITUARY

HON. GEORGE S. HALE, of Boston, who died suddenly last week at his Bar Harbor cottage, was the father of Mr. R. S. Hale, the well known electrical and steam engineer, for whom deep regrets are felt at this heavy and serious loss.

NEWS AND NOTES

TESLA ELECTRIFIES THE EARTH.

According to the New York "Journal," of August 4, Mr. Tesla announces the completion of his work for the transmission of messages from one point to another on the earth, without the aid of wires. To give an idea of the high potential currents used in this work, he showed a large disc, from the center of which protruded a spherical electrode shooting forth long streams of ethereal flame. Mr. Tesla stated that the electrical disturbance thus created was felt throughout the globe. The article is graphically illustrated with a large picture of the contrivance for emitting the discharge.

THE STOCK MARKET

THE RISING TIDE.

THERE can be no question about the fact that right now, in the deep dullness of midsummer, a turn for the better has been made. It is signalized in many ways, and not least of all in the very early fall demand for staple merchandise of all kinds, especially out West, where current prices and large quantities of agricultural product have already created a most cheerful atmosphere. In manufactures, the settlement of the tariff has done much to improve things, and the increase in consumption creates a condition that is decidedly favorable. The figures of increase in the output of Bell telephones tell a remarkable story of better times, for the gain is made in the face of a severe competition and, therefore, counts double.

The stock market is responding to all these upward tendencies. Last week, of Western Union, there were sold 25,304 shares up to 86½, and of General Electric 27,987 shares up to 36⅛. On sales of 360 shares, American Bell was up to 228.

As to General Electric deferred dividends, "Rialto" has the following in the Boston "Advertiser:" New York hears that negotiations are well advanced toward settling with General Electric preferred stockholders for their accumulated dividends. When this is accomplished, it is said to be the intention of the managers to reduce the capitalization about 50 per cent., and put the new stock on a 6 per cent. dividend basis. A 6 per cent. manufacturing stock, it is claimed, would not be worth much more than 70, therefore the present price of General Electric at 35 is thought to represent about 70 for the new stock.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 20, 1897.

Alarms and Signals:—

ELECTRICAL GAS ALARM. J. Erikson, Providence, R. I., 586,813. Filed April 3, 1897.
Employs the heat of the gas flame to keep an electric circuit open that would otherwise be closed and sound an alarm if the stop-cock is open sufficiently to allow the escape of any gas.
ELECTRICAL SIGNALING APPARATUS. A. A. Andersen, Altoona, Pa., 586,891. Filed February 14, 1896.
For use with an arbitrary code.

Batteries Secondary:—

ACTIVE MATERIAL FOR SECONDARY BATTERY PLATES. S. A. Rosenthal, London, England, 586,627. Filed October 15, 1896.
Composed of oxid of lead, a rubber binding material soluble in the usual acid exciting agent and sulfate of ammonium.
CONNECTION FOR ELECTRIC SWITCHES. H. A. Bullard, Pittsfield, Mass., 586,543. Filed May 5, 1897.
Comprises a tapered plug, screw threaded at its extremity adapted to correspond with a nut carried in a recess in a block, connection being made through an annular groove opposite the recess.
FLEXIBLE INSULATED CONDUCTOR. J. H. Kelman, Pittsfield, Mass., 586,554. Filed November 27, 1896.
Consists of an extended length of electric conductor and a coating thereon of oxidized oil varnish such as linseed oil varnish.
CONNECTOR FOR ELECTRICAL CONDUCTING WIRES. S. P. Hull and J. DuBois, Albany, N. Y., 586,665. Filed November 25, 1896.
Consists of a plate of conductive material, and binding screws arranged at the opposite ends, each having a flat circumferential flange at the inner end of its head, the connector being arranged to swing freely with any swaying movement of the wires.
ELECTRIC LINE INSULATOR. J. J. Tracy, Hartford, Conn., 586,700. Filed May 27, 1897.
Comprises an insulator having a base, a bracket connected with the base, at one end by a pivot and at the other end by a lug, and an insulating cap connected with the bracket.
ELECTRICAL CONDUCTOR. C. N. Dutton, New York, 586,811. Filed July 27, 1896.
A multiple-wired electrical conductor, having its wires woven around a forked support adapted for use as a trolley wire for canal boat service.

Dynamos and Motors:—

ELECTROMAGNETIC MOTOR. F. J. Patten, New York, 586,823. Filed December 4, 1896.
For description see page 50, Electrical Engineer, July 22, 1897.
ELECTRIC MOTOR. F. A. Perret, Brooklyn, N. Y., 586,825. Filed March 27, 1897.
Comprises a driving wheel and stationary axle, an armature directly connected with the wheel, a cummutator support mounted directly on the armature, a field magnet mounted directly upon the stationary axle, and a brush support mounted directly on the field-magnet.

Electro-Therapeutics:—

INDUCTION COIL FOR MEDICAL APPARATUS. H. C. Porter, Chicago, Ill., 586,622. Filed January 26, 1895.
Means whereby in one apparatus either a high tension or low tension current may be employed and regulated as desired.
COMBINED SYRINGE AND ELECTRICAL APPARATUS. L. G. Woolley, Grand Rapids, Mich., 586,679. Filed December 7, 1896.
An electrical apparatus having a normally open circuit adapted to be closed by a syringe acting as a weight and closing the circuit by the weight of the liquid in the bag, and permitting the circuit to open as the liquid escapes.

Measurement:-

ELECTRICAL METER. W. D. Marks, Philadelphia, Pa., 586,559. Filed January 23, 1897.
Combines with the actuating coils and the movable member means for eliminating or reducing magnetic lag.
ELECTRIC METER. W. D. Marks and G. R. Green, Philadelphia, Pa., 586,560. Filed May 20, 1897.
Comprises an oscillating motor, a brake carried by a stationary support and engaging periodically with a movable member of the motor.
EXCESSIVE CURRENT RECORDER. J. R. Cravath, Chicago, Ill., 586,723. Filed February 5, 1897.
Adapted for use on motor cars.

Miscellaneous:—

CIRCUIT CONTROLLER FOR ELECTRIC VEHICLES. K. Knudsen, Chicago, Ill., 586,606. Filed October 21, 1896.
ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 586,615. Filed August 14, 1895.
A supporting frame carrying at its upper and lower edges insulating blocks, a continuous coil arranged in zigzag fashion about the insulating blocks in such manner that the coils converge from top to bottom and vice-versa.
AMALGAM WASHING APPARATUS. H. C. F. Stormer, Christiania, Norway, 586,635. Filed February 6, 1897.
Consists in subjecting streams of amalgam in tubulous form to the action of a dissolving liquid.
PURIFYING WATER BY ALTERNATING ELECTRIC CURRENTS. E. Verstraete, St. Louis, Mo., 586,643. Filed June 16, 1896.
Comprises a settling basin adapted to contain liquid, electrodes therein, a source of alternating currents, a plurality of tension reducing devices, and switches in the working circuits whereby the tension of the current supplied to the electrodes may be changed.
ELECTRIC FURNACE. R. F. S. Heath, Camden, N. J., 586,686. Filed February 24, 1896.
A furnace for the manufacture of carbid of calcium, employing adjustable carbon electrodes and a revolving melting pot.
ELECTRIC FURNACE. R. F. S. Heath, Camden, N. J., 586,687. Filed February 21, 1896.
Employs electrodes adapted to be rotated around the melting chamber for the manufacture of carbid of calcium.
METHOD OF AND APPARATUS FOR EFFECTING ELECTROLYSIS. C. Kellner, Vienna, Austria-Hungary, 586,729. Filed February 24, 1896.
Consists in passing an electric current through a solution of a salt, to a mercury cathode flowing uninterruptedly from a higher to a lower level and before reaching the lower level flowing alternately and repeatedly out of contact with the salt solution into contact with an agent capable of decomposing the compound formed.
TROLLEY POLE. C. N. Dutton, New York, 586,809. Filed July 27, 1896.
Adapted for use on canal boats.
ELECTRIC FURNACE. F. J. Patten, New York, 586,822. Filed September 14, 1896.
Comprises a furnace wall, a pair of carbon electrodes inclosed within the wall, one of the electrodes being circular in cross-section, means for rotating the arc between and relatively to the electrodes and passage, arranged to convey material through the annular arcing space traversed by the rotating arc.
ELECTRIC FURNACE. F. J. Patten, New York, 586,824. Filed January 30, 1897.
Consists in passing an electric current through a mass of material of low and uniform conductivity, establishing around it a magnetic field, having its lines of force transverse to the line of current flow through the mass, and causing the field to rotate about the line of current flow.
ELECTRICALLY OPERATED VALVE. F. McDonald, Portland, Me., 856,861. Filed April 22, 1897.
Mechanism for controlling the flow of water through a fire hose.
ELECTRODEPOSITING DEVICE. J. Bossard, Dubuque, Iowa. 586,894. Filed May 31, 1895.
Consists of a tank, with anode connection, a circular carrier having cathode connections from which a number of articles to be deposited upon are suspended within the bath and are caused to rotate in a horizontal plane.
MAGNETO SPINDLE. A. Gartner, Paterson, N. J., 586,790. Filed May 3, 1897.
Comprises a base in which is mounted a sleeve-whirl spindle, driving means for operating spindle, and a magnet carried by the base and in close proximity with that portion of the sleeve-whirl which is in engagement with the driving means.

Railways and Appliances:—

TROLLEY GUARD. J. M. Kirker, Louisville, Ky., 586,556. Filed August 28, 1895.
Comprises an eccentrically mounted wire catching and restoring wheel positioned alongside of the trolley-wheel.
CONDUIT ELECTRIC RAILWAY. W. E. M. Jackson, Indianapolis, Ind., 586,602. Filed October 5, 1894.
Consists of an insulator comprising a non-conductive compressible open spiral, a containing cup, a cover and a standard on which the cup and cover are adjustable.
TROLLEY. W. Willett, Johnstown, Pa., 586,647. Filed March 22, 1897.
Employs two trolley wheels arranged at obtuse angles to the pole and adapted to embrace and ride upon the upper side of the trolley wire.
APPARATUS FOR WORKING ELECTRIC TRAMWAYS. C. Anderson, Leeds, England, 586,652. Filed February 13, 1896.
Employs a haulage cable for use as an auxiliary power actuated by an electric motor.
DASH ELECTRIC HEADLIGHT. J. Kirby, Jr., Dayton, Ohio, 586,774. Filed January 8, 1897.
An electric headlight having the open end of its case secured to the rear side of the dashboard, and means whereby the lamp may be adjusted to locate it in proper relation to the reflector.
ELECTROMAGNETIC THIRD RAIL SYSTEM. W. Grunow, Jr., Bridgeport, Conn., 586,845. Filed August 26, 1896.
An electrical contact system, consisting of a free reciprocating electromagnetic contact, operated by the alternate action of a separate electromagnet and gravitation.
UNDERGROUND SYSTEM FOR ELECTRIC RAILWAYS. A. S. Krotz, Springfield, Ohio, and W. P. Allen, Chicago, Ill., 586,852. Filed February 12, 1897.
Comprises a feeding conductor and a contacting rail, a support common to both, an insulator to which the support is attached, and a shield on the support and between the insulator and the contacting rail.
ELECTRIC RAILWAY SYSTEM. H. P. Wellman, Ashland, Ky., 586,920. Filed December 12, 1896.
A sectional conduit system employing a short circuiting switch comprising an electromagnet having its yoke removed, and means carried by the motor car for engaging the electromagnet and temporarily supplying the yoke.
ELECTRICALLY OPERATED RAILWAY BARRIER. C. C. Van der Vale, Haarlem, Netherlands, 586,578. Filed September 10, 1896.
Details of construction.
HEADLIGHT. C. Bash, Boston, Mass., 586,584. Filed November 9, 1895.
An electric headlight embodying an oil lamp for emergency use.
AIR CAR. A. Brodbeck, Chicago, Ill., 586,590. Filed August 26, 1896.
An aerial railway comprising an electric elevated rail, a balloon, a trolley carriage mounted on the rail, rods connecting the balloon and carriage, a car suspended from the balloon, electric propelling mechanism carried by the car, and an auxiliary electric rail and a pivoted trolley contacting with the auxiliary rail and carried by the trolley carriage.
ELECTRICALLY ACTUATED SWITCH MECHANISM. W. S. Browne, Brooklyn, N. Y., 586,702. Filed November 25, 1896.
An automatic switch for electric railways.

Switches, Cut-Outs, Etc.:—

FUSIBLE CUT-OUT. C. G. Perkins and J. Tregoning, Hartford, Conn., 586,565. Filed December 15, 1896.
Details of construction.
LIGHTNING ARRESTER FOR SWITCHBOARDS. A. M. Taylor, Niles, Mich., 586,575. Filed March 8, 1897.
Of the magnetic type. Details of construction.
RHEOSTAT. O. H. and A. F. Pieper, Rochester, N. Y., 586,864. Filed March 23, 1897.

Adapted for use in connection with a cataphoric apparatus used in dental operation.

ELECTRIC SWITCH. J. F. McElroy, Albany, N. Y., 586,933. Filed January 9, 1896.

The combination of an electric snap switch and an adjusting switch, whereby the adjusting switch is opened or closed by the snap switch.

Telegraphs:—

TELEGRAPH CABLE. J. M. Barr, London, England, 586,755. Filed December 26, 1896.

Comprises a pair of parallel adjacent conductors connected at one end to a common return, a source of current having one pole connected to the common return, contacts connected to the conductors at the transmitting end, and a key connected to the other pole of the source between the contacts.

Telephones:—

TELEPHONE ATTACHMENT. W. W. Beck, Sebastopol, Cal., 586,539. Filed March 5, 1897.

A holder adapted to support the telephone receiver in close proximity to the ear of the user.

TELEPHONE SWITCHBOARD. H. V. Hayes, Cambridge, Mass., 586,685. Filed January 29, 1897.

Means whereby all answered calls at the central station are recorded.

PENDENT MICROTELEPHONE. F. Muller, Berlin, Germany, 586,699. Filed December 12, 1896.

Details of construction.

TELEPHONE ATTACHMENT. S. C. Houghton, San Francisco, Cal., 586,793. Filed June 15, 1897.

A support for a telephone receiver movable laterally in two directions and having a swiveled section for supporting and reversing the receiver.

TELEPHONE SIGNALING RELAY AND CIRCUIT. A. S. Williams, Newton, Mass., 586,888. Filed May 20, 1897.

System of signaling the central station in which glow lamps are employed as line signals, one for each line, and in which a supplementary signal is associated with a series of such line lamps and made common to the series.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 27, 1897.

Alarms and Signals:—

ELECTRIC BELL. J. T. O'Brien, Bridgeport, Conn., 587,062. Filed April 13, 1897.

The ringing is accomplished by the opening and closing of a shunt circuit.

Conductors, Conduits and Insulators:—

CONDUIT. A. S. Krotz, Springfield, O.; W. P. Allen, Chicago, Ill., and O. S. Kelly, Springfield, O., 587,213. Filed May 28, 1896.

Provides an insulated shield for the conductor rail in "third-rail" system.

WIRE HOLDER. J. B. Lawrence, Salem, N. J., 587,216. Filed November 2, 1896.

Consists of an upright standard having feet provided with openings, upwardly projecting arms having interior screw threads, and an exteriorly-screw threaded insulator.

INSULATOR. H. Rudolf, Berlin, Germany, 587,273. Filed October 14, 1896.

Consists of a body portion having a head in which is formed a deep transverse groove in the bottom of which is a cavity adapted to receive a bend in the wire, the head being also provided with a transverse perforation which passes through the cavity, and a locking bolt which passes through the perforation, and holds the wire in place.

Dynamos and Motors:—

BRUSH HOLDER. N. M. Beede, Schenectady, N. Y., 586,957. Filed May 5, 1897.

Comprises an opening for the reception of a commutator brush, a brush movable in the opening, a flexible connection leading from the brush and a spring clamp secured to the flexible connection, and making an electrical connection, with the body of the brush holder.

FORM FOR WINDING COILS FOR DYNAMO ELECTRIC MACHINES. H. Geisenhoner, Schenectady, N. Y., 586,995. Filed March 16, 1897.

Means for giving the coil a shape while winding that is substantially the same as that of the finished article.

MULTIPOLAR DYNAMO ELECTRIC MACHINE. S. W. Rushmore, Brooklyn, N. Y., 587,163. Filed February 23, 1897.

For description see page 36, July 15, 1897.

DYNAMO ELECTRIC MACHINE. S. W. Rushmore, Brooklyn, N. Y., 587,164. Filed May 14, 1897.

For description see page 36, July 15, 1897.

Lamps and Appurtenances:—

ELECTRIC ARC LIGHT REFLECTOR. Chas. M. Bolles, Dallas, Tex., 586,986. Filed July 13, 1896.

Details of construction.

ADJUSTABLE LIGHT. F. A. Lavercomte, St. Louis, Mo., 587,151. Filed March 8, 1897.

Comprises an adjustable support capable of lateral movement upon a vertical support.

Measurements:—

RECORDING SPEED INDICATOR. Edward P. Decker, Brooklyn, N. Y., 586,961. Filed April 7, 1897.

The indicator mechanism is driven by an electric motor.

ELECTRIC METER. G. F. Packard, Fort Wayne, Ind., 587,015. Filed May 6, 1897.

Details of construction.

Miscellaneous:—

ELECTRICALLY OPERATED LOCKING DEVICE FOR ELEVATORS. T. W. Jenkins, Philadelphia, Pa., 587,002. Filed October 2, 1895.

Comprises a car with a power-controlling device and a door, a lock for the wheel, a magnet in an electric circuit controlling the lock and contact points connected by the action of the door.

ELECTRIC CONDENSER. C. S. Bradley, Avon, N. Y., 587,114. Filed October 7, 1895.

A condenser having its pile of plates inclosed in a fluid and air-tight metallic casing hermetically sealed at all points.

PROCESS OF AND APPARATUS FOR MANUFACTURING METALLIC CARBIDS. I. L. Roberts, Niagara Falls, N. Y., 587,138. Filed December 29, 1896.

Employs a continuous horizontal mechanical conveyor, two electrodes located in proximity thereto, and means for feeding a mass of material to be treated into the conveyor above and below the electrodes.

ELECTRIC PROGRAM-CLOCK. Ernest Bobsien and S. L. Prager, Mt. Vernon, N. Y., 587,143. Filed February 8, 1897.

Details of construction.

ELECTRIC FURNACE. G. De Chalmot, Leaksville, N. C., 587,182. Filed February 27, 1896.

Comprises a carbon pencil, a crucible into which the pencil may enter, and independent mechanism for agitating the crucible in order to shake down the granular material fed into it.

APPARATUS FOR TREATING DISEASES. H. Sanche, New Orleans, La., 587,237. Filed October 27, 1887.

An electric treatment involving difference of temperature in the positive and negative element.

Railways and Appliances:—

TROLLEY WHEEL FORK. S. B. Thompson, Baltimore, Md., 587,047. Filed December 2, 1896.

One of the supports of the trolley axle is formed of a flat spring the upper end of which presses against the hub of the trolley-wheel forming an electrical contact, and its lower end is rigidly secured to the base of the fork.

CAR STEP. Albert Blum, Cincinnati, Ohio, 587,073. Filed August 3, 1896.

Consists of a movable step operated by an electro-magnet.

RAIL BOND. J. A. Mosher, Chicago, Ill., 587,134. Filed June 21, 1897.

Comprises a flexible body portion provided with solid ends having riveting studs adapted to pass through the web of a rail.

TROLLEY. A. S. Krotz, Springfield, O.; W. P. Allen, Chicago, Ill., and O. S. Kelly, Springfield, O., 587,214. Filed June 16, 1896.

Consists of a base, one or more flat spring supports, a contact shoe attached to the free end of the spring supports, a conductor strip of high conductivity connecting the contact shoe and base, and a stop.

Regulation:—

RECTIFIER. E. Thomson, Swampscott, Mass., 586,024. Filed October 31, 1896.

Means for rectifying alternating current, which consists in passing the current through a rectifying device and by external power imparting to the rectifier a tendency to rotate at a speed greater than synchronism.

Switches, Cut-Outs, Etc.

LAMP SOCKET. H. C. Wirt, Schenectady, N. Y., 587,027. Filed April 30, 1897.

A two-part shell, one part of which is provided with L-shaped open slots, and the other with screws projecting through the L-shaped slots; in combination with a molded base having enlarged recesses into which the ends of the screws project and have play to lock the parts together.

FUSE HOLDER AND ELECTRIC CUT-OUT. H. A. Lewis, Norristown, Pa., 587,217. Filed January 11, 1897.

Is provided with a circuit breaker interposed in the line-wire, and a thermostat comprising a tube fixed at one end, and a line wire passing through the tube to heat the same, and intermediate mechanism for connecting the tube with the circuit-breaker.

CIRCUIT CLOSER. S. C. Houghton, San Francisco, Cal., 587,260. Filed May 14, 1897.

Details of construction.

Telegraphs:—

TELAUTOGRAPH. L. O. McPherson, Highland Park, Ill., 587,013. Filed October 9, 1895.

Comprises means for transmitting pulsations of successively alternate polarity to drive a receiving pen, a reversing relay operated by changes in the strength of the pulsations and a circuit controlled by the rapidity of the succession of the pulsations for preventing false operation of the reversing relay.

Telephones:—

TELEPHONE SYSTEM. G. Dillberg and P. Rabbidge, Sydney, N. S. W., 586,993. Filed September 9, 1895.

Comprises a speaking circuit, a call circuit, and induction coil having its primary and secondary coils in series in the speaking circuit and an armature controlled by the induction coil to control the call-circuit.

TELEPHONE EXCHANGE. M. G. Kellogg, Chicago, Ill., 587,004. Filed July 26, 1890.

The switchboard is divided into a calling and an answering section and circuits are provided for connecting the lines on the two different boards.

CALLING APPLIANCE FOR TELEPHONE SWITCHBOARDS. F. R. McBerty, Downer's Grove, Ill., 587,080. Filed November 12, 1895.

Embodies apparatus for transmitting selective signals in "party" telephone lines.

TELEPHONE EXCHANGE APPARATUS. F. R. McBerty, Downer's Grove, Ill., 587,081. Filed June 3, 1896.

Consists in interposing in the ground branches of the lines a number of polarization-cells sufficient to counteract any difference of potential on the line.

TELEPHONY. J. W. Gibboney, Lynn, Mass., 587,119. Filed July 26, 1895.

Syetem adapted to utilize alternating current.

TELEPHONY. J. W. Gibboney, Lynn, Mass., 587,120. Filed August 3, 1896.

Similar to above.

SWITCHBOARD ANNUNCIATOR. N. H. Holland, Montreal, Canada, 587,204. Filed September 5, 1896.

Details of construction.

TELEPHONE TRUNK CIRCUIT. J. J. O'Connell, Chicago, Ill., 587,226. Filed February 11, 1897.

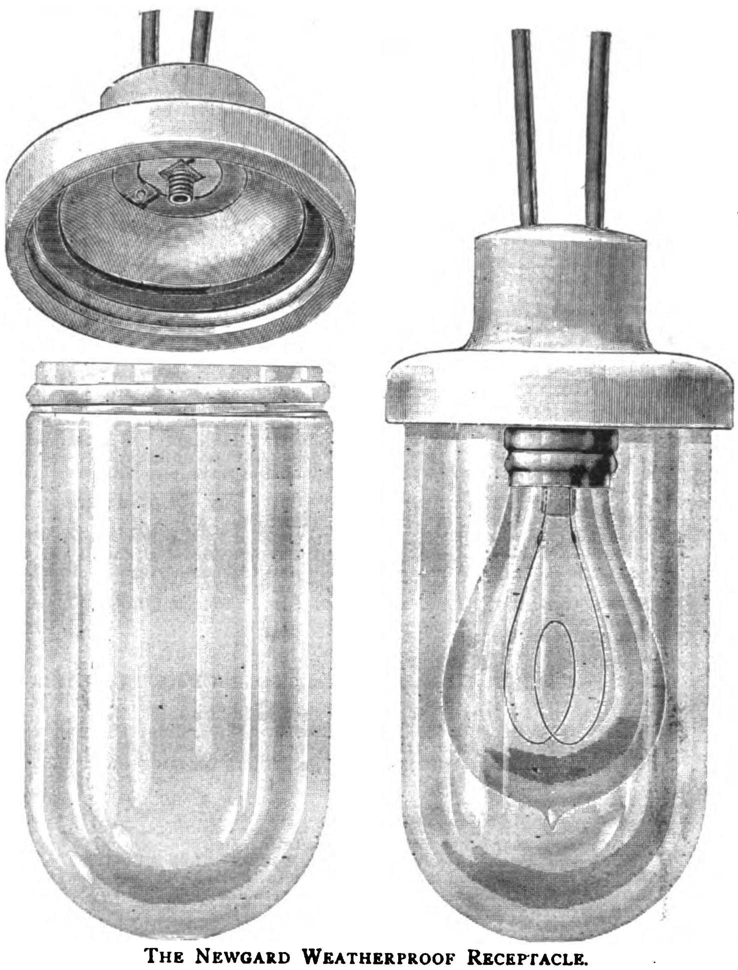
Means whereby the operators at both ends are enabled to display call and disconnecting signals at the key board of the other.

TRADE NOTES & NOVELTIES

THE NEWGARD WATER PROOF RECEPTACLE.

THIS is a combination of waterproof socket and waterproof globe complete in one appliance. As will be seen from the accompanying illustration, a single piece of porcelain forms a socket or receptacle for the lamp, and the cover for the globe. The conducting wires are permanently sealed in this porcelain cap, which is threaded into the receptacle, and the glass globe and rubber gasket in the cover makes a watertight fitting between the cover and the globe, making an outfit which can be used under water with perfect safety.

The Newgard waterproof receptacle finds its largest field of usefulness in breweries, packing houses and similar work where it is customary to wash the floors, walls and ceilings



THE NEWGARD WEATHERPROOF RECEPTACLE.

with showers of water. It is also said to be a perfect solution of the difficulty in all places where severe conditions have heretofore made a perfect insulation of lamp and socket an impossibility, such as cold storage warehouses, paper mills, etc.

The receptacle is made regularly with T.-H. base, but can be used with Edison lamp by use of a T.-H. adapter. The globe will take either a 16 or 32 c. p. lamp, the opening in the globe being 2¾ inches. The length of the globe is 6 inches, while 7 inches is the length of the outfit over all.

Although just introduced, several hundred of these outfits have already been placed in a number of Chicago breweries, and the results secured have been most satisfactory. The Newgard waterproof receptacle promises to come into very extensive use. The Electric Appliance Company, of Chicago, will be glad to give further information on this specialty.

THE VULCAN FOUNDRY.

With regard to the new Vulcan Foundry at Pawtucket, R. I., in which Mr. Gardiner C. Sims is interested, it is stated that the intention is to operate the plant throughout by electric motors, for which current will be supplied from the central station of the Pawtucket Electric Company. Other features of economy and convenience will abound.

BELL TELEPHONE OUTPUT.

The instrument statement of the American Bell Telephone Company for the month ended July 20 shows the net number of instruments put into lessors' hands as 8,618 against 9,588 the previous month, and 12,146 the month previous to that. The gross output for the month shows an increase of 2,975 instruments over last year, while the number of returns was 3,249 less, leaving a net gain of 6,524. For seven months 1,100 more instruments have been put out than last year, but these are increased to 2,920 by 1,820 less returns. The comparative instrument figures follow:

Month July 20.	1897.	1896.	1895.
Shipments	15,859	12,584	13,837
Returned	7,241	10,490	7,513
Net output	8,618	2,094	6,324
Since Dec. 20.	**1896-7.**	**1895-6.**	**1894-5.**
Shipments	127,778	126,678	98,896
Returned	51,847	53,667	47,121
Net output	75,931	73,011	51,775
Instruments in use	848,558	747,987	634,281

ELECTRICAL APPARATUS WANTED IN BRITISH HONDURAS.

The United States Consul at Belize, British Honduras, reports that the Municipal Board of Belize is contemplating the erection of an electric light plant for lighting the streets and public buildings of the city. He expresses the belief that there is an opportunity for American electrical manufacturers to install this plant. A telegraph line of about 200 miles in length is also to be constructed in the Belize consular district, and it is quite likely that a telephone line will be used in conjunction with it.

ADVERTISERS' HINTS

THE POTOMAC TERRA COTTA COMPANY, 36 Corcoran Building, Washington, D. C., advertise the Mason conduit for underground electrical subways. These conduits were described in our issue of July 29.

M. R. RODRIGUEZ, 19 Whipple street, Brooklyn, N. Y., calls attention to the fact that the "Premier Products" are not new on the market and the "Premier" motors, at $1.50 and upward, are guaranteed.

THE CENTRAL ELECTRIC COMPANY, 173-175 Adams street, Chicago, suggest to those participating in the return to prosperity to bear in mind that they are able to take care of orders at all times.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, note the advantages of the Newgard waterproof receptacle, combining a waterproof globe and socket. The fitting between globe and cover is made waterproof by a rubber gasket, making an excellent outfit for packing houses, breweries, etc.

KEUFFEL & ESSER COMPANY, 127 Fulton street, New York, supply everything required for blue-printing, drawing materials and instruments, surveying instruments, etc.

W. F. & JOHN BARNES CO., 281 Ruby street, Rockford, Ill., are making a special offer in lathes, which is well worthy of investigation by those interested.

STANLEY & PATTERSON, 32-34 Frankfort street, New York, have just issued one of the most complete catalogues of electric bell, battery and telephone and telegraph supplies which has come to our notice. They will take pleasure mailing one to any address upon application.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., say that for tin or shingle roofs and iron work, their graphite paint is absolutely without an equal. Tin roofs well painted with it have not required repainting for ten to fifteen years. They issue a circular regarding their paints which may be had for the asking.

NEW ENGLAND NOTES

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., write as follows: "Our business is starting in well and there is prospect of large trade this fall. People are realizing that our lamp at 12 cents is in every way as good as the new lamp at combine prices. For the last few days we have averaged a little over 3,000, and orders are increasing."

THE UNITED GAS IMPROVEMENT COMPANY, of Philadelphia, are erecting at Atlanta, Ga., a water tower and tank. The tank has a capacity of 10,000 gallons, and is supported on a tower 60 feet high. They have let the contract for furnishing and erecting the tank and tower to the Berlin Iron Bridge Company, of East Berlin, Conn.

LAUNDRY IRONS.—Recent installations of complete outfits of electric laundry irons by the American Electric Heating Corporation, of Boston, are the Parker House and Young's Hotel, Boston; Milwaukee Hospital for Insane, Wawatosa, Wis.; Michigan Asylum, Milwaukee, Wis.

NEW YORK NOTES.

THE UNITED STATES ELECTRICAL SUPPLY COMPANY has been incorporated under the laws of the State of New York, with a capital stock of $10,000. The company have located at 120 Liberty street, with Mr. W. J. Clarke, formerly with the Adams-Bagnall Electric Company, as general manager. They are prepared to take contracts for the installation of all kinds of electrical plants, but are at present making a specialty of the W. J. C. arc and incandescent lamps, magnet spools for arc lamps, and a very complete line of X-ray apparatus and accessories.

THE ELECTRIC ARC LIGHT COMPANY, of 687 Broadway, New York, manufacturers of the "Pioneer" 150-hour enclosed arc lamp, continue to report booking satisfactory orders. A recent very large order is for the installation at the Seventh Regiment Armory, of New York City. This contract was awarded after a very severe test, the "Pioneer" coming off victorious.

KEASBEY'S MAGNESIA, furnished by Robert A. Keasbey, 54 Warren street, New York City, is the pipe and boiler covering used in the plant of the Union Traction Company, at Rutherford, N. J. This is but another addition to the long list of lighting or railway plants where this admirable specialty is to be found.

CHERRY ELECTRIC WORKS, 25-27 Third avenue, New York, have just issued a very neat catalogue and price list of their voltmeters, ammeters, fan motors and a number of other specialties of their manufacture. The reasonable prices at which these goods are offered will well repay interested parties to write to the Cherry Electric Company for their catalogue, which will be cheerfully mailed on application.

ONE OF THE most complete catalogues ever issued to the trade is that of Stanley & Patterson, 32 Frankfort street, New York, just out. It is the ninth edition of their electric light supply catalogue and contains 272 pages describing and giving prices on over 3,000 different articles used in electric lighting plants, most of which are illustrated. The firm will send the book gratis to any one upon application and receipt of business card.

"BUSY LINES" is the title of an interesting new circular just issued by the New Telephone Company, suggesting a "double track" system where one line is not enough, and showing how cheaply it can be carried out, even to the extent of a private branch exchange in one's office.

A CABLE ADDRESS DIRECTORY is being got up by a number of the officials connected with the Commercial and Postal Companies, among them Messrs. Bruch, Clapperton, Beck and Cuyler. This useful compilation will be a book of 600 pages, of which 100,000 copies will be printed. Names will be inserted by subscription only. The company's address is the Postal Telegraph Building, New York City.

STILES & FLADD PRESS COMPANY, of Watertown, N. Y., have just issued a very neat and handsome catalogue of their presses, drop hammers, dies, etc. It is well put together, neatly illustrated and full of useful information. As representing the growth of one year's business in this line, the catalogue is remarkable, as the first machine was shipped about May, 1896. A variety of small apparatus is included in the catalogue, which appeals to many classes of buyers.

LE VALLEY VITÆ CARBON BRUSH COMPANY, of New York City, has been formed, with a capital stock of $25,000, to make and sell an improved commutator brush and other electrical devices. The directors are D. A. Le Valley and J. V. Clarke, White Plains, N. Y.; E. J. Lewis, J. R. Hurnett and W. J. Creed, of New York City.

SNOW STEAM PUMP WORKS, of Buffalo, manufacturers of steam pumps, pumping engines and hydraulic machinery, have issued a useful catalogue of their 1897 styles of apparatus in that line. It is oblong,113 pages, and illustrates a large number of pumps of all sizes and styles for a very wide range of work.

PHILADELPHIA NOTES

W. H. WESTON & CO., 1303-9 Buttonwood street, Philadelphia, have just issued their illustrated catalogue, No. 5. It is an admirable exposition of their very fine work, and shows a wide range of apparatus for lighting and power switchboards, complete systems of stage regulating apparatus, and special appliances requiring skill in design and combination. Some of the devices illustrated have already received attention in these pages. This handsome pamphlet contains also a variety of useful data rendering it valuable as a book of reference.

WESTERN PENNA. TELEPHONE ASSOCIATION, at a recent meeting, decided not to join the National Independent Association at present. A committee, consisting of J. W. Jameson, of Newcastle; W. D. Watson, of Indiana, and A. W. Dively, was appointed to consider the construction of connecting toll lines.

READ-MORRILL ELECTRIC COMPANY has been formed in Philadelphia, with a capital stock of $10,000, by C. L. Reed, M. T. Morrill, J. W. Laws, H. C. Harmon and H. A. Harmon.

THE STERLING VARNISH COMPANY, of Pittsburg, Pa., have recently ordered a 75 h. p. Ball automatic engine for electrical purposes from the Ball Engine Company, Erie, Pa.

BALL ENGINES.—The Chesapeake & Ohio Railroad has ordered through Crook, Horner & Company, the Baltimore representatives of the Ball Engine Company, Erie, Pa., two Ball engines for electrical purposes. One of these engines is direct connected to a generator. The engines will be used at Newport News, Va.

WESTERN NOTES

FOSTORIA, O.—The capital of the new Crouse-Tremaine Incandescent Lamp Company is $50,000, all paid up. The factory will shortly be started with a capacity of 5,000 lamps per day. The officers are as follows: J. B. Crouse, president; R. Crocker, vice-president; H. A. Tremaine, secretary and treasurer. These are directors, with Ira Cadwalader and B. G. Tremaine, of Cleveland, O.

PACIFIC ELECTRIC COMPANY, La Crosse, Wis., have secured possession of a clever device called "the electrical trick," by which a piece of money can be made to disappear in the most mysterious manner, so that a very clever person would fail to detect how the illusion is accomplished. The company use it to advertise their shade lamps and dental lamps, and will be pleased to send it to any one who will write for same and will enclose four cents to cover cost of mailing.

UNION STORAGE BATTERY COMPANY.—Articles of incorporation of the Union Storage Battery Company, of Cleveland, have been filed with the Ohio Secretary of State. The capital stock is $10,000, and the incorporators are F. C. Phillips, G. A. Ford and G. N. Surridge, all of Cleveland. Mr. Phillips is well known as the general manager of the Elwell-Parker Electric Company. Mr. Ford has done a great deal of useful work in the storage battery field.

NATIONAL AUTOMATIC TELEPHONE COMPANY has been formed at Salina, Kan., to make telephones and switchboards of the Lundquist type. The officers are: W. W. Watson, president; F. A. Lundquist, vice-president; J. Anderson, secretary, and E. W. Ober, treasurer. The system is already in use at Sterling, Kan., and several other towns propose to put it in. The capital stock is $100,000. The factory will be at Salina.

UNION IRON WORKS, of San Francisco, are reported to have placed an order for $142,000 worth of Chloride accumulators.

SMYTH ELECTRIC COMPANY has been formed at Pasadena, Cal., with a capital stock of over $300,000. The directors are G. F. Kernaghan, B. F. Ball, H. M. Dobbing, R. Eason, D. M. Smyth, J. E. Smythe and A. R. Metcalfe.

THE OHIO ELECTRIC WORKS, of Cleveland, Ohio, has been purchased by A. C. Fletcher, who has been the company's president and largest stockholder. The plant is to be enlarged but the business will be continued on about the same lines with the exception that about September 1 a table lamp will be added to the line. This lamp will be illuminated by a primary battery similar to that used in the bicycle lamp manufactured by the company.

RICE MACHINERY COMPANY, of 166-174 South Clinton street, Chicago, have issued an excellent book devoted to their power transmitting appliances, elevating and conveying machinery, of all classes. It runs a length of nearly 300 pages, and is most profusely illustrated, the data given being also most complete and exhaustive, so that central stations, electric roads, isolated plants, electrically equipped factories, and other places where power appliances are in use, can order intelligently and safely from the catalogue alone. The Rice Company are general agents for the celebrated Dodge Independence wood-split pulleys and other Dodge specialties.

BROWNLEE & CO., of Detroit, Mich., the well known manufacturers of cross-arms, oak insulator pins and wooden trolley poles, write: "The circulation of The Electrical Engineer seems like Puck's girdle, to go 'round the earth.' We have just received an inquiry, with mention of your paper, from Liege, Belgium."

GALION, O.—The Electric Signal Clock Company has been formed with a capital stock of $25,000.

THE OHIO TELEPHONE CONSTRUCTION COMPANY is is the new corporate title just adopted by the former Ohio Harrison Telephone Construction Company, of Norwalk, O.

JAMES LEFFEL & CO., Springfield, Ohio, have issued a neat, new pamphlet, "D," replete with numerous illustrations and descriptions of the throttling and automatic engines, with portable and stationary boilers, which they are building in a variety of sizes and styles. Copy is sent free to parties interested, on application to the company.

THE ELECTRICAL HOUSE goods department in the electrical supply business has been more or less neglected during the past few years, owing, largely, to the prominence taken by the electric light and power department of the same business. The Electric Appliance Company pride themselves upon the fact that the electrical house goods department of their business has always had good attention, and particularly during the past six or twelve months. The house goods department in the new issue of their general catalogue is to be exceedingly complete, and the company claim that they will list the most complete line of house goods ever catalogued.

DUBUQUE, IA.—The Inter-State Telephone and Electric Company has filed articles of incorporation. The new company is incorporated, with a capital stock of $100,000, for the purpose of constructing a plant for the Dubuque Telephone Company and building also toll lines into the city. The officers of the corporation are F. F. Sapp, of Chicago, president; E. T. Keim, of Chicago, secretary, and R. W. Stewart, of Dubuque, attorney. The general business of the company is to be the constructing, acquiring, operating, buying and selling of telephone exchanges, instruments, etc. Mr. Sapp, who is the president of the company, is a wealthy Chicago capitalist.

MR. W. D. MYERS, manager for thte Union Telephone Company at Peoria, Ill., has joined the company's engineering force at Chicago and has been succeeded by Mr. E. J. Garland, of Springfield, Ill.

ST. LOUIS, MO.—The plans for the exchange switchboard, etc., of the Kinloch Telephone Company have been furnished by Mr. Milo G. Kellogg, of Chicago, who is also building the board.

MR. M. M. WOOD, who has been for some time past associated with the Ohio Brass Company, Mansfield, Ohio, has accepted the position of electrical engineer to the Central Union Brass Company, St. Louis, Mo. Mr. Wood is the inventor of Wood's railway material, and now has a complete line of overhead specialties, which the Central Union Company will shortly bring out, and which are not in any way affected by existing patents. The company will also manufacture and sell the well known "Type W" material and push hard for a good share of the trade among electric railways. Mr. Wood has the best wishes of his many friends for success in his new position.

J. HOLT GATES, Western agent of the Walker Company, has removed his offices to suite 1323 and 1324 Marquette Building, where he has much larger quarters. Mr. Gates also reports that he has taken the Western agency of the Wagner Electric Manufacturing Company's alternating current transformers, single-phase alternating current motors, alternating current instruments, switches, etc. Mr. Gates has also taken the Western agency of the Card Electric Company, of Mansfield. Ohio.

SOUTHERN NOTES

W. B. UPTON & CO. have opened an office in the Washington Loan and Trust Building, Washington, D. C., for the purpose of conducting a general engineering and contracting business, electric and hydraulic plants being a specialty. Mr. Upton is known in connection with several large installations.

BALTIMORE, MD.—The Baltimore & Ohio Railroad has just completed on Henderson's Wharf a six-story tobacco warehouse which has more floor space than any other building in the city. It cost about $150,000, is equipped with all modern machinery for handling tobacco and has four electric elevators. The building is fireproof and electric lighted.

THE MT. WASHINGTON ELECTRIC LIGHT AND POWER COMPANY, Mt. Washington, Md., have recently increased the capacity of their station by adding a 100 h. p. engine, built by the Ball Engine Company, Erie, Pa., being the third engine of this manufacture now in this station.

THE MT. VERNON COMPANY, Woodberry, Md., have recently purchased from the Ball Engine Company, Erie, Pa., a 100 h. p. Ball automatic engine, being the second order for this make of engine.

CROWLEY, LA., is to spend $30,000 on municipal waterworks and electric lighting plant.

MISCELLANEOUS

THE ELECTRIC FURNACE.—I.

BY LIEUT. F. JARVIS PATTEN.

THE highest terrestrial temperature known to science, about 6,000 degs. F., is that required to fuse and volatilize carbon, and is only found in the electric arc. It is not at all surprising therefore that soon after the electric arc became a manageable thing its application to heating and fusion were thought of, hence the electric furnace. In fact, down to the present time, although this application is nearly twenty years old, the most advanced forms of electric arc furnace in use are little more than simple mechanical contrivances for maintaining a very powerful arc between electrodes and other ordinary contrivances for getting the material to be treated into the arcing space and keeping it there.

To-day the furnace is the least developed invention in the electric arts, although it doubtless has a great future and

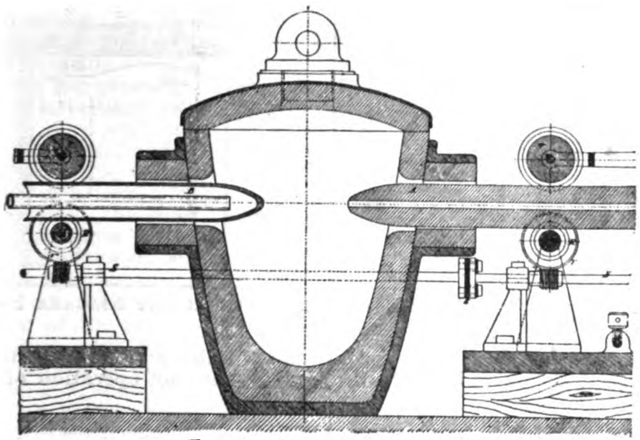

FIG. 1.—SIEMENS FURNACE.

opens a new field to the inventor not only in the perfection of the furnace itself, now an extremely crude affair, but the field is also alluring in holding out as it does the promise of giving to the world of science new combinations of matter, as well as that of producing rare and difficult chemical combinations upon a cheap and commercial scale. It is probably because this possibility has but recently become known that the electric furnace has received so little attention, and has therefore remained comparatively unimproved for twenty years.

The possibility of making calcium carbide on a commercial scale by electrically heating the ingredients, lime and coke, to the required temperature of combination, was its first great achievement and gave an immediate and lasting stimulus to electric furnace working, and we may soon expect to see a new born engine of science capable of applying the highest possible temperatures to chemical reaction.

As chemical affinity or attraction, determining which elements unite, is purely a question of temperature, so it may be well said that there are to all intents and purposes different chemistries at different temperatures.

Thus, through a wide range of temperature above and below normal, carbon's strongest affinity is for oxygen; but at the temperature of the electric arc the greater part of the carbon present in a mixture of lime and coke, unites with the calcium of the lime to form carbide of calcium (CaC_2), only a small portion uniting with the oxygen present to form carbonic acid gas (CO_2), as indicated by the formula for making calcium carbide, as follows:

$$2CaO + 5C = 2CaC_2 + CO_2.$$

The electric furnace may indeed prove a storehouse of surprises for both the scientific and the commercial world. Moissan has made diamonds by its aid, and, although they are not as yet a commercial article, there is little reason to doubt that in time they will be.

Historically the electric furnace dates from the seventies, and, though it is difficult to say when it was first mentioned or used, the first patent of record describing such an apparatus that I have been able to find bears the name of Charles William Siemens and is dated 1879. The principal drawing of the patent is here reproduced in Fig. 1, and shows simply an ordinary crucible with internally projecting electrodes for

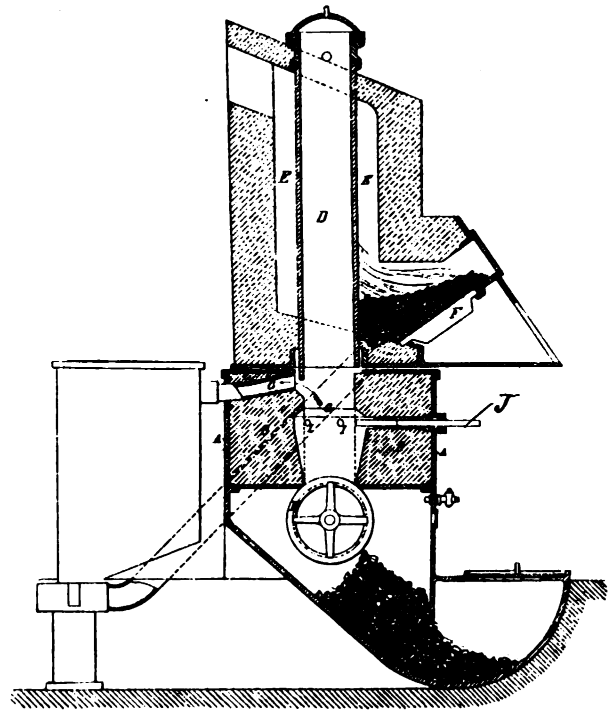

FIG. 2.—FAURE FURNACE.

establishing an arc within. The following excerpt from the specification describes all the essential elements of the modern electric furnace, although this one is, strictly speaking, only an electric crucible.

"In applying the electric current to the production of intense heat for the fusion of refractory substances I employ two carbon rods, fitted to slide toward each other horizontally, within water cased tubes, which are attached to the

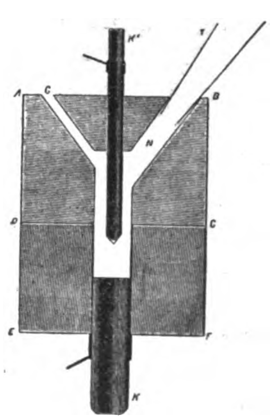

FIG. 3.

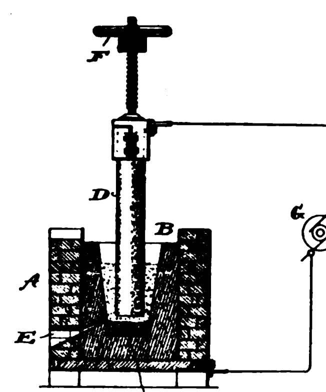

FIG. 4.

opposite sides of a crucible made of highly refractory material, such as lime or alumina, also water cased if necessary.

"The substance to be fused is introduced into the crucible, and the carbon rods are advanced sufficiently near to each other to form the voltaic arc within the crucible. They are thereafter made to advance by clockwork, each at a speed proportioned to its rate of consumption, so as to maintain the arc always within the crucible. As the heat in the crucible increases, the resistance to the voltaic arc within it diminishes, and consequently the arc can be elongated, an ef-

fect which results from the automatic retardation or stoppage of the feeding clockwork. In some cases, instead of employing carbon for the terminals, they may be made of the material that is to be fused, when it has sufficient conductivity."

The second in chronological order is, in fact, an electric furnace, and bears the equally illustrious name of Camille Alphonse Faure. His furnace is shown in Fig. 2, and is described as being adapted to the smelting of iron and other ores. In the figure a number of electrodes, J, project radially into the center of the furnace through holes, I, I, etc., and through the arcs maintained between them the material to be treated is caused to fall. There is no evidence that this system of furnace ever found general use. The patent is dated in 1882. So much for history.

The ordinary electric furnace of to-day finds its expression in some modification of that shown in Fig. 3, which represents a good form of furnace for laboratory work. There are two electrodes or circular carbon pencils, K and K', the one in the base of the furnace being fixed, the other being movable vertically. The furnace proper is made of two blocks of lime placed one above the other and separable along the line, C D, so that the contents can be readily removed when the operation of fusion is completed. A tube, S, permits feeding the material to the arc and the vent, G, allows the gases to escape.

It is but a step from this form to that shown in Fig. 4, the early form of the Willson and other American furnaces. In this type a fixed block of carbon, C, placed in the base of the furnace chamber, forms the lower electrode and a movable carbon pencil, which may be eight or ten inches in diameter, is the upper electrode. The tuyere pipe, E, allows the product of fusion to be drawn off when it is of a sufficiently fluid character to flow freely.

It is an easy step to pass from this form to the historic Willson furnace of Spray, North Carolina, shown in Fig. 5, and in which, it is believed, carbide of calcium was first made on a commercial scale from a mixture of lime and coke, as per formula given above. This furnace had electrodes of rectangular cross-section, about ten by twelve inches, and the output of a single run was a nugget of carbide some two or three feet high and a little over two hundred pounds weight. The first lot of electric furnaces at Niagara Falls turning out nuggets of about eight hundred pounds each differ in no material particular from the one at Spray shown in Fig. 5, except in matter of size and output. More recent developments, however, have introduced numerous innovations, and the tendency is to constantly increase the size and output of the furnace. While no new principles of operation have as yet been introduced into commercially working furnaces to

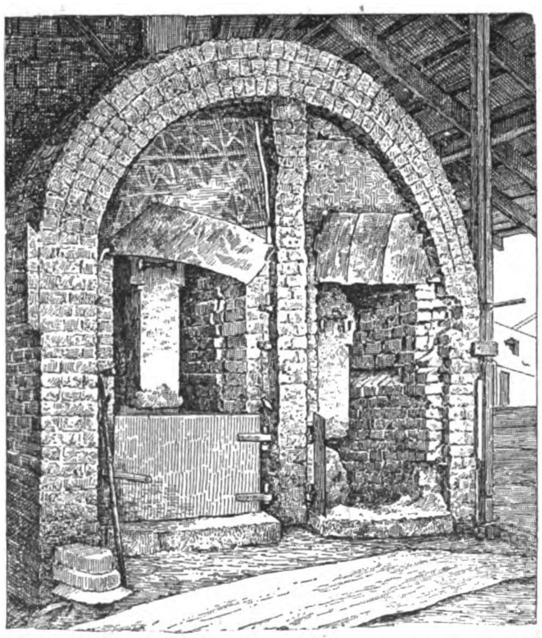

FIG. 5.—WILLSON CARBIDE FURNACE AT SPRAY, N. C.

my knowledge, they will doubtless make their appearance at an early day.

The recently constructed furnaces at the Niagara Falls plant for making carbide are designed as 1,000 h. p. units, and turn out a nugget of from 800 to 1,000 pounds at a single operation. These stacks are about thirty feet high, and are built on the general lines shown in Fig. 6. In this form a hinged base, D, forms a lower electrode, and its removal to the downward hanging position allows the product of an operation to be dumped into a cart that is run in under the furnace. The upper electrodes are counterweighted and movable

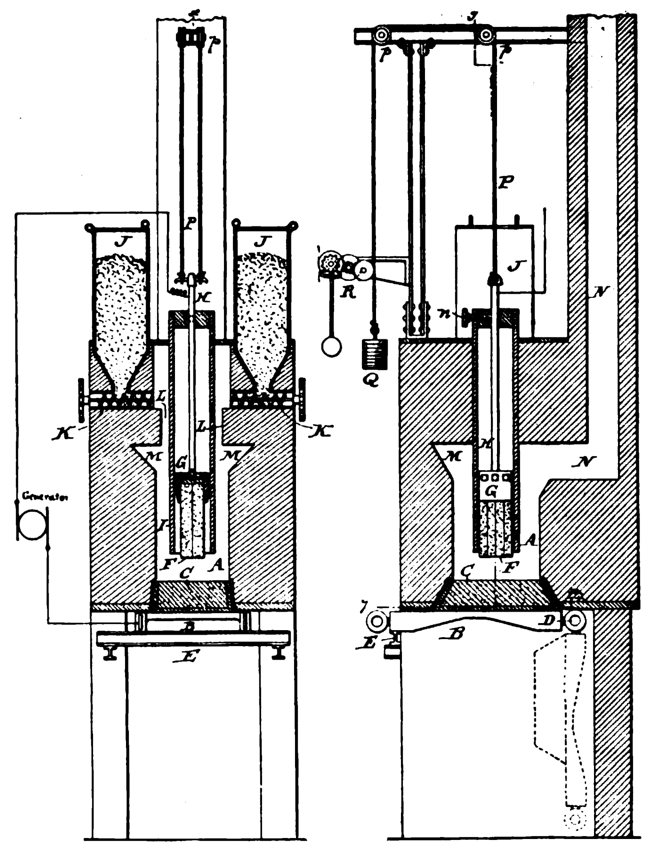

FIG. 6.—IMPROVED WILLSON CARBIDE FURNACE AT NIAGARA FALLS.

as indicated. Hoppers, J, J, contain the material for treatment, which is fed into the arcing space by operation of the driving screws, K, K.

ELECTRICAL MACHINE SHOP PRACTICE.—IV.

BY JAMES F. HOBART, M. E.

EVEN as simple a thing as driving a small lathe by means of an electric motor, is not always done as it should be, even in the machine shop. What conditions of arrangement are then to be expected in manufacturing shops?

Fig. 14 shows something of this kind. A small lathe, of about 10-inch swing, 3 feet between centers, was put in for the purpose of making repairs to arc lamps, and a motor was put in to drive the lathe, the arrangement being as shown in the engraving. This is a very common arrangement when small motors are put in to drive machinery; and it is a very bad arrangement. The pull comes all on one end of the shaft, and the action is to tip up one end, throwing it out of line and causing the belt to run off, to say nothing of the possibility of pulling the armature against the field of the motor as the wearing continues.

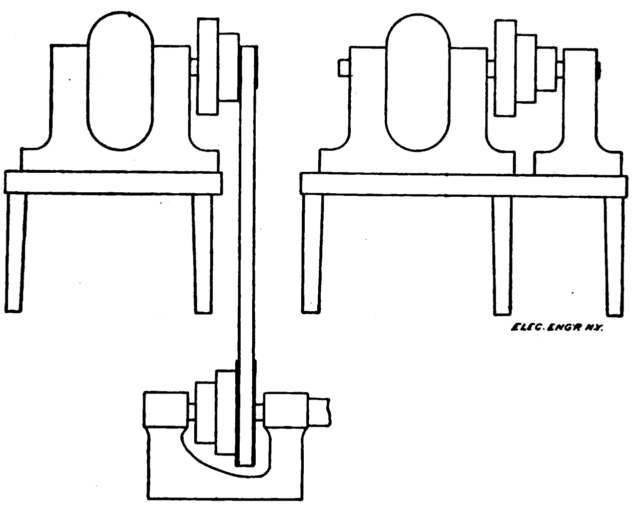
The arrangement is a very bad one, and should never be used. Another bearing should be made outside of the pulley, and it would be an excellent point for the makers of small motors to consider the matter of making long base frames for their machines, to be had at will, and carrying an outside standard, or pillow block. The wearing down tendency was only corrected in this machine by extending the wooden shelf as seen in Fig. 15, and putting another bearing outside the step pulley. The shaft had to be lengthened for this, but that was only a little blacksmith and machine shop work.

The making of electromagnets, particularly the kind with hard rubber heads as used for telegraph instruments, is a matter that requires a good bit of special machinery to make them profitably in large quantities, but for a few, or even a few hundreds, some jigs can be rigged up to do the work at pretty low cost.

Fig. 16 shows one of these magnets. It consists of the soft iron core, into the end of which some non-magnetic metal has

been placed as indicated by the small circle in the end of the magnet core. This is to keep the armature from sticking, "freezing," the telegraphers call it, when current is broken in the magnet winding.

The hard rubber heads are pressed on, the friction between



FIGS. 14 AND 15.

the rubber and the iron core being all that holds, or that is necessary to hold them in place.

The heads are shown by Fig. 17, the finished head, a, being ready for pressing on the core. The shape, b, shows a head as it is pressed out of a sheet of hard rubber. It is simply a plain disc without a hole in it. Or, the discs may be sawn off of a hard rubber rod of the required size.

The chuck, shown in Fig. 18, is screwed to the spindle of a Fox, or a turret, lathe. The spindle of such a lathe is shown at a, with the split chuck, b, put into it. This chuck is also made hollow, and a hollow plunger, c, fits inside of it. The spiral spring, d, serves to keep the plunger in place; also to force out anything that might be in the chuck when it is opened. There is a little shoulder in the hollow chuck just back of the plunger which prevents the plunger from being pressed back more than a certain distance. The thread on the chuck is taper, and the circular nut, e, is turned by the handle, f, which is left in place when the lathe is running.

To use this chuck, one of the hard rubber blanks, b, Fig. 17, is pressed on at a time, a pair of special chucks being used, against the shoulder. The blank is held in place while the nut is screwed home. Then the lathe is started up, and the turret tools soon make a finished magnet head out of the hard rubber blank. The operator soon becomes so expert that he can hold the blank in with one hand, and hold the nut lever, too, while he starts the lathe with his other hand, letting the first few turns of the spindle do the screwing up of the chuck. This tool is self-clearing, the finished head being expelled by the plunger as soon as the chuck is opened.

Another little kink is in putting the heads on the cores; the heads are forced on by screw pressure, an ordinary lathe spindle being used for the purpose. In one method, one head is pressed on at a time, a pair of special chucks being used, the one put into the live spindle being fitted to receive one of the rubber heads, and the little chuck that is placed in the tail spindle looks just like a small drill pad, and is cupped about a 1-16th of an inch to receive the end of the magnet core. In fact, the tail chuck is cupped to exactly the distance that it is desired the cores to project beyond the hard rubber heads. When the cores bring up in the bottom of each chuck, there is no more pressing to be done on that magnet; hence, they are all pressed on exactly alike.

Another jig that is used where there are many magnets of the same size to put up, consists of a brass casting built on the same principle as the babbitting jig, Fig. 11 (see The Electrical Engineer of July 15), and the iron core is laid on some bearings which hold it just high enough to come central with a couple of heads which are slipped into recesses, one at either end of the core. The three pieces being in place, the tail spindle is forced up, and a plunger attached to it, forces the heads into place, both at the same time. This rig is a time saver, but it cannot be used for several sizes and lengths of bobbins, as the first described rig can.

Working hard rubber is one of the things that the electrical machinist has to do, and the tools that can be profitably used in such work are varied. Some of the sheets of hard rubber can be cut with any circular saw as freely as wood, but other sheets will take the teeth off a saw as fast as it can be filed. In such sheets there seems to be a kind of grit which works about like emery. Sheets of this kind should be rejected. It does not pay to work them.

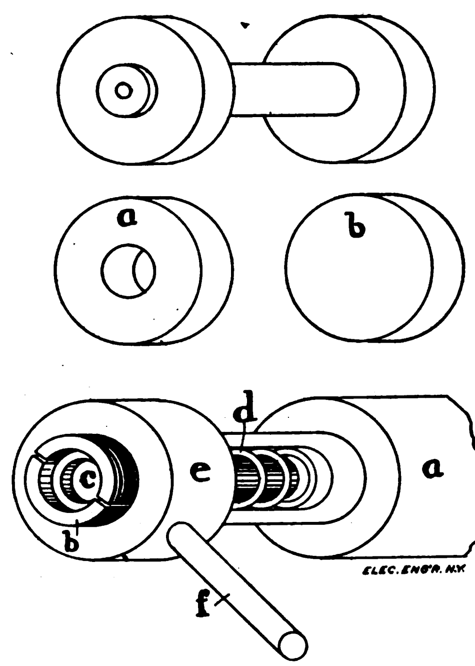
For working the better class of hard rubber sheets, a saw with teeth not over ¼ of an inch pitch should be used, and the saw need not be over 1-16th of an inch thick, and 4 or 5 inches in diameter. The teeth should all be filed square across, then the points will be like little chisels, and cut all along their length, instead of only at the very point, as is the case where the saw teeth are filed "fleaming"; that is, with the outside of the tooth the longest. This is the form of filing used for cutting crosswise of the grain in wood. Some saws are filed a little that way for splitting wood, but for the hard rubber business, file exactly straight across and the saw will cut better and stay sharp longer. Too much attention cannot be given to this point.

The set of the saw should be very slight. Only barely enough to permit the body of the saw to pass without sticking should be allowed, and what set there is should be given by bending out almost the whole tooth, instead of merely the point, as is often done by some saw filers. In addition to these points, the saw must be very true sidewise, without lumps or bunches, and it must, furthermore, be as round as it is possible to make it by holding a bit of emery stone squarely against the saw every time it is to be filed.

In connection with this matter, the saw must be a good fit on the mandrel. If too large, a bushing should be dovetailed in, and kept there by riveting. There is a way of using a saw too large for the mandrel, but it is not a sure one unless a great deal of care is taken by the workman to handle the saw in exactly the same manner every time he puts it on the mandrel, as follows:

Make a mark on the saw, using a center punch for the purpose, or, as some men do, take the maker's name as a mark, but the center punch mark is the best, for it allows a similar mark to be made on the mandrel collar, whereas if the maker's name be used, there is a chance of making a mistake. But whatever marks are used, bring them both uppermost, on saw and collar, then place the saw carefully in place with the marks in the position described, put the loose collar in place, and screw up the nut, keeping the marks directly on top all the time.

The principle of the matter is: If both marks are kept on top, the slack in the mandrel hole will be directly downward, and if the saw is rounded up while in this position, it can be replaced exactly again, by keeping the marks uppermost at the time of putting on the saw. If the mandrel were known to be perfectly true, there would be no necessity for marking



FIGS. 16, 17 AND 18.

that, but as there are often some dents to be found in the mandrel, the precaution must be taken of keeping it in one position also, when arranging the saw.

A large part of the work devolving upon the regular machinist in electrical work is the making of dies and jigs for the duplication method of manufacture. To this end a great deal

of grinding of hardened steel has to be done, and for plane surfaces there is nothing better than to rig one small or medium-sized planer permanently for this work.

Get a revolving vise that can be bolted to the top of traveling platen, and is graduated so as to be set to any required degree. Remove the tool box from the saddle and put in its place an emery wheel so hung that it can be turned to cut in almost any plane, from vertical to horizontal. Special machines of this class are in the market, but it is often desirable to make use of one on hand. But before deciding to make any planer into a grinding machine, test the planer thoroughly to make sure that the platen travels true.

If there have been bunches worn in the ways, or hollows ground down in them, all these imperfections must be removed by planing up the bed and ways, before a good job of grinding can be done on the machine after it is altered to suit the new purpose. A planer, or a plane surface grinder, will reproduce in the work it does each and every one of the imperfections that exist in the platen or in its slides.

Any machine that has been set apart for this kind of work, in order to keep it so as to do good work, must be so arranged that the dust from the emery wheel will not, and cannot get on to the sliding surfaces. To secure this end, it may be necessary to arrange a hood over the wheel, or over a certain part of it, so as to catch the emery and metal dust as it leaves the wheel. If this funnel or hood be also connected with a small exhaust fan, the work done will be much better, and the life of the workman in charge of the grinding machine will be considerably prolonged. Emery dust is very bad when drawn into the lungs.

ROTARIES FOR TRANSFORMING ALTERNATING INTO DIRECT CURRENT.[1]—I.

BY C. F. SCOTT.

THE characteristic of alternating current which gives it a high commercial value is the facility with which it may be transformed from one pressure to another. An electric system may combine both the advantages of the alternating current for transmission and of the direct current for utilization, if there is a means of transforming alternating into direct current.

Methods of Transformation.—The simplest arrangement of ordinary apparatus for transforming from alternating to direct current is found in an alternate current motor driving a direct current dynamo. The two machines may be mechanically connected by belt or otherwise, or the two armatures may be mounted upon one shaft and the two fields placed upon the same bed plate. The arrangement may be further simplified by using a single field and a single armature with two windings, one for receiving the alternating current and the other for generating the direct current. A further simplification is made by uniting the two windings into a common winding suitably connected both to collector rings for receiving the alternating current and also to a commutator for delivering the direct current. This arrangement constitutes the ordinary rotary transformer, rotary converter, or rotary such as has been finding a widening and important practical application during the last few years.

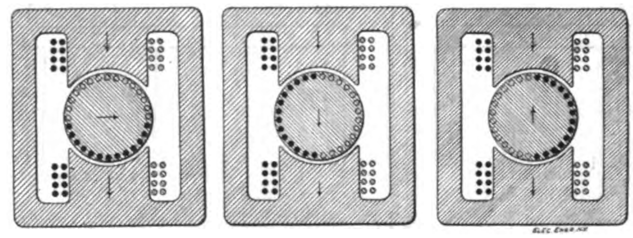
An armature for a rotary may readily be made from the armature of a direct current machine by connecting collector rings to certain commutator segments, or to the points in the winding to which they are connected. The part of the armature winding between two collector rings is continuously changing position with reference to the field poles and is, therefore, generating a continuously changing e. m. f. which appears as an alternating e. m. f.

The ordinary rotary is a combined alternating current motor and direct current generator. It possesses certain characteristics of a motor, others of a generator and still others which result from the combined action of the two. The characteristics of the synchronous motor will be considered in detail, then those of the direct current generator and finally those of their combination or a rotary.

A Synchronous Motor.—If two similar alternating current machines be driven from the same counter-shaft at the same speed and have the same field charge, they may be connected together in multiple in the same way that two similar direct current machines running at the same speed and with equal field charges may be connected in multiple. If the belt be thrown off one of the machines it will run as a motor, receiving its current from the other machine.

A motor which receives current from a supply circuit must conform to the characteristics of that circuit. A direct current shunt motor for example must run under such conditions that the e. m. f. of its armature is equal to the e. m. f. of the supply circuit. This means that the speed, the field current and the work done must be mutually adjusted in such a way as to meet these conditions. If the field current is reduced the speed will increase; if the load be increased the speed will, in general, decrease.

In like manner a synchronous alternating current motor must adapt itself to the conditions of the circuit, not only in e. m. f., but in speed. It must run at a definite constant speed which is in a ratio to the speed of the generator determined by the relative number of field poles in the two



FIGS. 1, 2 AND 3.

machines. A change in the field charge of a synchronous motor cannot be compensated for by a change in speed as is the case in a direct current motor.

Effect of Variations in Field Strength.—If the field current of the alternating current motor be reduced there can be no increase in speed and there must necessarily be some other means for making the e. m. f. of the motor correspond to that delivered by the generator. If the field charge of the motor be decreased, say 20 per cent., it will be found that a very considerable current flows between the generator and the motor, possibly equal to the full load current of the motor. This current is evidently a so-called "wattless" current for, although it is delivering apparently the energy required by the motor at full load, it is actually delivering only sufficient energy to run it without load. The current flowing is, however, different from the current which flows when the motor is loaded under normal conditions, as the two currents do not have the same time relation to the e. m. f. In a loaded motor under normal conditions the maximum current occurs at the time of maximum pressure and zero current at the time of zero pressure.

The position of the armature at the time of maximum current is shown in Fig. 1. The armature conductors which are shown in black circles are those carrying current in one direction, while those shown as open circles are those carrying current in the opposite direction. The armature is in a two-

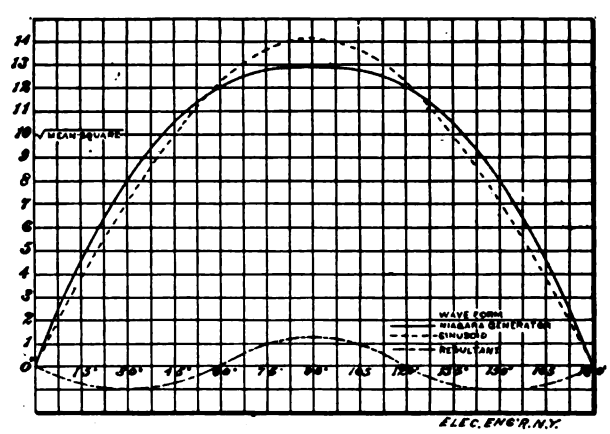


FIG. 4.—TWO-WAVE FORMS AND THEIR RESULTANT.

pole field and the direction of the current in the field coils is represented in the same way, by dark and light circles.

When a motor with a low field current is connected with a circuit and receives a heavy armature current, this current does not flow simultaneously, or in phase, with the e. m. f. The maximum current occurs when the armature has revolved through 90 degrees (in which position the e. m. f. generated is zero). The position of the armature at the time of maximum current is shown in Fig. 2. It will be readily seen that in this position all the wires which carry current in one direction are on the same side of a line running through the middle of the field poles, and that the armature current is in a posi-

[1]Abstract of a paper read before the National Electric Light Association at Niagara Falls.

tion to directly aid the current in the field winding in its magnetizing effect as is indicated by the arrows. This is equivalent to strengthening the field current. If the field current of the motor be reduced 20 per cent., and the e. m. f. of the circuit remain the same, then there will be sufficient current through the armature to make up for the 20 per cent. reduction in the ampere turns in the field.

In the generator, however, the position of the armature coils when this current flows is such that it acts against the current in the field, thus reducing the effective magnetization. The position of the conductors at the time of maximum current is shown in Fig. 3, in which the magnetizing effect of the current in the armature is seen to be directly opposed to that in the field. If the generator is large in comparison with the size of the motor, the effect may be small, but if the motor be large it may be considerable. If the two machines be of the same size and the e. m. f. of the generator is 1,000 volts and that of the motor 800 volts before they are joined, then the resulting e. m. f., when the motor is connected to the generator, will be about 900 volts. The current flowing through the two armatures will reduce the magnetization of the generator by opposing the ampere turns of the field, while in the motor the magnetization will be increased as the armature ampere turns assist those of the field.

If the field current of the motor be increased so that its e. m. f. before connection to the generator is, say, 1,200 volts, then a current will flow which demagnetizes the motor and magnetizes the generator. If the two machines be of equal size so that a current produces about equal effects in the two machines, then the resulting pressure will be about 1,100 volts. It is in fact possible to run a motor without any field charge at all, but with an armature current sufficiently large to produce all the magnetization required. On the other hand, it is also possible to run a motor having a charged field from a generator which has no field charge. The current in the armature magnetizes the generator while reducing the e. m. f. of the motor. In this case the e. m. f. at the terminals is about half the e. m. f. which there would be if the generator had its normal field charge.

When a motor is running with load, the current which delivers energy to it is in phase with the e. m. f. and produces only a slight effect upon the magnetizations and e. m. f.'s of the machines. When a motor is carrying load the current to it increases if the field be too high or too low, as the e. m. f. of the motor must be made equal to that of the circuit by an additional magnetizing current in the armature if the field current is not properly adjusted. These conditions are illustrated by the relative directions of the arrows in the first three figures.

In the illustration, which has just been cited, it has been assumed that there is little or no resistance in the circuit joining the generator and motor. If, however, there is a considerable resistance in the circuit between the two machines, then the e. m. f.'s on their terminals will in general not be the same, that of the motor will usually be lower than that of the generator, as it is in direct current circuits. It is possible, however, if there be inductive resistance in the circuit between the two machines, and if the field charge of the motor be increased, to make the e. m. f. at the motor terminals equal to or greater than that at the generator. If the field current of the motor be increased as it is loaded, the e. m. f. at the motor may be maintained constant at all loads or may be increased as the motor is loaded. On the other hand, if the field current of the motor be too low there may be a greatly increased drop in generator and in transmission circuits. There is always a certain definite motor field charge with which the motor will carry its load with a minimum current.

Any variation in field charge increases the current required by the motor and this current, although it may be useful for regulating the e. m. f., causes increased heating and losses in the armature usually and the transmission circuits also.

Effect of Variations in Wave Form.—The e. m. f. of a synchronous motor must be adapted to that of the circuit not only in its average intensity, but also in its wave form. Two alternating current machines may give equal e. m. f.'s of, say, 1,000 volts effective, although one has a maximum e. m. f. of 1,410 volts and the other of only 1,290 volts. At some other part of the wave, say when the e. m. f. of the first machine is 700 volts, that of the second machine may be greater, or 800 volts. The result is that at some instants the first machine would have an e. m. f. over 100 volts higher than the second machine, and at other times the second machine would have an e. m. f. higher than the first. If two such machines be run in synchronism, either both as generators or one as a generator and the other as a motor, the difference between their e. m. f.'s at different times during each alternation gives an e. m. f. for sending a current back and forth between the armatures. This e. m. f. is one of a higher frequency than the normal frequency of the circuits usually of three or five times the frequency, and it evidently cannot be avoided by changes in the field charges of the machines. This high frequency current causes extra heating in the armatures and transmission circuits, it reduces output, it causes increased drop and it contributes to "pumping."

The figures used in the foregoing example are taken from the published curve of the Niagara generators and the sinusoid. The result indicates what may be expected if a machine whose e. m. f. wave is a sinusoid be connected to the Niagara circuits. This is illustrated in Fig. 4, which shows the Niagara wave, the sinusoid and their difference, or the e. m. f. which would send an idle current through the circuits. This is equal to about 10 per cent. of the normal e. m. f. of the circuit.

Effect of Variation in Speed.—The effect which a given difference of speed makes upon the electric system depends largely upon the number of poles of the alternators. The variation in speed may be such that one armature is at times 1-100 of a revolution in advance and sometimes 1-100 of a revolution behind a second armature. If the machines have 100 poles then the one armature which at one instant agreed in phase with the other, so that its e. m. f.'s will be of exactly the wrong phase and a heavy current will flow through the armatures. If, however, the alternators be two pole machines, then an advance of only 1-100 of a revolution of one armature ahead of the other will cause so trifling a difference in e. m. f.'s as to produce little or no appreciable effect.

"Pumping" of Motors.—This irregularity may be caused by variation either in speed or in e. m. f. Variation in the speed of a generator tends to cause a corresponding variation in the speed of a synchronous motor. The motor cannot assume instantly the speed required by the new speed of the generator. When this increases then the motor armature begins to increase in speed but lags slightly. At this time the motor receives an increased current because its armature is not in the normal position for the new frequency and because additional current is required for supplying the energy necessary for increasing the speed. The additional current produces a difference in the magnetization of the field, which must again be altered when the generator speed decreases below the average. The motor is, therefore, undergoing a slight variation in speed which does not exactly correspond to that of the generator, and it is undergoing changes in its magnetic field strength which cause it to receive from the circuit a fluctuating current, and this may in turn affect the e. m. f. upon the circuit. The motor armature at certain times receives more than its average amount of energy from the circuit and at other times may even return energy to the circuit. The e. m. f. of the circuit is dependent, not upon the generator only, but upon the combined action of the generator and the motor, and the fluctuating current to the motor may produce a fluctuation in the e. m. f. of the circuit. A fluctuating e. m. f. upon a circuit, such as would cause a flickering or varying light in an incandescent lamp, will cause a motor to take an additional current either lagging or leading at each variation.

Torque at Low Speeds.—A synchronous motor possesses but little torque at any speed except the synchronous speed. In general it cannot be started except by the use of some auxiliary apparatus or at the expenditure of a heavy current in proportion to the torque developed. It must be connected to the circuit or "synchronized" when it has attained exactly the proper speed, when the e. m. f. is equal to that of the circuit and has the right phase relation. When it is slightly below synchronism its torque is greatly reduced. A momentary overload upon the motor may cause it to drop from synchronism.

Resumé of Characteristics of a Synchronous Motor.—Among the characteristics of a synchronous motor which have a direct bearing upon its practical operation are the following:

An ordinary synchronous machine has small starting torque and requires either a heavy starting current or is started by auxiliary apparatus. A considerable amount of switchboard apparatus is required and care must be used in connecting the machine to the circuit.

If there be a sudden increase in the generator speed, a synchronous motor may not be able to increase its speed quickly enough to prevent dropping from synchronism.

The generator speed must be fairly uniform throughout each revolution in order to prevent fluctuation in current and "pumping" of synchronous motors.

If the e. m. f. of the circuit be momentarily lowered (e. g., by connecting a motor to the circuit when it is not in phase, or by overloading a motor and causing it to drop from synchronism, thus producing a heavy current), or if the e. m. f. be cut off the circuit momentarily (e. g., by switching the

circuit from one dynamo to another), the synchronous motor may lose synchronism and stop.

The field strength of the synchronous motor must be adapted to produce an e. m. f. fairly approximating that of the circuit or there may be an excessive current either leading or lagging.

A lagging current produces a greatly increased drop in e. m. f. in generator and transmission circuits. A leading current reduces drop in e. m. f. and neutralizes lagging current. If a synchronous motor and an induction motor be supplied by the same line, the leading current to one may neutralize the lagging current to the other so that the line carries only the current necessary for transmitting energy to the motors.

The synchronous motor must have a wave form fairly approximating that of the circuit to which it is connected or there will be a large idle current flowing.

The e. m. f. of the circuit which operates a number of machines in synchronism is dependent upon the field charges of all the machines; ill adjustment of any of the machines affects the circuit; an accident or carelessness in the attention to any of the machines may disable the whole system.

Each synchronous machine in a system endeavors to impress upon the system its own characteristic e. m. f. and wave form. If the wave form of a large synchronous motor be different from that of the generator, it may alter the resulting wave form on the circuits, which may make it unsuited for other machines which are connected to the circuit.

A synchronous motor which has a bad wave form, an improper field charge, or which is connected to the circuit when out of phase, or which pumps, may affect other motors on the system which are honestly striving to conform to the normal conditions of the circuit, but which become innocent victims of the irregularities of some distant co-worker.

THE EFFECT OF ARMATURE INDUCTANCE UPON THE ELECTROMOTIVE FORCE CURVES OF AN ALTERNATOR.[1]

By W. E. GOLDSBOROUGH.

THE subject of the regulation of alternating dynamo electric machines, considered as a function of the inductance of their armature coils, has been treated by a number of writers, and during the last few years has attracted much attention.

In looking up the bibliography of the subject, the author found that but few records have been published of the actual value of the inductance of the generating coils of these machines, and that even less data are available regarding the real nature of the periodic fluctuations that take place in this quantity.

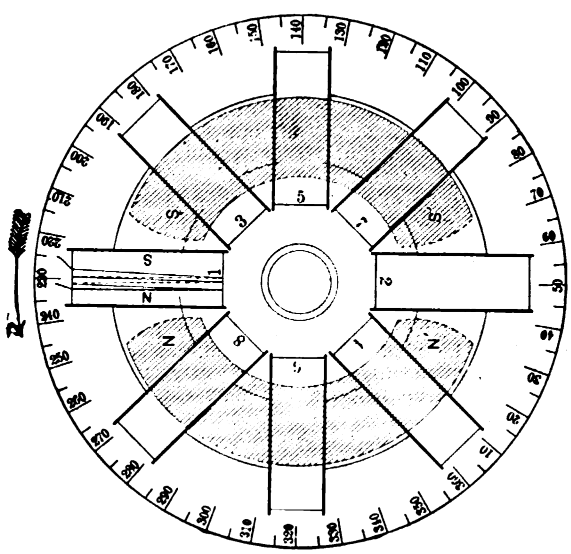

FIG. 1.

Apparatus and Method Employed.—The experiments were made upon a three-light Brush arc machine, fitted with the necessary exploring coils, collector rings and revolving contact-making device. The core of the armature is of the ring type and is built up of laminated iron stampings, held together by laminated iron bands passing around the core between the successive layers of stampings.

The method employed in making determinations of the self-induction of the armature was as follows: An exploring coil of 42 turns of No. 36 B & S copper wire was wound over armature coil 1, and connected in series with the field coils of a high resistance Nalder ballistic galvanometer and an adjustable non-inductive resistance. A constant exciting current of 10 amperes was kept flowing through the field circuit at all times. During the time of taking any one set of readings, a direct current of definite value was maintained in coils 1 and 2, except when the deflections were made.

Armature Inductance.—In determining the coefficient of self-induction coils 1 and 2, coil 1 of the armature was placed at the 230 degs. position, as indicated in Fig. 1, since at this point the magnetizing power of the coils was least, owing to the large magnetic reluctance of the circuit traversed by the lines of force emanating from the coils.

The curves obtained bring to light some very interesting facts. They show that the maximum coefficient of self-induction occurs when the coils are in the 145 degs. position and the current flowing in them has a value of 2.5 amperes; under these conditions their inductance is over .172 henry. They indicate that as the armature current is varied from zero up to its maximum safe value, the inductance of the coils undergoes very marked and relatively rapid changes.

It is also interesting to note that between no load and full load, the crest of the induction curve moves through an angle of 30 degs., or over one-fourth of the width of the pole faces. The large teeth of the armature core do not seem to have the effect of causing any marked irregularities in the inductance curves. It is noticeable, however, that there is a slight hump in all of them at the 90 degs. position. This is caused when the teeth immediately behind the coils pass the pole tips. The same effect is produced by the other teeth, but it is too slight to appreciably affect the readings.

Electromotive Force Curves.—A series of electromotive force curves taken from the machine illustrate the gradual change in the wave form of the effective electromotive force as the load increases. By the effective electromotive force is meant the electromotive force that is in phase with the current and overcomes the ohmic resistance. A curve obtained with zero current in the armature shows that the "fundamental" or internal electromotive force wave of the machine is not symmetrical about the 140 degs. ordinate.

The activity displayed by the eddy currents in heating up the pole tips is quite remarkable. The curves obtained plainly indicate that much greater magnetic disturbances occur in the leading pole tips than at other points in the pole faces.

In the development of the experimental results contained in this paper the dynamo was loaded by inserting sets of incandescent lamps in the external circuit. A special point was made of keeping the external circuit entirely free of any inductance. It is a curious coincidence that the alternating current inductance curves all cross at a common point, namely, at the 164 degs. position.

Counter Electromotive Force Curves.—A set of curves are given showing the cyclic variation of the induction set up in the coils by the armature current obtained by plotting the products of the ordinates of corresponding points on corresponding current and inductance curves. The counter electromotive force curves are highly irregular in form. They oscillate from the positive to the negative value twice in a period instead of once, and are generally useful in filling up gaps. The whole series of inductance curves shows that the curves follow one another in regular order in spite of their lack of symmetry, and it is interesting to note the receding of one and the building up of another "hump" in these curves.

Derivation of Current Curves.—The success attained in working out the counter electromotive force curves led to a series of calculations to determine to what extent the form of the current curves was influenced by the shifting of the phase of the inductance curves with the load. Curves are shown illustrating this effect.

It was noticed during the test that the armature reaction caused an increase in the total effective potential for certain ranges of load.

"LIFTED."

Mr. W. H. Reeves, Jr., of Redwood City, Cal., writes: "Your paper is certainly appreciated in this part of the country, for some one lifted my copy of June 30 before I had even a chance to look at it. Can you send me another, with Data Sheet?"

PROF. W. C. PECKHAM, of Brooklyn, N. Y., writing for back copies of The Electrical Engineer, says: "I find the numbers very valuable, more so than if loaded with equations and bristling with formulas."

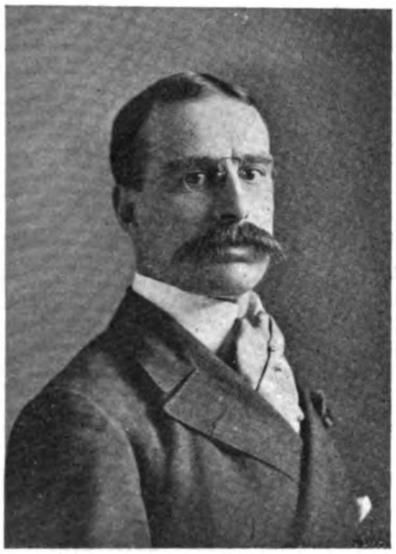
TELEPHONY AND TELEGRAPHY

THE STROWGER AUTOMATIC TELEPHONE EXCHANGE, AT AMSTERDAM, N. Y.



William B. Charles.

AMSTERDAM, N. Y., has one of the most modern and complete telephone systems in the country. The plant was built by the Amsterdam Automatic Telephone Company, incorporated in 1896, in which the leading business men of the city are interested, and, although all the wires are overhead, the construction is of the latest type. The officers of the company are Willis Wendell, president; George McClumpha, treasurer, and William B. Charles, secretary, and it was under the direct supervision of the last named gentleman that the system was installed.

Amsterdam is an important center for the manufacture of carpets and other textile fabrics; in proportion to its population, which is about 25,000, more carpet is made there than at any place in the country. It is a most enterprising city, and its citizens were desirous of having first class telephone service at moderate cost. The investors in the Automatic Company have endeavored in every way to meet the necessities of their fellow-citizens, and the following description of the plant will show that they have succeeded. The gentlemen who placed their money in the venture were the first to take up the automatic system on a large scale—before that time the automatic having been used only for interior purposes, or in very small communities. They have invested about $17,000 in the enterprise, and as that sum was spent wholly in the construction of a system for 200 subscribers, it necessarily follows that the plant is of an extremely hign order.

The system of making connections is that of the Strowger Automatic Telephone Exchange, of Chicago, whose system was described and illustrated in our last issue, as installed in Augusta, Ga. The subscriber's apparatus consists of a magneto bell, which also contains the transmitter, below that a box about the size of a Blake transmitter and a battery box underneath. On the face of the box below the generator and transmitter (which contains a switching device) is a plate on which all the numerals appear, commencing with No. 1 at the bottom and extending upward on the right-hand side to No. 0 or X. Corresponding with each number is a notch in which the finger of the subscriber is placed, when wishing to call, and the plate revolved until the stop at the bottom is reached. Upon being released the plate returns to its normal position, and in doing so transmits the signal. This operation is repeated for each figure of the number desired, the calls being made in the order of hundreds, tens and units. After the operation above described is made the subscriber rings the bell, thus securing the attention of his correspondent. By hanging the receiver on the hook, when through talking, the switch is returned to normal. The whole operation is simple.

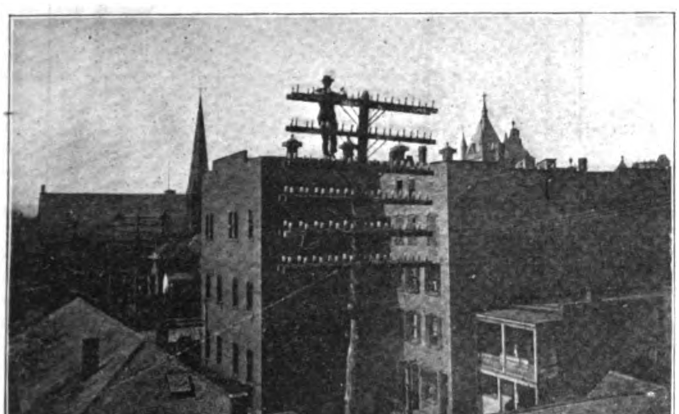
The office of the Automatic Company is at 52 Market street, Amsterdam, N. Y., the front room of the apartment which it occupies being devoted to the general switching apparatus and auxiliary devices. Although the advocates of the automatic system claim that no "central office" is required, there is, nevertheless, a "central," the only difference being that with the ordinary system an attendant is required to make the connections, while with the automatic that work is performed by the subscriber. The Strowger is practically a multiple switchboard; the switch of each subscriber being connected with that of every other subscriber. In the manual multiple board, every subscriber's line terminates in front of each operator in the exchange. In both systems the connections are made direct without the medium of trunk wires between different sections of the board. The Automatic Company's board requires but little space and, to protect it from dust and dampness, it is enclosed in glass. Unfortunately, the position of the board is such that it was quite impossible to secure a photograph of it for the benefit of the readers of this article. Unlike the manual system, the question of light and air is of but little importance in the operations of the automatic system, consequently the company placed its board and battery in a position suitable to its needs. It is most interesting to watch the connections being made, which are going on at all times, Amsterdam being a busy place. One side of the subscriber's circuit calls the hundreds and units, the other side, tens. The first call raises the switching arm (really the plug) up to the notch corresponding with the number of hundreds desired; the second operation turns the arm around to the number of tens, and the third raises it again to the number of units. Instead of seeing the "clearing out" drop fall, as in the manual system, the whole switch falls back to its normal position when released by the subscriber in returning his receiver to the hook.

The switch arm is of the knife blade pattern, which, of course, cleans the points of contact.

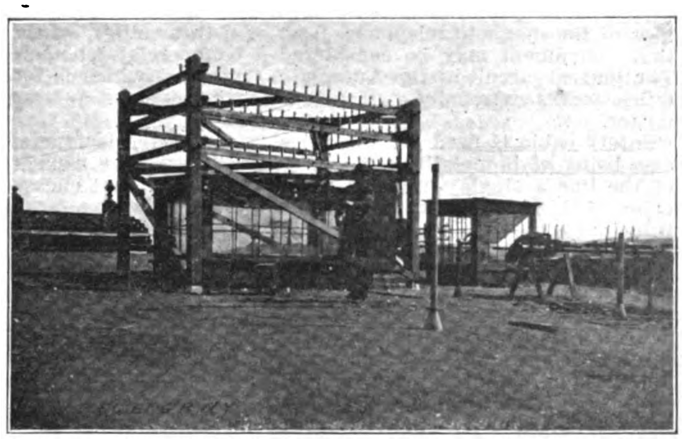
Power for the operation of the switches is supplied by storage battery, the total number of cells being fifty, divided into two sections each of twenty-five, connected in series, one section being charged from the electric light circuit, while the other is in service. An insulated bi-metallic wire, size No. 10 B & S, feeds the whole system.

The telephones used by the company were also manufactured by the Strowger Automatic Telephone Exchange, the transmitters being of the Hunnings type. Until quite recently the transmitter battery has been supplied by dry cells, but it has been deemed advisable to substitute therefor the Leclanché cell.

Amsterdam has no underground ordinance, consequently the Automatic Company built an overhead plant. No expense



LOOKING NORTH ON MARKET STREET FROM COMPANY'S OFFICE.



HOUSETOP FIXTURE ON OFFICE BUILDING.

has been spared, however, to have the outside construction as strong and as durable as possible. Main and Market streets are the busiest thoroughfares of the city and, when the company was formed, both sides of these streets were occupied by pole lines. To secure rights-of-way on these two streets, the Automatic Company entered into an arrangement with the Amsterdam Street Railroad Company and the Electric Light Company, whereby the former rebuilt the lines of the two last named companies on those streets, using 50-foot chestnut poles of standard specifications. The tops of the poles are reserved for fire alarm and police purposes and, in addition to this, the company gives six free telephones to the city. The telephone wires are immediately below the fire alarm wires on 14 pin cross-arms, and still further below, with a considerable gap, are the railway feeders and electric light wires. These poles also furnish the supports for the trolley wires on one side of the streets.

In the outlying districts, 40-foot chestnut poles are used, with 10 pin cross-arms, and in erecting many of these poles much difficulty was encountered owing to solid rock, necessitating blasting of holes. This, of course, added to the cost of construction. All poles are set just within the curb line. The company has 15 miles of pole line, almost all of its wires being carried on its own poles with very few house-top fixtures. It is appropriate to here mention an incident showing the advantage obtained by the Automatic Company through the use of bi-metallic wire. Last winter, the Young Block, on Main street, burned down, causing one of the largest fires ever seen in Amsterdam. The pole line of the company passed this block on the same side of the street. The water thrown on the flames passed through the telephone wires and, as the fire was checked or gained headway, the water on the wires alternately froze or melted. Notwithstanding this and the force with which the water was thrown on the line, not one wire broke and telephonic service was uninterrupted. Nor was it necessary, on the day following, to pull up slack, the bi-metallic remaining taut, although subjected to a severe strain. The longest circuit is four miles, being the connection to Hagamans.

Bi-metallic wire (steel center with copper surrounding it), manufactured by John A. Roeblings Sons' Company, and furnished by the Bi-Metallic Electric Transmission Company, size No. 14 B & S, has been used exclusively in the construction of this plant for subscribers' lines and tapping the general power feeder. The feeder wire is also of bi-metallic, size No. 10 B & S, insulated. This wire has given exceptionally good service from both electrical and mechanical points of view; its great strength has secured to the company uninterrupted service and its electrical qualities have given to the subscribers good talking wires, over which the articulation is clear and the volume of tone is all that is desired.

Not only does bi-metallic wire produce good results when used with battery transmitters, but it also improves the workings of the magneto telephone, used as a transmitter, so that that instrument may be considered a commercial telephone. The longest circuit of the Automatic Company, which is four miles, works extremely well, using the receiver as a transmitter.

Safety cable is used for the office "run in," the conductors also being of bi-metallic. To increase the carrying capacity of the line a single wrap, dry paper insulation, lead encased cable of Roebling make is suspended from the poles on the principal streets.

The company has 200 subscribers, all connected by metallic circuits and gives continuous service. The rates which it has established are extremely low, taking into consideration the quality of service; in fact, they may be called a liveable rate, liveable for both the company and the subscriber, and are $36 a year for business houses and $24 for residences. The cost of maintenance is very low, inasmuch as the company has but one employé, exclusive of officers, who are prominent business men of the city. This employé cares for all the workings of the company, including repairs to line, switching apparatus, telephones and collections, office work, etc. He also builds new lines, and is, in fact, manager, inspector, lineman, accountant, etc., combined. This position has been filled since the company started operations by Mr. C. O. Williamson, who, however, is about to leave in order to install other automatic plants built by the New York State Telephone Company. He will be succeeded by Mr. A. H. Foster.

SHOT FOR CUTTING TELEPHONE WIRE.

A few days ago a telephone wire was cut near Tacubaya, Mexico. The offender has been captured and will be shot, as the Mexican law prescribes that punishment for such offenses.

THE ADER PHOTOGRAPHIC CABLE RECORDER.

In a recent issue we noted the trial made on a new submarine cable-recording instrument, invented by M. Ader, the well known telephone inventor of Paris. Our contemporary, "La Nature," gives further details of this very sensitive instrument. It consists essentially of a very fine metallic wire stretched vertically in a long narrow magnetic field created

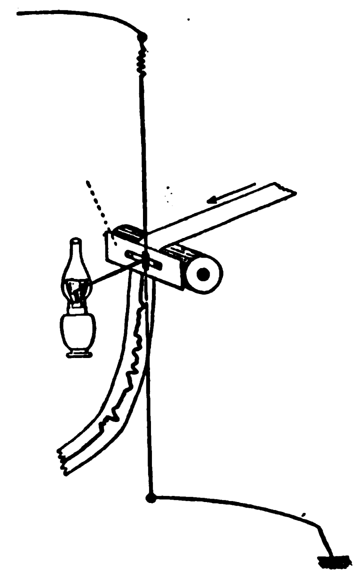


Fig. 1.—Ader Photographic Cable Recorder.

by a strong horizontal magnet, the poles of which surround the wire. The currents coming from the cable pass through this wire, which is driven perpendicularly to the line of the poles to the right or left, according to the direction of the currents.

In order to record the signals produced, M. Ader has devised an arrangement, shown diagrammatically in Fig. 1. Behind the wire and at its center is a plate provided with a horizontal slot. Behind this plate a strip of photographic

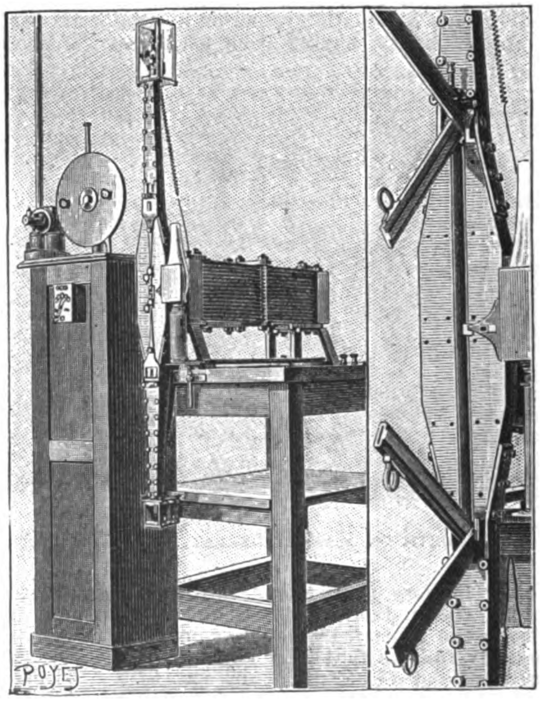

Fig. 2.—Ader Photographic Cable Recorder.

paper is rolled continuously, and in front of it is placed an ordinary oil lamp. The shadow of the wire is projected across the slot on to the paper and traces a line which reproduces exactly the same signals as those of the siphon re-

corder. After exposure to light, the paper strip is automatically developed in three tubes contained in a small, dark cabinet, and the signals formed are traced in white on a black background.

Fig. 2 shows the complete apparatus. The small cabinet to the left is the photographic laboratory. At the top there is an electric motor for driving the paper reel. The movable wire is in the vertical sheath, situated in front of the compound magnet. It can be inspected by opening the pole-pieces of the magnetic field, as shown at the right in Fig. 2. The wire is stretched at the top by means of a small dynamometer spring, with a force varying between two grams and five centigrams. The wire has a diameter of about fifteen-thousandths of a millimetre, and the magnet can carry 400 kilograms. The sensibility of the receiver is such that it gives very fine signals with one Callaud cell, through a resistance of three megohms.

The trials of the Ader apparatus were first made on the P. Q. cables, between St. Pierre, Miquelon, Newfoundland and Brest, France. One hundred and fifty letters a minute were obtained with the same clearness as ninety-five letters, by means of the siphon recorder on the same cable. This was in September, 1896. About two months ago trials were begun on the French government cables between Marseilles and Algiers. Here the siphon recorders work at 150 letters, or thirty words a minute. The Ader recorder worked with the same clearness 350 letters, or seventy words, per minute—that is, a gain of 60 per cent. in the first case and of 230 per cent. in the latter. The system can be worked duplex like any other system. We understand that M. Ader is now at work on a combination, which will permit of duplex working directly without repeating between Paris and New York.

THE EARLY COMMERCIAL DEVELOPMENT OF THE TELEPHOHNE.

WE give below the text of a circular issued just twenty years ago by Messrs. Gardiner G. Hubbard and Thos. A. Watson to push the commercial introduction of the telephone. The data is of a very interesting nature, particularly as it brings out the fact that only private line work was considered; there being not the slightest suggestion of a central exchange or the modern multiple board. It will also be observed that good results are not guaranteed for distances over twenty miles. The instrument "needs no battery." The circular is of four pages, the first being occupied with the announcement quoted below. Two other pages record experiments in Salem and New York, and quote the Award Report of Sir William Thomson, with a superfluous "p" in the middle of his name. The last page gives the opinion of R. C. and F. W. Downer, brokers in Boston, who under date of May 14, say they have had the telephones working between Boston and North Somerville for two weeks, and prefer them to the Morse system.

THE TELEPHONE.

The proprietors of the telephone, the invention of Alexander Graham Bell, for which patents have been issued by the United States and Great Britain, are now prepared to furnish telephones for the transmission of articulate speech through instruments not more than twenty miles apart. Conversation can be easily carried on after slight practice and with the occasional repetition of a word or sentence. On first listening to the telephone, though the sound is perfectly audible, the articulation seems to be indistinct; but after a few trials the ear becomes accustomed to the peculiar sound and finds little difficulty in understanding the words.

The telephone should be set in a quiet place, where there is no noise which would interrupt ordinary conversation.

The advantages of the telephone over the telegraph for local business are:

1. That no skilled operator is required, but direct communication may be had by speech without the intervention of a third person.

2. That the communication is much more rapid, the average number of words transmitted a minute by Morse Sounder being from fifteen to twenty, by telephone from one to two hundred.

3. That no expense is required either for its operation, maintenance or repair. It needs no battery and has no complicated machinery. It is unsurpassed for economy and simplicity.

The terms for leasing two telephones for social purposes connecting a dwelling house with any other building will be $20 a year, for business purposes $40 a year, payable semi-annually in advance, with the cost of expressage from Boston, New York, Cincinnati, Chicago, St. Louis or San Francisco. The instruments will be kept in good working order by the lessors, free of expense, except from injuries resulting from great carelessness.

Several telephones can be placed on the same line at an additional rental of $10 for each instrument; but the use of more than two on the same line where privacy is required is not advised. Any person within ordinary hearing distance can hear the voice calling through the telephone. If a louder call is required one can be furnished for $5.

Telegraph lines will be constructed by the proprietors if desired. The price will vary from $100 to $150 a mile; any good mechanic can construct a line; No. 9 wire costs 8½ cents a pound, 320 pounds to the mile; 34 insulators at 25 cents each; the price of poles and setting varies in every locality; stringing wire $5 per mile; sundries $10 per mile.

Parties leasing the telephones incur no expense beyond the annual rental and the repair of the line wire. On the following pages are extracts from the press and other sources relating to the telephone.

GARDINER G. HUBBARD.

THOS A. WATSON, 109 Court street, Boston.

A FINLAND TELEPHONE LOVE STORY.

Mrs. Alec. Tweedie has recently brought out a book entitled "Through Finland in Carts," full of racy chat of travel. She speaks of Finland as being like Norway "riddled with telephones," and tells the following little story to illustrate the excessive use of the telephone by Finnish folk:

"Pekka was madly in love with Ilma, a wondrously beautiful maiden. He heard rumors that she was trifling with another. He could not stand the torture, even for a few hours, and so rang up the mansion of the family Heikkila.

"Joy. He heard the voice if Ilma in answer and said: 'Is it you, dear one ' 'I, Pekka, am here.'

"A soft sigh replied.

" 'Are you glad to hear Pekka? Do you care for him just a little?'

" 'Yes,' sighed the fair maid.

" 'Darling, it is not true you care for Armas Merikanto?'

" 'No, no,' she cried.

" 'You like me—you love me?'

" 'Yes,' she softly murmured.

" 'Will you be my wife?'

" 'I will, Pekka.'

"Overjoyed, Pekka almost hugged the wooden box that brought him such glad tidings.

" 'When may I come to see you, darling—my little wife?'

" 'Come, Pekka, come for dinner at three o'clock.' A few more sweet nothings, and, quite enraptured, Pekka returned to his office routine. At three o'clock, spick and span, with a golden ring in his pocket, he presented himself at the house of the Heikkilas.

"In the salon stood the mother. He went toward her to receive her motherly congratulations. She rushed forward to meet him, as all good mothers-in-law should, and throwing herself into his arms, she cried—

" 'Take me, Pekka, dearest Pekka; I am yours till death.'

" 'Mine!'

" 'Yes. I have loved you long, darling Pekka, and I am ready whenever you can fix a day for our marriage.'

"Tableau. Moral: Beware of Telephones."

As there are, according to Mrs. Tweedie, some thirty-six thousand more women than men in Finland, the action of Pekka's mother-in-law is explainable.

THE NEW TELEPHONE GIRL.

She was a new girl at the Central Telephone Exchange.

Her previous experience in this big and busy world had been behind the counter at Chintz & Chally's.

Nevertheless, she was a pleasant-spoken young lady, and amiability was written all over her nature.

She had adopted as her motto the touching sentence: "We strive to please," and she honestly tried to live up to it.

There was a ring at the bell.

She applied her ear to the instrument, and asked, sweetly: "What number, please?"

"Let me have No. 474."

"I am sorry that No. 474 is busy now," she replied. "You can have No. 473 or No. 475, if you wish."

The individual at the other end of the wire hung up his receiver, and used language which plainly showed that all efforts to please do not necessarily succeed.—Am. Com. Traveler.

VOL. XXIV. NEW YORK, AUGUST 12, 1897. No. 484

THE SMOKE NUISANCE.

WE are told that about six hundred years ago, when London contained barely 50,000 inhabitants, its citizens petitioned King Edward I. to prohibit the use of "sea coal," and its use was abolished effectively by making its employment a capital offense. The burning of "sea coal" has long since been resumed, and the ancient smoke nuisance is still present to remind us of the persistency of human habit in ancient practices. With the exception of a few horrible examples, such as Pittsburg, Chicago and St. Louis, little was heard of the smoke nuisance, but latterly there has been an increasing demand for a pure atmosphere and the full light of the sun, from quarters where formerly no such complaints were heard, more especially in the East. We are bound to say that personal observation in and about New York appears to warrant fully the indictments which have been brought against the creators of the nuisances complained of. The cropping up of the smoke nuisance in our Eastern cities is, of course, primarily due to the adoption of bituminous coal in place of the anthracite formerly used, and it may be taken for granted that, following a well known economic law, soft coal will continue to be used, and its use will spread as long as the present difference in cost between the two continues to be in favor of the soft coal. The confined area of the anthracite belt and the increased cost of mining it, taken in combination with the constantly increasing area of the bituminous coal beds uncovered leaves little room for doubt on this point. We need only point to the fact that in 1880, the production of coal, in round figures, was, bituminous, 38,000,000 tons; anthracite, 25,000,000 tons. In 1895 the total output of the United States was 172,426,366 long tons; the bituminous output was 120,641,244 tons, while the anthracite production was only 51,785,122 tons. Thus, while within fifteen years the anthracite production has increased twofold, the bituminous coal mined has increased more than threefold. Such being the facts, no surprise need be created by the increasing number of smoky chimneys, even in localities close to the anthracite coal fields. Among these the latest to agitate the subject is the city of Philadelphia, whose Board of Health some time ago called upon the Franklin Institute to co-operate with it in considering ways and means for the abatement of the growing evils of the use of bituminous coal within the city limits. The Institute accepted the invitation and as a preliminary step in its work organized a discussion of the subject in which some of the best authorities in the country took part, and which appears in the last two current numbers of the Institute's Journal. The consensus of opinion of all those who took part in this discussion is, as might have been expected, that smoke can be almost entirely, if not absolutely, prevented by taking suitable precautions. The prime cause of smoke generation being incomplete combustion, it is obvious that by securing proper combustion the desired result can be attained. How to secure this proper combustion was the subject of a variety of recommendations. These all simmer down, of course, to the adoption of a properly constructed boiler furnace, and the proper manipulation of the fuel. The down draft furnace and similar devices and the mechanical stoker were shown to be powerful aids in securing the desired end, but, perhaps, as valuable a suggestion as was made was the reference to the neglect of owners of boilers to provide suitable combustion space when changing over from anthracite to bituminous. As was pointed out by one of the contributors to the discussion, most boiler settings, especially those erected more than four or five years ago, have grates averaging not more than 24 inches below the under side of the boiler shell. This is ample for anthracite burning; but for the combustion of soft coal, which involves two distinct processes, a much greater distance is required in order to prevent the cooling of the hydrocarbon gases against the sides of the comparatively cold boiler, before complete combustion has taken place. By placing the grate not less than 40 inches below the boiler shell, and with careful firing, much of the evil can be overcome. That the mechanical stoker fulfills the almost ideal conditions for burning soft coal was very generally admitted, and as it eliminates the personal equation of the fireman there would seem to be no excuse for a smoky chimney with this remedy at hand.

For those who seek for the prevention of the smoke nuisance by the adoption of oil instead of coal, it may be interesting to know that the limited supply of this fuel in the United States is an effective bar to its general employment for firing purposes, while its present cost, as compared with coal, in the large majority of cases, puts it out of the race.

As regards the legislative steps intended to suppress the smoke nuisance, some advocated a series of graduated fines, but the majority were of the opinion that better and more lasting results could be obtained by educating steam users to a realization that a smoky chimney means loss of fuel and hence just so many dollars and cents out of their pockets. We would like to be of the party of moral suasion, but we are certain that the advocates of this policy have never been domiciled within the noxious area of a soot-belching chimney; if they have they are possessed of more equanimity and charity than falls to the usual lot of man. Vigorous methods have largely prevented the smoke nuisance in St. Louis and Chicago, and soft coal users in other localities would do well to give this matter their attention and to provide voluntarily the smoke-preventing devices which, sooner or later, will be rightfully demanded by the public.

THE TECHNIQUE OF GERRYCIDE.

A PATENT has just been issued to Mr. E. F. Davis on improvements in the apparatus employed for electrocution. It has been generally understood that the apparatus would

stand a great deal of improving, but this seems to be the first patent on the subject. Mr. Davis claims the use of an alternating current machine, whose currents in one direction are stronger than those in the other, and from which therefore a better effect can be obtained in bursting the blood vessels of the criminal in the chair. In addition to this thoughtful arrangement, Mr. Davis has a chair with spring mechanisms attached to it, so that the spasmodic contractions or expansions of the body as the current is thrown on or off can be registered and noted, whether for the muscles of the arm or for any other part of the body. Mr. Davis says that such data has a scientific value, and adds naively that it, "of course, could not be obtained in any other way." The chair also registers the weight of the condemned person sitting in it. Mr. Davis has evidently given the subject his most serious consideration and study, and criminals under sentence of death in New York will be grateful to him not only for the thoroughness with which he enables sentence to be carried out, but for the fact that each case will now furnish scientific data. The patent issued to Mr. Davis is a broad one and well put, but we are under the impression that one or two others exist, in which the expansion of portions of the body of man and the lower animals is registered by closing a circuit and ringing an alarm bell. In a way this would appear to be an anticipation, although the psychological and physiological functions in such phenomena are not readily differentiated in a patent. We shall look for the early publication of some of Mr. Davis' data, showing how high the strapped down criminal jumps in his chair when the disrupting current is let loose on him.

GASOMETERS AS CANNON TARGETS.

WE understand that some very extensive work is to be carried out at Fort Hancock, Sandy Hook, N. J., where thirty-four large buildings will be massed together in formidable defense operations. The area is 250 acres, there will be quarters for 1,000 officers and men, and the emplacements will have fifty guns, 13, 12, 10, 8 and 6-inch. It is evident that such an installation would and should require a large amount of electric light and power, but we are greatly surprised to learn that Gen. Bachellor, U. S. A., who made the plans, has left electricity out of his calculations and that the present specifications call for an illuminating gas plant for indoor and outdoor lighting.

Such a thing must certainly be an oversight or unintentional. It hardly requires one to be an expert in ballistics and fortifications to see that a gasometer is not the most desirable adjunct to a fort exposed as that at Sandy Hook must always be. Not merely is a gasometer a good mark, but the consequences of its explosion, under fire, would be very serious. On the other hand, an electric light plant can be buried, if need be, out of sight as deeply as the powder magazine, and signs of its location would be very hard to discover. Moreover, aside from the value of the electric light on a great many grounds, there are the additional advantages of having a source of current for power purposes. There seems no good reason why a fort should make any less use of electric motors than a battleship, and our men-of-war have won the commendation of foreign experts for their liberal and ingenious equipments of electricity for a wide range of work.

We trust that Fort Hancock when finished will not include a big gasometer as a target for the enemy's guns, but will be furnished with the latest and best electric plant that the money and skill of the Government can buy.

IMPROVEMENTS IN TELEPHONY.

LAST week a fully descriptive article appeared in our pages of a new telephone exchange at Augusta, Ga., where the apparatus is of such a thoroughly automatic type that the "central" office goes on working smoothly even when its doors are locked and there is nobody in it. Commercially considered, this would appear to be a great advance in practical telephony; and the article which we publish this week on a similar exchange at Amsterdam, N. Y., would lead to the conviction that the system is already well within the range of practicability. It is needless to point out the many changes involved in such methods, if generally successful, and finally adopted everywhere, and this evolution will, therefore, be watched with deep interest.

Another feature of novelty, in connection with the telephone exchange at Amsterdam, is the use of bi-metallic wire. The reports of results are very satisfactory, and here again would appear to be an opportunity for getting away from iron wire in telephonic work. It would be difficult to sum up all the damage that has come from the use of the fragile iron wire still so largely in use, and the rapid extension of telephony to-day will only bring with it more accidents and fatalities unless the change is thus made to something of higher conductivity yet better able to stand strains and to resist the effects of time and weather. The indications are that telephone managers constructing aerial circuits are becoming thoroughly alive to the risks they run when using brittle wire; and hence we are likely to see fewer casualties due to broken wires and crossed trolley, lighting and telephone circuits.

PROVE ALL THINGS.

THE X-ray has come into use as an invaluable aid in carrying out the Scriptural injunction to prove all things. It was early suggested to try the ray on mummies, and this has since been done with gratifying results, so that it is no longer necessary to carve up specimens of preserved humanity to see if there is anything inside. The application of the same plan or principle to odd and abnormal beings, or freaks of creation, such as find their way into museums and shows of the Barnum type, is obviously useful and practical. It is said that a Japanese monster brought recently to the Salpetriere Hospital, in Paris, was submitted to the ray. It purported to be the carcass of a mermaid, but it was shown to be without bones and therefore a built-up fraud, very cleverly done. The missing link had, however, too many links missing, and the fishy creature was altogether too fishy. The modern shibboleth of scepticism is, "Ray all things."

WOMEN IN TELEPHONE EXCHANGES.

AT one time there was a very decided prejudice against the employment of women as night operators in telephone exchanges, but it is certainly disappearing. An instance of this is given by the New England Telephone Company, which has just discharged some thirty men who had been doing night work in Boston, and has returned to the use of young women for the hours of night duty. We are glad to see the change made, and believe that the objections to it are far more visionary than real. The electric light, the trolley car and the police signal system have made the streets of our modern cities generally safe at any hour of the night for ordinary passengers, even on foot; and the field for the employment of women has thus been distinctly widened by the introduction of the electrical arts.

WIRELESS telegraphy is occupying a good deal of attention just now, and to accompany the encouraging reports from Mr. Tesla of his advances and success with new apparatus for such work, we note the statement from Marconi that he is about to signal electrically without wires from St. Paul's Cathedral, London, to the Eiffel Tower, in Paris, a distance as the crow flies of perhaps 150 to 200 miles. It will be interesting to see what comes of all this movement which may well betoken a new advance in electrical discovery and invention.

News and Notes

SOME NEW PRINCIPLES IN DYNAMO DESIGN.

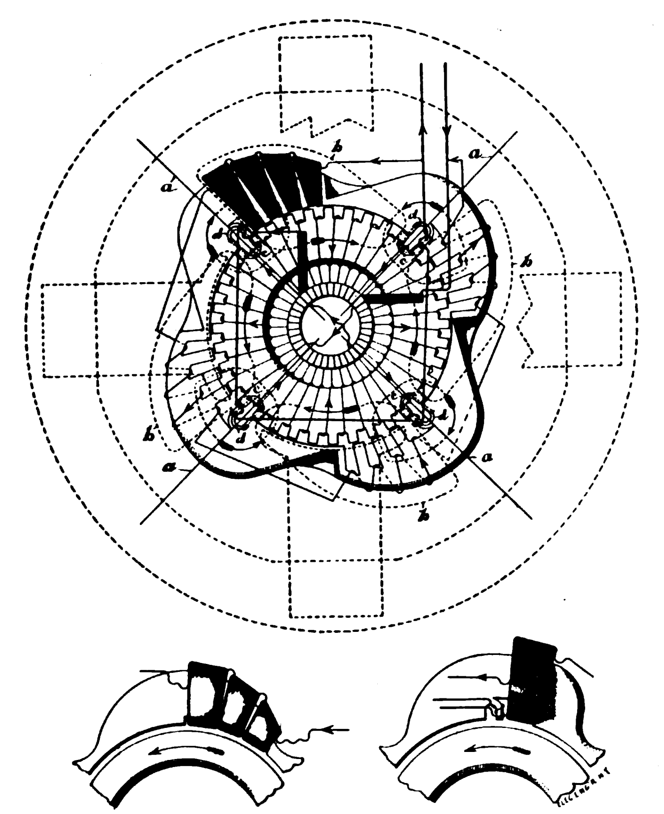
BY ALBERT W. SMITH.

IN the present types of dynamo the field distortion, due to armature reaction, is combatted by the employment either of a large air gap, or oversaturation of the core teeth, or both; the object being to oppose as much reluctance as possible to the magneto motive forces of the armature, and thus resist or limit field distortion due thereto. Unfortunately, however, the reluctance obtained by these means is equally opposed to both the armature and field windings.

These methods, therefore, necessitate the employment of large field coils, which impose the necessity of long magnet cores, which in turn imposes a large and heavy ring or yoke structure.

In spite of the large air gap reluctance, more or less field distortion, according to load, takes place, thus necessitating a forward shifting of the brushes, which, in turn, destroys the balance between the front and back armature turns interlinking with the field flux, thus proportionately weakening the field magnetism, and therefore imposing the necessity of using series or compounding coils, which still further increases the length of the magnet cores, and the amount of magnetizing energy, etc.

All of the above named conditions, therefore, conspire to impose the necessity of using a field magnet structure which is several times heavier than the armature, and which requires a large amount of magnetizing energy, and adds enormously to the weight of the machine per unit of output.



THE SMITH IMPROVED FIELD MAGNET WINDING.

To overcome the above named untoward conditions, it is proposed to displace the field magnet coils rearwardly from the neutral or commutating points, and to wind them in or across the flux paths of their respective magnets, and close to the armature, as shown in the accompanying illustrations.

Argument.—It is obvious that the magnetism generated by any given turn or section of a field coil must pass through that turn or section, though it need not necessarily pass through all of the turns or sections of the coil, but may leak out through the side of the coil adjacent to its own turn or section; it follows, therefore, that the magnetism generated by a field coil cannot be shifted forward further than the width of the coil.

It is then only necessary to wind the coils entirely back of the neutral lines, a a, and as close to the armature as practicable, to insure the desired freedom from field distortion; this is made possible by using a field magnet structure which has on one side of its neutral points a single wide pole, or polar area, and on the other side thereof a plurality of smaller poles, forming between them coil-containing spaces (or instead of plural poles a single large coil space), in which space or spaces the coils are wound, as shown in accompanying diagrams.

By this method of winding the field coils, a long external air path of very great reluctance is opposed to the armature magneto-motive forces, b b, thus obviating the present necessity for a large air gap reluctance; the size of the air gap is, therefore, imposed entirely by mechanical conditions, and can be made very small, while the core teeth can also have the same low reluctance as other parts of the magnetic circuit. The magnets, consequently, requiring only a small fraction of the magnetizing energy now necessary, and the coils being correspondingly smaller, consequently require proportionately less winding space; thus insuring a field magnet structure which has about the same weight as the armature, or somewhat less. The dotted outline shows in contrast the ordinary form of field structure, consisting of cast iron yoke ring with wrought iron cores cast in.

The present method of commutating under the leading pole corners is defective, because the brushes cannot remain in a fixed position, without sacrificing other desirable qualities, and also because it imposes the use of carbon brushes, which cause a considerable waste of energy.

To obviate these defects, it is proposed to entirely prevent the spark causing self-induction, due to the rise or increase of current in the armature coils at the moment when their segments leave the brushes. This is accomplished by interlinking the coils at the moment when their segments leave the brushes—and when tending to produce self-induction causing magneto-motive forces, due to current increase, as represented by arrows, c c,—with counter magneto-motive forces represented by arrows, d d, which, being equal or superior to them in strength, suppress those due to the armature coils, and thus absolutely prevent the existence of any spark causing self-induction in the commutable coils; thus insuring sparkless commutation, and enabling the use of metal brushes, which may be either solid, laminated or of gauze construction, and which remain in a fixed position for all variations of load and speed.

With this method of commutation the coil does not cut a magnetic field at the moment when its segment leaves the brush, as it does in the present used method; the electro-motive force due to self-induction is, therefore, not neutralized or counteracted by an opposing electromotive force, due to the cutting of a field, but is absolutely prevented from coming into existence, by interlinkage of the coil with a field of contrary direction to that which the armature coils tend to set up at the moment when the segment breaks contact with the brush. It will be apparent that the conditions and results obtained with this method of commutation are analogous and equivalent to those which prevail in motor generators having both windings on the same armature. In this type of machine, as is well known, the brushes remain fixed for all conditions of load, and commutation is sparkless and perfect. The absence of field distortion and sparking makes it possible to arbitrarily locate the position of the brushes when designing a machine for any given service, thus enabling any kind or amount of automatic regulation to be obtained by simply determining or fixing the constant ratio or proportion between the front and back armature turns interlinking with the field flux; thus enabling a machine to compensate for drop in engine speed, to have a rising voltage, as for railway work, or to have a falling voltage, as for some kinds of electrolytic work, without the use of any series or compounding coils.

With the present types of dynamo the output of the machine is limited by the current carrying capacity of the armature, and by the sparking at the brushes. The carrying capacity, and, therefore, the output of most armatures in present use, could be greatly increased by a better design of winding, eliminating spiral end connections, etc.

This has not been generally done, for the reason that the present low sparking limit would permit of no material increase in output; the absence, however, of both field distortion and sparking in the present design makes it possible to take full and complete advantage of all available means for increasing the carrying capacity of the armature, and, therefore, makes possible a proportionately greater output or effectiveness from a given size of armature.

The absence of field distortion and sparking also makes it possible to design high voltage direct current machines for power transmission over long distances, thus securing higher efficiency, especially at part load, and lower first cost than is possible with the present used methods.

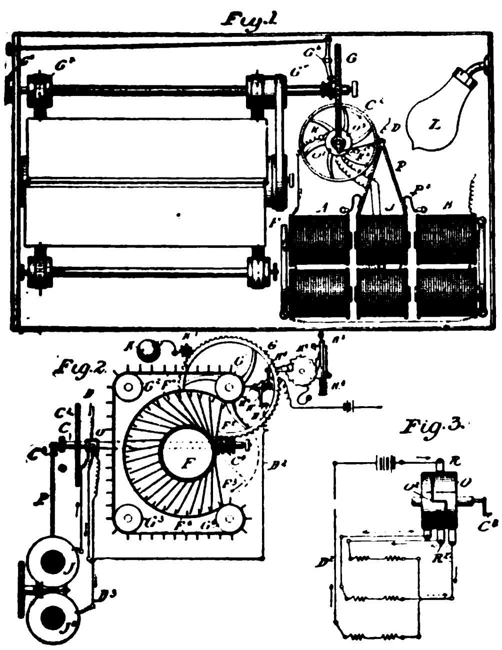
It is sometimes desirable to directly connect dynamos to high speed steam turbines, thus obtaining large output, due to high velocity. While it is possible to do this with dynamos of the present type, much difficulty is experienced, due to the inherent defects of field distortion, and self-induction in the armature coils, all the bad effects of which are greatly aggravated under those conditions, and, therefore, tend to impose a kind of speed limit on the armature.

In the design here proposed, however, this speed limit does not exist, and in so far as difficulty from these sources is concerned, the armature can be run up close to the mechanical or bursting limit, thus making it possible to obtain under these conditions a very large output per unit of weight and also very high electrical efficiency.

COMBINED ANNUNCIATOR AND ADVERTISING CABINET FOR CARS.

MR. GEORGE H. PUGH and Dr. J. P. Orr, of Pittsburg, Pa., have recently designed an apparatus designed to be placed in cars and combining the functions of a street annunciator with an advertising cabinet.

The accompanying illustrations show plan and sectional views of the mechanism, comprising a cylinder, F, having mounted thereon leaves or cards on one side of which is the name of a street or station and on the other side of which is displayed a business card or other advertisement. These cards are controlled by a toothed belt mounted on pulleys G, which have gear connection with and are propelled by an electric motor comprising six helices, four of which are



COMBINED STREET INDICATOR AND ADVERTISING CABINET.

mounted in pairs with space between, and two helices pivotally mounted between the pairs as an electro-magnetic armature, electrically connected with commutator O, which has two peripheral rings with offset portions insulated from each other. These rings in contact with the brushes are connected with the helices of the armature, and the offset portions are in contact with brushes, thus completing circuit through the magnet helices and battery, as shown. The reversed current through the armature, is shown by dotted arrows.

The device is set in motion by an ordinary push button or by a bell rope connection, and stops automatically as soon as a leaf or card swings downward to display the "next stop."

PEORIA, ILL.—Mr. A. N. Morton, local freight agent of the C., P. & St. L. Railroad, is seeking to secure a franchise for an independent telephone company, which eventually should have 4,000 instruments in use.

LETTERS TO THE EDITOR

INTERIOR CONDUIT AND THE FIRE RISK.

IN your issue of July 22 is an article on "The Inconsistency of Plain Iron Interior Conduits," by "Jim Crow.". The writer evidently does not properly conceive the function of iron pipe or iron-armored conduit as viewed from the standpoint of one who has the prevention of fire in mind. High insulation is not necessarily a protection against fire. I have known of lightning discharges breaking through good rubber-covered wire, and a considerable distance of air gap, starting short circuits which caused fire.

An iron-armored or iron conduit, if properly put up, is a protection against fire, even if a short circuit between the wires within the pipe, or a ground on the pipe occurs. The chief difficulty lies in getting contractors to put up this class of work properly. The piping must be electrically continuous and heavily grounded, with a ground of carrying capacity equal to that of the largest wire in the system. All couplings must be tight, and all joints electrically as well as mechanically secure. A single ground occurring in such a system is immediately indicated on the ground detector, and grounds on opposite sides of the line blow the first fuse on the line or lines in trouble. No ground can occur except on the piping system; in short, the armor-conduit stands guard to protect everything else from the wires and the wires from everything else.

Whether plain iron pipes or insulated pipe should be used has been wisely left to the individual engineer to decide, the additional insulation being required either on the wire or in the tube. If it is placed in the tube, we have a reasonable assurance that the tube is smooth on the inside. On the other hand, in pulling a conductor into a tube the strain and abrasion is greatest at the bends. This strain is on a different portion of the wire each instant, but always on the same portion of the tube. Hence, the additional braid should be on the wire. The advantages and disadvantages of placing the insulation in one place or the other thus seem to balance one another. Manufacturers of wire or of conduit should not be allowed to influence the decisions of inspection bureaus, the fairness of whose attitude is demonstrated by the acceptance of both systems.

Where no secure electrical, mechanical or magnetic protector stands guard over the wires, large air spaces and high grade insulators are necessary and are properly insisted on. The main dangers arising from electric wires are due to ignorance or negligence on the part of wiremen more frequently than to defects in the rules. With iron conduit, as with all other systems, slovenly work, poor joints and bad insulation make a dangerous equipment.

WM. MAYO VENABLE,
Inspector Cincinnati Underwriters' Association.
Cincinnati, Ohio.

THE GIANT SEE-SAW.

Noticing that on page 66 of your issue of July 22 you describe and illustrate the Nashville Exposition "See-Saw," mentioning it as unique and newly designed, I beg to call your attention to the fact that I designed an analogous structure. of much larger size, in the year 1891, submitting drawings of the same to the managers of the Chicago Exposition, as a possible structure of interest. It was, however, not built, on account of the large expense involved.

This structure was illustrated at the time in a number of newspapers, notably among them the Scientific American Supplement of May 30, 1891. OBERLIN SMITH.

Bridgeton, N. J., July 28, 1897.

BUTTER MADE ON A STREET CAR.

The dame owners of cows in the vicinity of the packing houses, when the cream is ripe, set the churn on the front end of a car. One round trip and "churnin's done," the motorman taking the buttermilk as an equivalent for the mechanical agitation imparted.—Wichita Eagle, Kansas.

ELECTRIC TRANSPORTATION

THE PYOTT ELECTRIC STREET CAR.

MUCH ingenuity has been displayed in the designing of street railway cars, resulting in making the American car the model for the rest of the world. Yet we are constantly brought face to face with still further improvements, effecting increased capacity and ease for handling passengers and

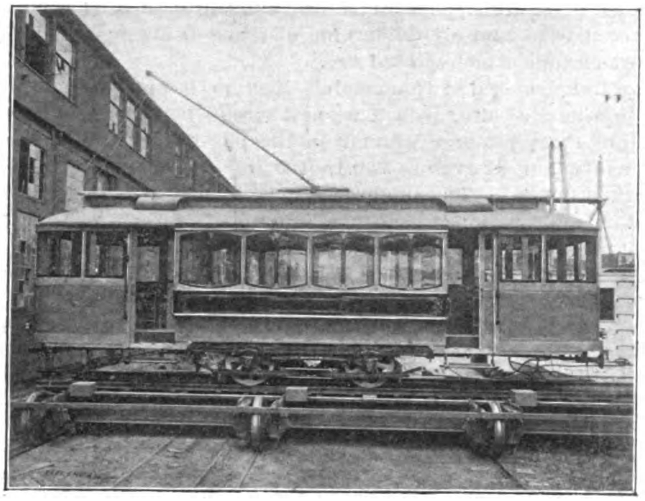


Fig. 1.—Pyott Street Car.

at the same time adding to the comfort of riding. A novel departure embodying a number of striking features in street car building has recently been made by Mr. Louis T. Pyott, of Philadelphia, to whom a number of patents have been issued both on car body and on truck construction. The accompanying illustration, Fig. 1, shows the Pyott car complete on a transfer table, at the works of the Harlan & Hollingsworth Company, of Wilmington, Del., the builders.

The dimensions of the car are as follows:

	Ft.	In.
Extreme length of car over bumpers	33	0
Body length	31	8
Distance between doors	14	6
Body width in center	8	0
Body width in ends	7	0
Spring base	13	0
Wheel base	6	6

The car is equipped with the new "General Electric, 1,000," motor.

A distinguishing feature of the car is the truck, which is shown complete in Fig. 2, and which has been designated as the "companion," or "sectional truck." As will be seen, each pair of wheels and axles has its own independent "horseshoe" frame pivoted and connected with the other, thus permitting each pair of wheels to independently follow the rails in any elevation or depression, without any possible twisting of the framework, or the unseating or heating of the journal bearings, or the rubbing of the axle boxes on the pedestals, thereby reducing the running friction and the twisting of the supported car body to a minimum, and the motor and its supports are in perfect alignment with the same. Fig. 3 shows an enlarged view of one of the "companion" truck frames.

The auxiliary frame or structure beneath the car is evidently adapted particularly to the varying conditions of the

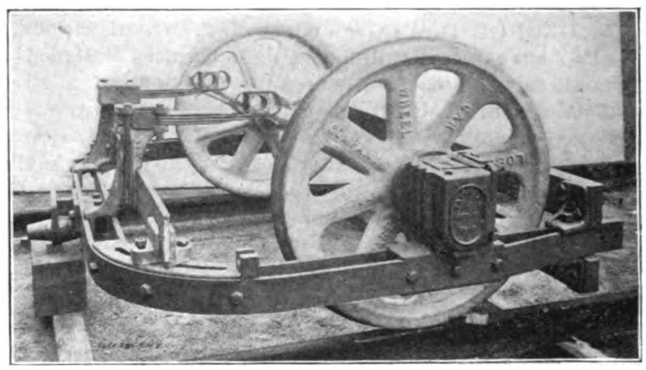

Fig. 3.—One Section of Pyott "Companion" Truck.

cars to be carried, as shown in the fact that in the car illustrated the length of the spring base is 13 feet.

The beam above affords a point of bearing under which is supported a single equalizing beam in connection with the springs, bearing directly on the oil boxes. There is thus secured what steam railroad men term a three-legged support for the car in relation to the rail, avoiding the twisting and

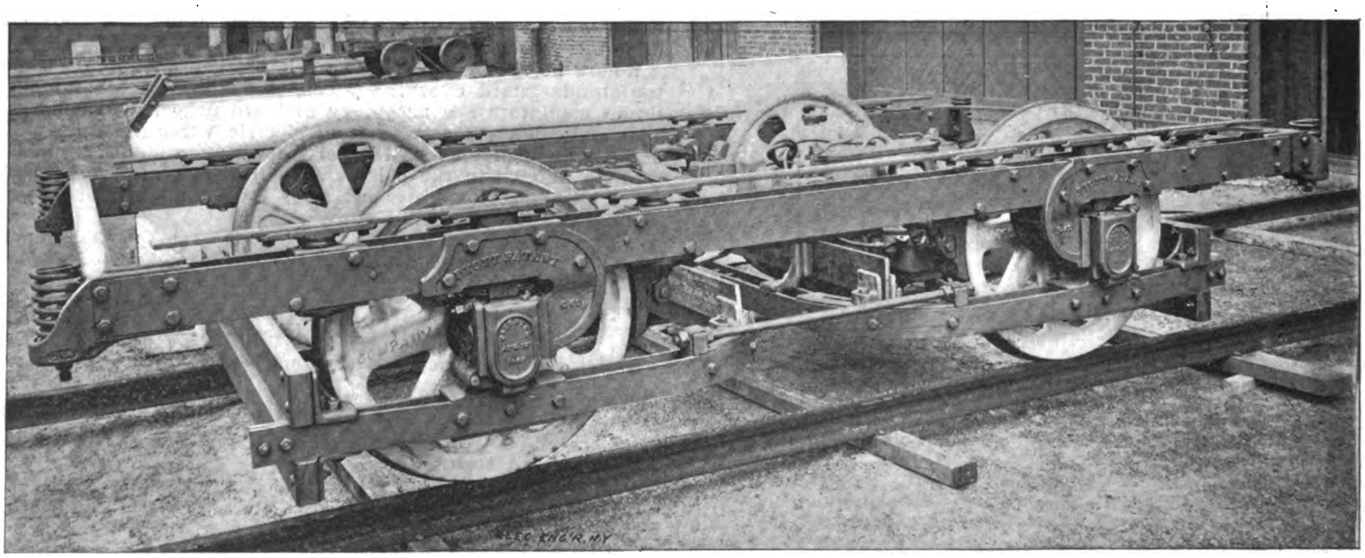

Fig. 2.—Pyott "Companion" Electric Street Car Truck

rocking of the car body usual in four supports, where some one of the four is usually too high or too low. The equalizing beam allows the wheels to move up and down to any irregular alignment of the rails, and when the springs admit of no more action under an excessive load, there is a mechanical action in the lever or beam device itself.

The motor support is at the usual point of a side bar or balance support. An arm spring is in direct connection with the motor casing, dispensing with the usual combination of levers, links and coil springs.

A single-legged pedestal is employed to combine the lower section of the truck and auxiliary frame under the car, thus admitting of the use of a side gap oil box which permits of easy removal of the axles and allows a thorough examination

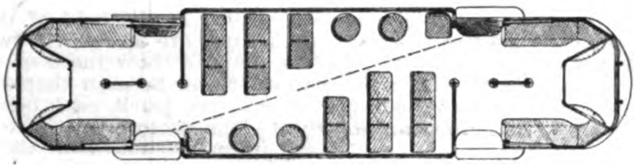

FIG. 4.—SEATING ARRANGEMENT OF PYOTT STREET CAR.

of the condition of the journals to be made in a few minutes. The brake is center hung and very powerful in its action.

Mr. Pyott has given particular attention to the seating arrangements in the car, which has a seating capacity of 38

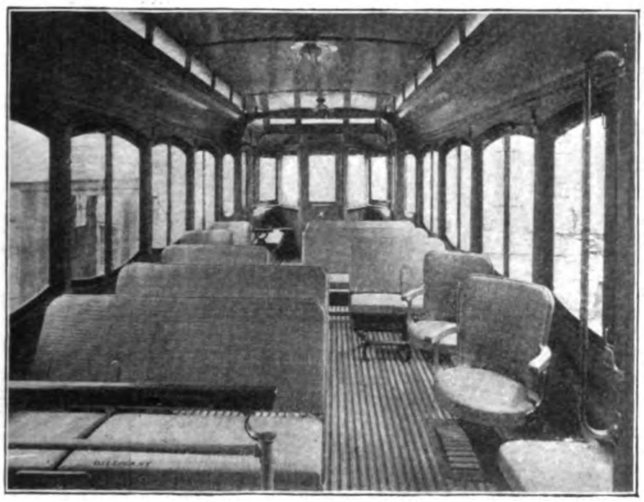

FIG. 5.—INTERIOR VIEW OF PYOTT STREET CAR.

persons, with ample room to carry 100 in all. The layout of the car body is shown in the diagram, Fig. 4, and Fig. 5 gives an interior view of the car. In this method of building a car the usual platforms are entirely dispensed with.

As will be noted the car has two doors on each side, placed about midway between the center of the car and the end. This lessens the amount of travel required on entering or leaving the car, and hence effects a saving in time. The diagonal aisle through the central portion of the body brings a direct line of exit to the rear right-hand door, which is immediately under the eye of the conductor. When running on a single track road all four doors can be used. By dropping the lever or cross-bar at the door the step is raised and the use of the door opening dispensed with, thus rendering it safe when running on a double track road.

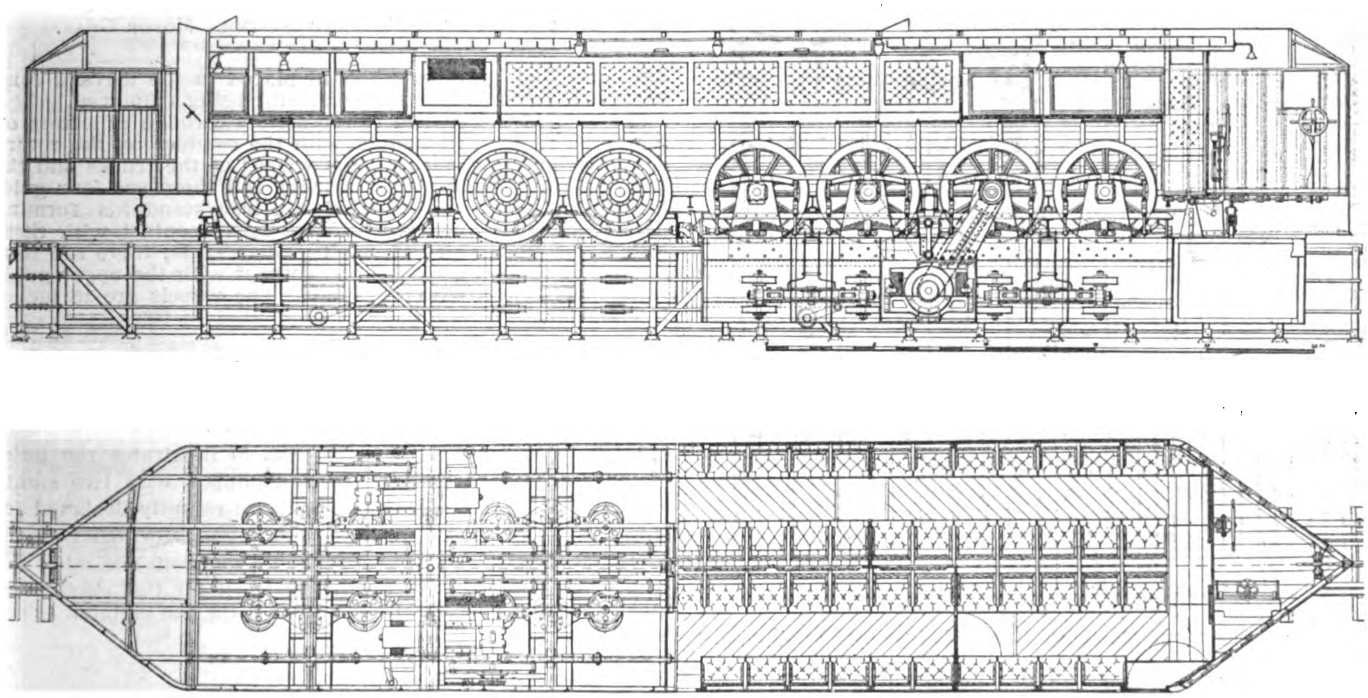
The car is intended for universal use the year round, having movable sashes carried in pockets provided in the car, readily removed and stored in the car, in warm or pleasant weather, and readily removed from their storage place and applied to make a closed car if a storm arises, or in cold weather. The motorman's compartment is arranged to close in rough weather.

From the above description it will be apparent that Mr. Pyott has embodied in his car a number of principles eminently calculated to afford ease and comfort for passengers, and economy for the railway management, as an equipment of these cars answers every purpose of the double equipment of closed and open cars now generally in use.

THE BEHR MONORAIL ELECTRIC RAILWAY.

THERE appears to be a particular fascination among railway engineers of a speculative turn of mind for a single rail system. The latest serious attempt to realize such a system and to solve the problem of very high speed transportation is embodied in the Behr monorail system now in operation in connection with the Brussels Exhibition. The Behr car and track system are shown in the accompanying engravings, taken from "Engineering."

The car is 58 feet long and about 11 feet wide. It is framed entirely of steel. Its bottom edge is 7 inches clear of the sleepers, and the floor level is about 5 feet above, the height of the bearing rail from the sleepers being 4 feet 1½ inches. From the floor or upper deck of the carriage the sides rise so as to give a lofty enclosure for the passengers, and the roof is arched, as shown in the cross-section, Fig. 3. The same figure indicates the transverse form of the carriage, which is made with a deep recess running for its whole length to receive the wheels and trucks on which it is carried. The driving and guiding mechanism is contained in the hold of the carriage, the electric motors being attached to the framing of the lower deck. As is shown in the plan, Fig. 2, the ends of the vehicle are tapered to an edge to reduce the air resist-



FIGS. 1 AND 2.—THE BEHR ELECTRIC HIGH SPEED MONORAIL CAR.—LONGITUDINAL SECTION AND PLAN.

ance when running at high speeds. The capacity of the carriage is 100 passengers, for whom seats are provided in four rows, each passenger being provided with a separate seat,

specially shaped to reduce, as far as possible, the unpleasant effect of centrifugal force when passing over sharp curves at high speed. Internally the carriage is divided into compartments, one of which, 20 feet long by 5 feet 6 inches wide, is reserved for the use of royalty.

The weight of the car is about 55 tons, which is considerably in excess of the designer's intention, the weight originally proposed having been 47 tons. As will be seen from Fig. 3, the roof of the carriage is double, the distance between the outer and inner casings being sufficient to admit of a device for supplying air to the interior of the carriage, without any violent draught. Ventilators are placed on the roof, and air flows through them into the space between the casings, where it is met by a series of baffle plates, that gradually reduce the velocity of the current, until it flows through openings in the inner casing, at a convenient rate. As will be seen from the longitudinal section, Fig. 1, the carriage is lighted by incandescent lamps, taking their current from the main circuit. The triangular chamber in the bow of the carriage is reserved for the driver, who has at his command various devices for controlling the current, manipulating the special air-brakes, and putting on the hand-brakes for bringing the carriage to rest.

One of the original features of the Behr carriage is the arrangement adopted for checking the carriage when running at a higher speed than could be controlled by existing forms of brakes. For this purpose the tapering ends forming the bow of the carriage, are fitted for their whole height with a series of louvre plates turning on vertical spindles, the lower ends of which are extended beneath the floor and carry worm-wheels that gear into a series of worms on a horizontal shaft. These are shown in the longitudinal section, as well as the hand-wheel and bevel gear turning the shaft. By operating this wheel all the louvre boards on each side of the bow are opened more or less at the will of the driver, and air resistances are created by the exposure of the inner sides of the louvres and the side plates of the frame. It is intended that as soon as the speed is reduced to convenient limits by this means, that the stop should be completed by means of the

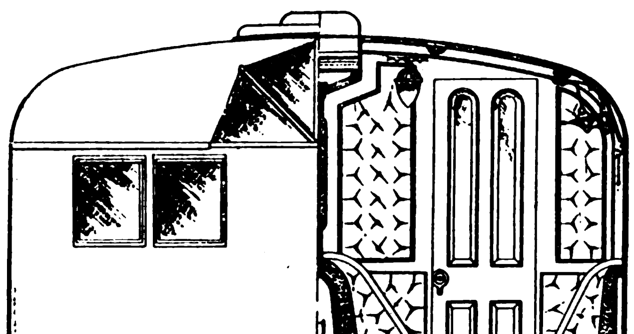


Fig. 3.—The Behr Monorail Car.—Transverse Section.

hand-brakes, which can be applied to each wheel of the carriage; the position and method of hanging these brakes is indicated in the longitudinal section, Fig. 1.

The carriage is supported by eight wheels, 4 feet 6 inches in diameter, mounted in two four-wheeled trucks which are coupled at the center by means of a universal joint. The very short axles of the wheels run in boxes mounted on pedestals that are riveted to the main frame, and the carriage is hung on the boxes by means of cast steel curved hangers to springs, one on each side of the wheels, the springs being beneath the axles. The general arrangement is shown in the section and plan, Figs. 2 and 3.

There are four electric motors, placed in the hold of the carriage. Thus two wheels of each truck are driven, the two outer wheels running free. Figs. 2 and 3 show the disposition clearly, and from these figures it will be seen that the motors are placed on opposite sides of the truck, each being coupled to an independent wheel. The motors are of the four-pole type, with toothed armatures wound with Eickmeyer coils. Each motor is designed for developing 150 h. p., when furnished with a 700-volt current and running at a speed of 600 revolutions per minute. As will be seen, the motors are bolted to the lower deck of the carriage, and a rigid distance-piece, Fig. 4, connects the motor shaft with the axle of the driven wheel, the speeds of each being equal. The means of transmission is a Renold steel chain, which appears to have given satisfactory results when tested. The motors

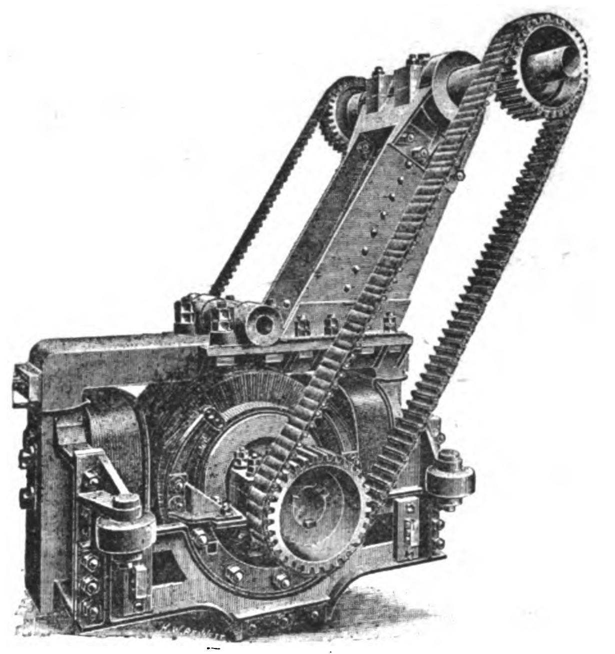

Fig. 4.—The Behr Monorail System. Motor Gear.

are controlled by a switchboard placed in the driver's compartment, the multiple series control being employed.

The current is supplied to the motors through collectors on the carriage, kept in contact with the conductors, the return circuit being made through the wheels of the trucks and the carrying rail. Besides this carrying rail there are four guiding rails, two on each side of the iron standards forming part of the permanent way. Working in contact with these rails are sixteen pairs of small guide wheels; there are thus sixteen of these wheels kept in contact with the upper guide rails, and sixteen with the lower. The wheels are 18 inches in diameter.

ELECTRICITY AS A MOTIVE POWER ON ELEVATED RAILWAYS.—II.

BY PROF. S. H. SHORT.

THE accompanying diagram (Fig. 5) illustrates the Baldwin standard elevated truck equipped with two standard 200 h. p. L motors, which we have recently designed for this work. These will operate a standard elevated train of three cars, fully loaded, at a schedule speed of 16½ miles per hour. We give also the train data sheet for this equipment, and speed and horizontal effort curves for the motors. (Figs. 6 and 7.)

ELEKTRISCHE BELEUCHTUNGSANLAGEN.—(Electric Light Plants.) By F. Gruenwald. Sixth Edition. Halle a. S. 1896. W. Knapp. 1896. 308 pp. Pocket size. Flexible cover. Price, $1.00.

This work is intended as a guide for those engaged in the erection, operation and repair of electric light plants. The author takes up the various parts of such plants in detail, beginning with the engine and ending, one might say, with the last lamp on the system. Every apparatus met with is thoroughly described, and its operation is clearly set forth. We note quite a number of little wrinkles and details of construction, as well as types of fittings, etc., which might be profitably brought to the attention of American manufacturers and workmen.

AMERICAN STREET RAILWAY INVESTMENTS.—A Supplement to the Street Railway Journal. The Street Railway Journal Publishing Company. 1897. 290 pp. 9½ x 13.

This excellent work includes as usual a tabular presentation of gross receipts, operating expenses and balance sheets for from three to five years of over twelve hundred street railway companies in the United States and Canada. It is interesting to note that of the 1,262 reporting, 939 are operat-

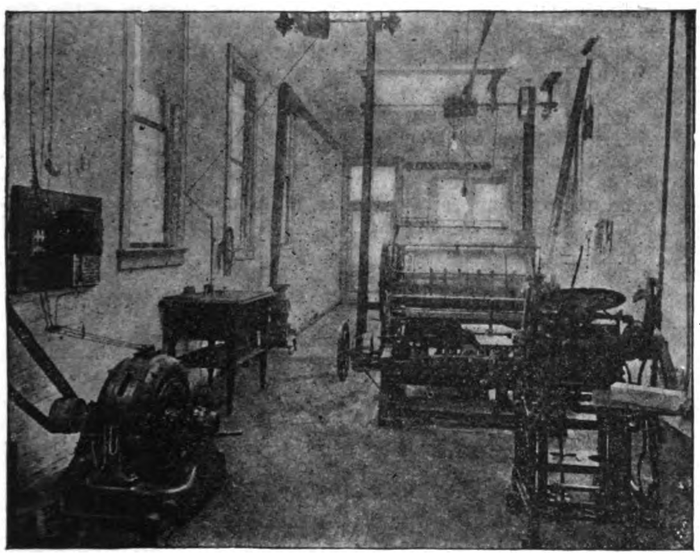
ing companies, 206 are leased companies and 117 are not yet in operation, but with their roads under construction. The "Review of the Year" gives a brief exposition of the principal street railway events during the past year. We also notice a table of "Gross Receipts" in 1895 and 1896, showing the percentage increase or decrease in receipts for every system whose gross receipts exceed $25,000. A number of new maps have been added which add considerably to the value of this excellent work.

POWER TRANSMISSION

ELECTRIC POWER IN SACRAMENTO, CAL.

THE electrification of Sacramento is proceeding apace since the introduction of the current generated at Folsom, twenty-four miles away, demonstrated the cheapness of electrical power when compared with steam power. Electricity is now used in Sacramento to drive machinery of all kinds, and is entering largely into what may be called the household life of the city. One of the most important motor installations is that driving the machinery in the shops of the Southern Pacific Railway Company, recently described in these pages. At about the time this was effected the Buffalo Brewing Company, of Sacramento, substituted motors for the steam engines upon which it had previously been dependent for power, with gratifying results.

This brewery is one of the largest on the Pacific Coast. Its present motor equipment consists of one 5 h. p., one 10 h. p.



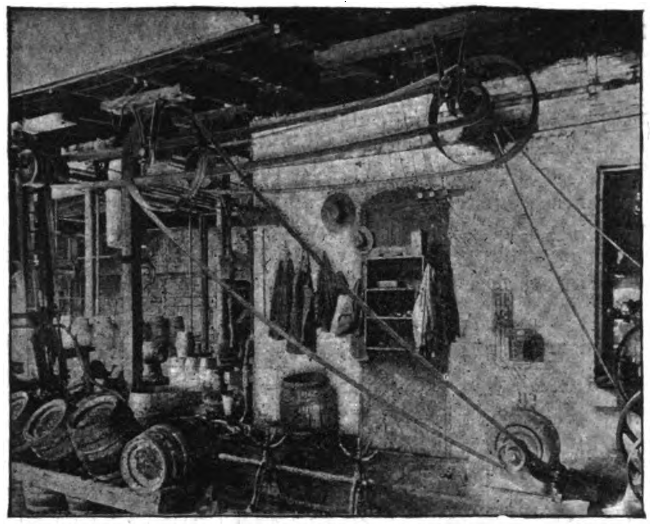
A SACRAMENTO PRINTING OFFICE RUN BY POWER FROM FOLSOM, 24 MILES AWAY.

and one 20 h. p., and two 30 h. p. motors. They are all of the General Electric Company's three-phase induction type, without brushes, collector rings or moving contacts, and run almost without attention beyond an occasional oiling. They are driven by 220-volt current supplied from the 1,000-volt circuit, running from the substation, a distance of two miles, the pressure being transformed down at the brewery.

The smallest motor is used in the bottle-washing house, that of 10 h. p., in the keg-washing department. The three others are used to operate the blowers, the malting house and the machine shops. The large ammonia pumps in the brewery will also shortly be driven by electric motors.

The printing presses of Day & Joy, in Sacramento, are also driven by motor. In this case the motor is of similar type to those in the brewery, but of 10 h. p. capacity. It was one of the first in the city to take current from the long distance transmission. On the day of its installation, the 8 h. p. engine, formerly used, was draped in crape. Its usefulness had departed, with its noise, heat and discomfort. The motor now drives one four-roller Huber cylinder press, one Cottrell press and two job presses, and although it has been in use a number of months has not involved the firm in a cent for repairs.

In installing the Buffalo Brewing Company motors, the question of the probable economy of the change was naturally uppermost. Would it pay to dispense with steam and trust to the motors? The guarantee finally given was, that electricity would show a saving of 40 per cent. After the



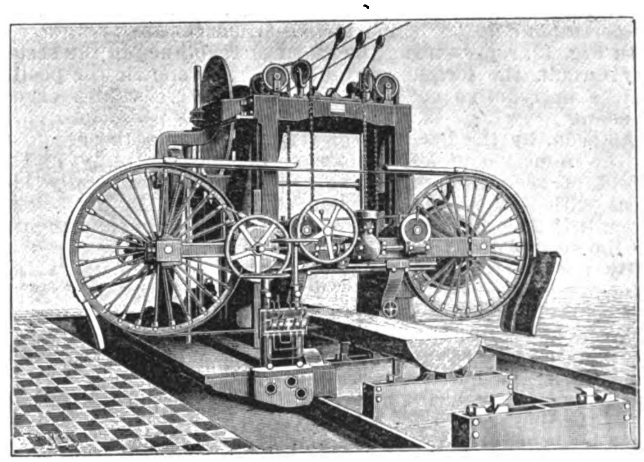
ELECTRIC MOTOR IN SACRAMENTO BREWERY.

motors had been running for some time, a series of tests were made, with the result that the saving instead of 40 per cent. was shown to be actually a little over 50 per cent. Results almost similar have been obtained in other installations in Sacramento. It is hardly a matter of surprise that with such showings to do missionary work, the use of electricity is rapidly extending in that city.

OERLIKON ELECTRIC BAND SAW.

THE Oerlikon Machine Works, Switzerland, have recently constructed a horizontal band saw driven by electric motor, an illustration of which is given in the accompanying engraving, taken from "La Nature." This saw is capable of handling logs up to 1.4 metres (55 inches) in diameter. This new machine consists of a base on which rest the rails and cross-beams to which the logs are fixed and held stationary. The saw is lowered for each cut, the pulleys over which the band saw passes being attached to a cross-head, which can be raised and lowered.

The pulleys are driven by an electric motor of 16 h. p.,



ELECTRIC BAND SAW.

which is shown connected to the pulley at the right-hand side. A simple movement of a lever suffices to raise or lower the saw pulleys.

The band saw travels at a speed of 38 metres per second. The minimum speed of cutting is 34 inches per minute, and the maximum cutting speed is 46 feet per minute. The saw

frame is traversed by a 6 h. p. electric motor. The saw is able to do an enormous amount of work, as several logs can be sawed at the same time. A characteristic of the machine is that the log remains fixed while the saw and the entire superstructure is traversed on rails, the current being taken off by the trolleys shown, and the three-phase current being employed.

THE ALTERNATING CURRENT INDUCTION MOTOR.—III.

BY CHAS. PROTEUS STEINMETZ.

(Concluded.)

FIGS. 12 and 13 give the starting torque, current and torque efficiencies at various resistances and reactances in the secondary and in the primary. In Fig. 12 is gives, with additional armature resistance, R, as abscissæ, the values of starting torque, starting current, power factor, torque efficiency and apparent torque efficiency. In Fig. 13 are given the corresponding values, with reactance inserted in the secondary.

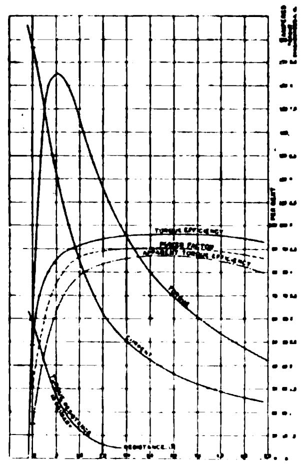


Fig. 12.—Induction Motor. Starting Torque, Current, Efficiencies and Power Factor. $Y = .01 + .1j$. $Z = 1 - .8j$. Resistance in [illegible]

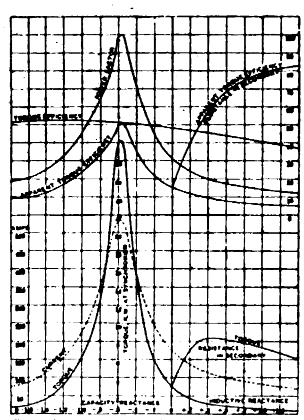

Fig. 13.—Induction Motor. Starting Torque, Current, Efficiencies and Power Factor. $Y = .01 + .1j$. $Z = .1 - .8j$. Reactance in Armature.

FIGS. 12 AND 13.

The insertion of resistance or reactance in the primary has only the effect of decreasing the voltage at the motor terminals and thereby decreasing the torque in proportion to the square of the voltage at the motor terminals, and the apparent torque efficiency directly proportional to the voltage at the motor terminals; that is, is a very inefficient and unsatisfactory means of starting, and suitable by its simplicity only where no starting torque is required, to limit the starting current. By the use of additional resistance in the armature or secondary in starting, torque can be produced, as seen, with the same current power factor, and torque efficiencies as correspond to the same torque when running.

In Fig. 13, representing the effect of reactance in the secondary circuit, the torque, current, etc., are shown for positive values or reactive coils, as well as negative values or condensers.

As seen, by the insertion of reactive coils in the secondary of the induction motor, the torque decreases rapidly, and the effect of secondary inductive reactance is practically identical with that of the insertion of reactance in the primary circuit; that is, the use of inductive reactance in the armature, or the secondary is of no practical value.

By the insertion of negative reactance or capacity, however, torque and current of the motor rise enormously, reaching a maximum of 30,200 synchronous watts and 530 amperes at —.58 ohm additional capacity reactance; that is, 3.66 times the maximum torque available with armature resistance, at 4.22 times the current corresponding thereto. At this point the power factor is 100 per cent.; that is, the current in phase with the impressed e. m. f. On one side of this point the current leads, on the other it lags. Torque efficiency, however, and apparent torque efficiency with the use of capacity in the secondary are very low, the torque efficiency in the whole range being about 50 per cent., while by the use of resistance in the armature a torque efficiency considerably above 90 per cent. is reached. That means, capacity in the secondary, outside of the general inconvenience of the condenser, is far inferior in starting, to the use of non-inductive resistance, except in so far as the maximum available torque is far larger. But the current corresponding to this torque is far beyond the carrying capacity of the motor.

Regulation and Stability.—When operated under these conditions of practice, the induction motor does not give the same margin of overload as when operated at constant impressed voltage. This at once shows the desirability of designing the induction motor with sufficiently large margin of overload, and the necessity of choosing the supply circuit, and especially the transformers, of as low impedance as possible.

As an instance are shown in Figs. 14 and 15, the load curves of the motor discussed in the preceding, rated at 5,000 watts per circuit full load, corresponding to 59 amperes at 110 volts impressed, when operated: (1) At constant impressed voltage of 110 volts. (Fig. 3.) (2) Operated from transformers of 2 per cent. resistance drop and 4 per cent. internal reactance; that is, transformers representing about the best make on the market, of very close regulation. (Fig. 14.) (3) Operated from transformers of 2 per cent. resistance drop and 15 per cent. internal reactance, or about the average type of cheap transformers, at constant primary voltage corresponding to 110 volts at full load at the motor terminals. (Fig. 15.)

In Figs. 14 and 15, the load curves of the motor, the limits of speed and torque curve at constant voltage of 110 are plotted also, showing that the maximum output is reduced under these conditions from 7,000 watts per circuit to 6,450 and 5,780 watts, respectively, and the maximum torque from 8,250 synchronous watts to 7,500 and 6,460, respectively. In consequence thereof, with transformers of poor regulation the motor is at full load already dangerously near the maximum output point, although at constant impressed voltage it has ample margin to carry any reasonable overload.

Still greater is the decrease of voltage, and thus of torque, in starting, especially with low resistance armature, due to the large currents consumed under these circumstances. With an armature containing a variable resistance of sufficient size, limiting the starting current, the starting torque is less affected by the transformer.

If in the installation of the motor the mistake is made not to allow for the drop of voltage taking place even in the best transformers on inductive load, but the ratio of transformation is chosen so as to give the rated motor voltage at the secondary terminals of the transformers at open circuit, output and torque of the motor are still further reduced, and even with the best transformers the margin of overload is only 19.4 per cent. in power and 31 per cent. in torque, while with transformers of poor regulation no margin of torque is left, and the motor cannot carry full load any more. That is, at constant primary voltage corresponding to the rated motor voltage at open circuit at the secondary terminals, the motor can be operated successfully only with the best type of transformers. This fundamental importance of transformer and

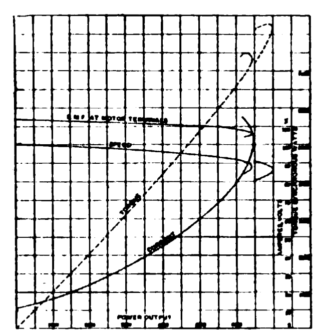

Fig. 14.—Induction Motor. Load Curves. $Y = .01 + .1j$. $Z = .1 - .8j$. Operated from transformers of impedance, $Z = .04 - .08j$, at constant primary potential of 114.1 volts, corresponding to 110 volts at motor terminals at 5000 watts load.

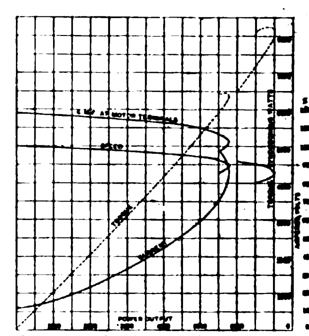

Fig. 15.—Induction Motor. Load Curves. $Y = .01 + .1j$. $Z = .1 - .8j$. Operated from transformers of impedance, $Z = .04 - .3j$, at constant primary potential of 121 volts, corresponding to 110 volts at motor terminals at 5000 watts load.

FIGS. 14 AND 15.

line impedance on the operation of the induction motor has frequently been overlooked. It is, however, analogous to the dropping of torque and output of a continuous current motor, if the impressed voltage drops.

OBITUARY

JAMES W. McDONOUGH.

The death is announced, at Chicago, of J. W. McDonough, who was one of the early claimants for priority in the invention of the telephone, and who had apparently worked out some make-and-break apparatus of

the Reis type. He had been a furniture manufacturer in Chicago, but in 1881 came to New York City, where he acted as electrician for the United States Telephone Company, and for the Schuyler Electric Light Company. He is said to have experimented at that time on various methods of vacuum tube lighting, used both exhausted bulbs and tubes containing carbon dust. He also worked at multiple telephony and for many years, particularly the last twelve, devoted his energies to inventions for photographing in colors.

MR. R. W. LOWBER died last week at his home, Bald Mountain, Washington County, N. Y., aged 72. He is supposed to be the last survivor of the promoters of the New York, Newfoundland and London Telegraph Company, of which he was secretary in 1854.

SOCIETY & CLUB NOTES

FIRE AND POLICE TELEGRAPHERS CONVENTION.

Superintendent Frank C. Mason, of the Brooklyn Police Telegraph, as president of the International Association of Fire and Police Telegraph Superintendents, has issued a call for the annual convention to be held at Nashville, Tenn., on September 14 and 15 next. Two papers of interest to the members will be read during the convention. They will be "Modern Construction and Maintenance of Wires for Municipalities," by William Brophy, of Boston, Mass., and "Storage Batteries and Switchboards as Applied to Fire and Police Work," by J. W. Aydon, of Wilmington, Del. The Old-Time Telegraphers and the United States Military Telegraph Corps will meet in Nashville at the same time.

LEGAL NOTES

MULTIPLE SERIES SYSTEM OF WIRING FOR CAR HEATERS.

We will be glad to have you print the following in your next issue of The Electrical Engineer: "On August 2, Judge Wheeler, of the United States Circuit Court for the Second Circuit, rendered a decision in favor of the defendant in the case of the Burton Electric Company against the Union Railway, of New York, which was defended by the Consolidated Car-Heating Company. This decision settles the right of the Consolidated Company to use the Multiple Series System of Wiring with their electric heaters, and is a decided victory."

CONSOLIDATED CAR-HEATING COMPANY,
F. W. Kelley, Assistant Treasurer.

Albany, N. Y., August 7, 1897.

CONTRACT FOR CURRENT.

The United Electric Light and Power Company, of New York City, contracted with Charles Brenneman to supply light and electric power for fans for the latter's store and restaurant in East Houston street. The contract provided that the consumer should be liable, at a specified rate, as "stipulated damages" for the entire unexpired term of the contract period, in case he "prevents" the company "from supplying the current." Last November Brenneman discontinued the use of electricity for an interval while waiting for a tenant, having determined to go out of the business. Then the company cut out the connection, and brought suit to recover the stipulated damages of $210. The Appellate Term has reversed judgment given in a district court in favor of plaintiff, holding that such liability does not arise where the company cut off the current because it found the premises closed and in partial disuse for a short period.

THREE CENT FARE CASE IN INDIANAPOLIS.

The citizens of Indianapolis are not to have 3-cent street car fares for some time to come. In spite of the decision of the Supreme Court of Indiana holding that the act to reduce fares is not special legislation, and therefore not in conflict with the State constitution, Judge Showalter, of the United States Circuit Court, sustained recently the injunction against the enforcement of the act granted by him some months ago.

In the first place the judge denies that the decision of the Supreme Court of the State is final in this case, because there is a Federal question involved—that the controversy is not merely whether the act in relation to street car fares is special legislation under the Indiana constitution, but whether it is in violation of a contract.

Where a contract is involved, states the judge, and the meaning of it depends on the construction of a State statute or constitution, a decision by the Supreme Court of that State, made after rights have arisen under the contract, is not final, but is reviewable by the Supreme Court of the United States.

VACATING A TROLLEY METHOD INJUNCTION IN NEW YORK CITY.

An order signed by Judge Lacombe was handed down in New York City, in the U. S. Circuit Court, on July 29, vacating the injunction obtained by the Thomson-Houston Electric Company restraining the Union Railway Company, commonly known as the "Huckleberry" Road, and the New York, Elmsford and White Plains Railway Company from using a certain trolley device.

The Thomson-Houston Company claimed to own a patent for the device. The order vacating the injunction is based on the decision of the U. S. Circuit Court of Appeals in the case of the Hoosick Railway Company, of Massachusetts, on July 21, printed in these pages two weeks ago.

CARBON SCREW BATTERY CONNECTORS.

Last January the Phoenix Carbon Company, of St. Louis, bought from the Law Battery Company, of New Jersey, U. S. patent No. 500,284, covering a carbon screw connector for all galvanic battery cells. Holding that this patent was being infringed by the National Carbon Company, of Cleveland, and others, the Phoenix Company brought suit in the United States Court, Eastern District of Ohio, and asked for a restraining injunction. This was granted on June 29, and the Phoenix Company inform us that they are now pressing their suit to obtain judgment. The Phoenix Company say that they will certainly not only stop the National Carbon Company, but any other parties from infringing, and that they will be prepared in a very short time to supply the entire trade with this type, as well as all other types of galvanic batteries. They have enlarged their factory and are filling orders for complete batteries or any battery parts.

REPORTS OF COMPANIES

BOSTON ELECTRIC LIGHT.

The annual report of the Boston Electric Light Company for the year ending June 30 is issued:

	1897.	1896.
Gross income	$759,643	$660,973
Operating expenses	485,498	420,641
Profits	$274,144	$240,331
Interest charges	63,242	50,319
Net for stock	$218,644	$190,012
Dividends	110,500	136,000
Surplus	$108,144	$54,012

THE AFFAIRS OF E. S. GREELEY & CO.

Judge Simeon E. Baldwin, of the Supreme Court, New Haven, Conn., on August 4, sitting as a judge of the Superior Court, signed an order for a hearing on an application of Edwin S. Greeley, receiver of E. S. Greeley & Co., the Dey street electrical supply manufacturers, to sell the uncollected claims of the insolvent concern at public auction, and to pay a dividend on the claims allowed against the corporation. A hearing on the application has been set down for August 16 next. The uncollected bills of the company amount to $15,000. Application has been made to the United States Circuit Court of the Southern District of New York for the removal of the

case to the Superior Court of this county. If this move is successful it is expected that the affairs of the company will be wound up in a few weeks; if not, it is stated that the litigation will be continued for a long time. The amount of the dividend which the receiver is prepared to pay has not yet been announced.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUGUST 3, 1897.

Alarms and Signals:—

ELECTRIC SIGNAL DEVICE FOR ELEVATORS. Otto Raacke and Gustav Hensel, St. Louis, Mo., 587,507. Filed March 11, 1897.
Means whereby an alarm is sounded only on the downward approach of the elevator.

ELECTRIC SIGNAL BOX. Albert T. Whittlesey and Fred. B. Dodge, Cleveland, O., 587,565. Filed June 18, 1896.
Details of construction.

AUTOMATIC SWITCH MECHANISM. Jas. E. Tryon, Detroit, Mich., 587,625. Filed Feb. 23, 1897.
An attachment for fire alarm systems.

BURGLAR-ALARM SYSTEM. Wm. T. Arnold, Chicago, Ill., 587,-669. Filed Dec. 15, 1896.
Means for automatically testing the condition of the protecting-circuits.

Conductors, Conduits and Insulators:—

ELECTRIC WIRE HOLDER. Chas. J. Stram, Waterman, Ill., 587,-614. Filed May 27, 1897.
Consists of a piece of rubber provided with an opening and a support for the holder having embracing tongues and a supporting lip.

Distribution:—

OPERATING ALTERNATING MOTORS. Chas. P. Steinmetz, Lynn, Mass., 587,340. Filed Nov. 23, 1893.
Comprises a combination of circuits with a plurality of motors fed from the same source of power supply, whereby they are adapted to run at a speed below that which either one would have if connected directly into the supply circuit.

REGULATING APPARATUS FOR ELECTRICALLY DRIVEN MECHANISM. Walter H. Knight, Newton and Wm. B. Potter, of Lynn, Mass., 587,441. Filed May 21, 1892.
Means by which two driving-motors may be changed from series to multiple connection.

METHOD OF REGULATING ELECTRICALLY DRIVEN MECHANISM. Walter H. Knight, Newton, Mass., and Wm. B. Potter, Lynn, Mass., 587,442. Filed May 21, 1892.
Similar to above.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. Ernest P. Warner and Henry H. Wait, Chicago, Ill., 587,379. Filed June 3, 1896.
The inner face of the pole pieces are slotted to obviate the formation of a local magnetic field.

ELECTRIC MOTOR OR DYNAMO ELECTRIC MACHINE. Robert Lundell, Brooklyn, N. Y., 587,531. Filed Dec. 15, 1896.
The field coils are removable without disturbing the field magnet.

DYNAMO ELECTRIC MACHINE. Valere A. Fynn, Erith, England, 587,573. Filed Aug. 3, 1896.
Comprises an armature composed of two laminated rings and a field magnet having its two sets of poles arranged alternately in different planes transversely to the shaft, the poles of the same polarity acting upon the same armature ring.

DYNAMO ELECTRIC MACHINE. Chas. M. Green, Cleveland, O., 587,576. Filed Nov. 10, 1896.
Comprises a series of commutator rings, armature coils connected with commutator segments at the same side of the armature at which the coils are located, and several sets of commutator brushes to engage the commutator rings.

Electro-Metallurgy:—

COATING METALS BY ELECTROLYSIS. (Reissued). Hans Alexander, Berlin, Germany, 11,624. Filed July 14, 1896.
A heated bath composed of a solution of commercial chlorid of aluminium containing free acid, and chlorid of the coating metal in suitable proportions.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. S. Bergmann and E. Lavens, Brooklyn, N. Y., 587,421. Filed Feb. 7, 1896.
Embodies an inner globe closed at the bottom and having an aperture at the top, and a cap for the aperture.

ELECTRIC ARC LAMP. Edwin F. Taylor, West Chester, Pa., 587,-465. Filed March 18, 1896.
Comprises a cylindrical casing secured to the base of the lamp-frame, a chimney fitting in the casing and secured to the feedrod of the upper carbon and a restricted opening in the top of the chimney.

Miscellaneous:—

ELECTRIC FURNACE. Geo. S. Strong, New York, N. Y., 587,343. Filed Jan. 20, 1896.
Consists in forming electrodes of a mass of material including a material which will bind the mass together under pressure and supplying the current and pressure simultaneously.

ELECTROTHERAPEUTIC APPARATUS. Fred. Geiger, Philadelphia, Pa., 587,436. Filed May 13, 1897.
Apparatus for utilizing commercial currents for electrotherapeutic purposes.

APPARATUS FOR MANUFACTURING CHLORATE OF POTASH BY ELECTROLYSIS. Ferdinand Hurter, Liverpool, England, 587,437. Filed May 8, 1897.
Employs a cathode consisting of a metallic vessel having a porous protective lining.

PROCESS OF AND APPARATUS FOR MAKING METALLIC CARBIDS. Isaiah L. Roberts, Brooklyn, N. Y., 587,509. Filed June 20, 1896.
Consists in moving beneath a horizontal electric arc the metallic compound and carbon to be converted, and in deflecting the arc downward.

ELECTROCUTION CHAIR. Edwin F. Davis, West Caton, N. Y., 587,649. Filed Jan. 6, 1897.
A chair, having means for registering the changes in physical condition of the body of one sitting in the chair and under the influence of an electric current.

DEVICE FOR INSURING CLOSING OF WINDOWS, ETC. H. I. Surye and M. H. Lewis, New York, N. Y., 587,591. Filed March 25, 1897.
Details of construction.

APPARATUS FOR PRODUCING THERMAL RESULTS. H. Sanche, Detroit, Mich., 587,612. Filed May 29, 1890.
Consists of a metallic cylinder connected at one end to a contact plate by a wire cable.

ELECTROLYTIC HEATING APPARATUS. Geo. D. Burton, Boston, Mass., 587,568. Filed Feb. 24, 1897.
Soldering apparatus.

ELECTRIC BALE-TIE MACHINE. W. O. Bates and W. J. Hutchins, Joliet, Ill., 587,296. Filed March 8, 1897.
Details of construction.

Railways and Appliances:—

ELECTRICAL ALARM FOR CARS. A. Nathan, New York, N. Y., 587,534. Filed June 8, 1897.
Operated by batteries, the circuit being closed by discs placed on the shaft of the controller.

ELECTRIC CONTACT. Arthur J. Moxham, Lorain, O., 587,594. Filed Jan. 28, 1897.
A contact box comprising a metallic cover-plate having a perforation and upward projections on each side, the contact being secured in the perforation, but insulated from the projections.

ELECTRIC CONTACT BOX. Wm. Milton Brown, Johnstown, Pa., 587,642. Filed Sept. 30, 1896.
Switching mechanism for contact boxes.

ELECTRIC RAILWAY. Rudolph M. Hunter, Philadelphia, Pa., 587,-674. Filed July 14, 1885.
Sectional conduit system. Details of construction.

Regulation:—

REGULATING ADMISSION OF CURRENTS TO MOTORS. F. E. Herdman, Winnetka, Ill., 587,311. Filed Nov. 27, 1896.
Consists of a centrifugal governor driven by the motor, opreating a device for increasing the current in the armature.

Switches, Cut-Outs, Etc.

ELECTRIC SWITCH. H. W. Smith, Pittsfield, Mass., 587,458. Filed May 5, 1897.
Electric switch terminal.

Telegraphs:—

TELEGRAPHY. Franc Morrison Short, Cleveland, O., 587,336. Filed April 9, 1896.
Means for transmitting fac-simile messages, designs, etc.

TELAUTOGRAPH. Geo. S. Tiffany, Highland Park, Ill., 587,663. Filed June 7, 1895.
Details of construction.

Telephones:—

SIGNAL FOR TELEPHONE SWITCHBOARDS. Chas. E. Scribner, Chicago, Ill., 587,405. Filed Aug. 1, 1895.
Designed to indicate continuously to the attendant the condition of the apparatus at each of two connected substations.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 587,406. Filed Dec. 18, 1896.
Line signal for switchboards. Details of construction.

ELECTRIC SIGNALING APPARATUS. Mortimer Du Perow, Washington, Dist. of Columbia, 587,433. Filed July 10, 1895.
Consists in the use of two partial signaling circuits in addition to the telephone speaking circuit.

AUTOMATIC TELEPHONE SYSTEM. Moise Freudenberg, Paris, France, 587,435. Filed Oct. 22, 1896.
Details of construction.

TELEPHONE CENTRAL STATION SIGNALING CIRCUIT. Geo. K. Thompson, Malden, Mass., 587,467. Filed May 25, 1897.
Consists of supplementary glow lamp signals to facilitate the work of "monitors" in exchanges.

CENTRAL OFFICE SWITCHBOARD SYSTEM. Wm. S. Harrison and Edward M. Harrison, Chicago, Ill., 587,502. Filed March 30, 1895.
Details of construction.

TELEPHONE TRANSMITTER. Owen Moran, New York, N. Y., 587,593. Filed Dec. 22, 1896.
Of the granular carbon type. Details of construction.

TELEPHONE TRANSMITTER. Oscar A. Enholm, New York, N. Y., 587,654. Filed Nov. 17, 1896.
Comprises two electrodes, and a composition of an adhesive elastic substance intermixed with conducting material, interposed between them.

PERSONAL

MR. SAMUEL INSULL was in New York last week on business of the National Electric Light and Edison Associations.

MR. LUTHER STIERINGER has left New York for a vacation in the Adirondacks, where he will spend a few weeks.

U. S. SENATOR G. F. HOAR is one of a trolley party making a trip along the North Shore from Boston to Gloucester, the round trip through beautiful country being about seventy-five miles.

THE STOCK MARKET

BROADENING AND BETTERING.

The stock market last week gave many signs of the better feeling in financial circles. Nearly 2,500,000 shares were dealt in, of about 175 different securities, a number far beyond the weekly average for years past, and prices advanced materially all along the line. The course in stocks has, however, been paralleled in other lines. New York bank clearings increased 44 per cent. as compared with a year ago, and thus show a much greater activity in trade. General trade through the country also exhibited great gains. Fifty of the leading railroads show a gain of 4 per cent. in gross earnings for June and of 13 per cent. net. Exports have continued large and wheat is in a stronger position than for years past. To all these and other causes for encouragement the stock market has responded eagerly, with a pace that seems almost too lively for the middle of August.

Of Western Union, 74,245 shares were sold during the week, going from 86 up to 91. General Electric, on sales of 48,130 shares, rose from 35 to 37¼. American Bell Telephone, on sales of 860 shares, went from 228 up to 237½. Brooklyn Elevated, which is soon to adopt electricity, and which was selling at 25 cents a share, $100 par, last Saturday, cannot now be had below 10, an advance in one week of 3,900 per cent.

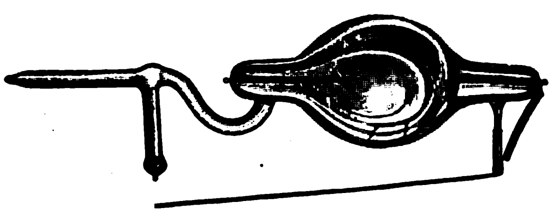
COPPER is quoted in Lake Superior ingot at 10¾; electrolytic bars, 10½. Large exports are being maintained, reaching 11,000 tons of fine copper last month.

STEEL RAILS are in good demand, heavy $19 and upward; light, from $24 to $28.50.

TRADE NOTES & NOVELTIES

SWETT & LEWIS VACUUM TUBE.

The Swett & Lewis Company, of Boston, have just got out a new adjustable vacuum tube; the form of which is the same as that put out by them before. In addition to this, however, is a chemical bulb and a pointer. The pointer works upon a hinge, and can be set so that when the vacuum in the tube gets to the proper height, a spark will pass from the pointer



SWETT & LEWIS VACUUM TUBE.

to the chemical bulb, and hold the vacuum at that point. By this means the tube may be run for hours without any perceptive change in the vacuum. The tube is very simple and easy to operate, and not liable to injury. Large numbers are being sold, and they are hearing very favorable comments from them. To quote from a letter received recently: "I have used the tubes continually, and think them the ideal tube."

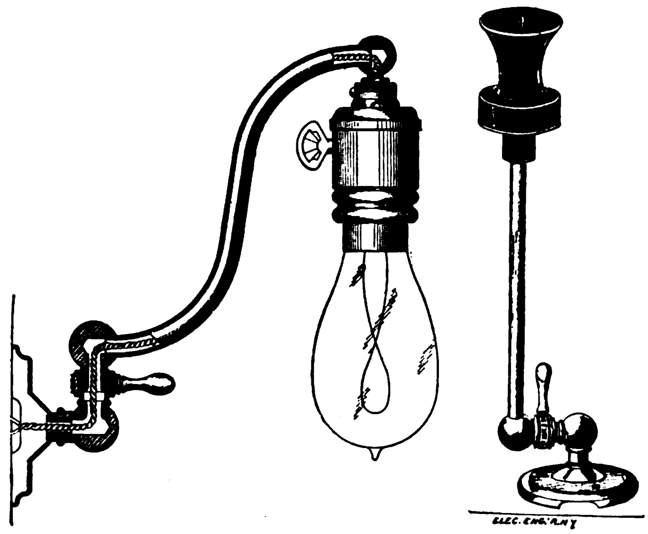
FULLER & CURTIS CO.

The Fuller & Curtis Company has just been incorporated, and will begin the manufacture at Detroit, Mich., of dynamos and other electrical apparatus, and heaters and ventilating appliances. The works are at the intersection of Russell street and the Grand Trunk Railway. The incorporators are Frank E. Kirby, Neil McMillan, C. D. Waterman, Rudolphus Fuller and W. H. Curtis. Mr. Fuller has been for seven years superintendent of the Fontaine Crossing and Electrical Company, and for thirteen years Mr. Curtis has been superintendent of the American Blower Company.

THE PETEREIT ADJUSTABLE SWING FOR ELECTRIC LIGHT OR TELEPHONE BRACKET.

WHEN swinging brackets of ordinary construction are placed on partitions, desks or other places which are not rigid but susceptible to vibration, the bracket is liable to be moved accidentally, and some means must be provided for quickly locking and unlocking it.

To provide a ready means of adjustment, such that the bracket can be movable or stationary, Mr. Albert Petereit, of



FIGS. 1 AND 2.—PETEREIT ADJUSTABLE BRACKET.

the Petereit-Wehrle Manufacturing Company, 140 Sullivan street, New York, has recently patented the device illustrated in the accompanying engravings.

As will be seen, the nozzle at the side of the lower ball, receives a nipple by which it is attached to the wall or desk bracket, while the swing is fitted into the upper ball. Between them is the lock nut, the actuating device of the invention. When the lock nut is quite loose, the joint will revolve freely, but cannot be accidentally displaced. When it is desired to have it remain in any position in which it is left, the lock is slightly tightened by being screwed down on the

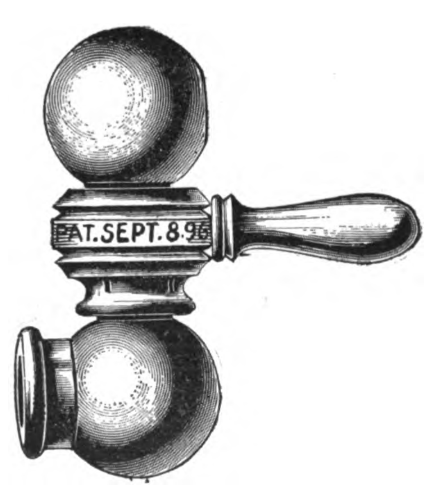


FIG. 3.—PETEREIT ADJUSTABLE BRACKET.

threaded nipple on which it works. This prevents the removal of the swing. When the lock nut is tightened still more the joint ceases to rotate, and will stay in any position in which it is left. When a proper adjustment has been made —that is, when the joint swings with just sufficient friction, the handle of the lock nut may be unscrewed and removed and then the lock nut cannot be moved except by tools, or by replacing the handle. The wiring can be very simply effected, as will be noted in Fig. 1.

Fig. 2 shows the device attached to a telephone transmitter.

WARD LEONARD ELECTRIC CO.'S CATALOGUE.

It is little more than five years since the enamel rheostat was called into existence, and yet the strides which have been made in the application of this exceedingly useful device have been enormous. We are forcibly reminded of the latter fact by a glance through the ninth catalogue just issued by the Ward Leonard Electric Company, of Hoboken, N. J., manufacturers of the Carpenter and Ward Leonard types of enamel rheostats.

The catalogue is replete with illustrations of a large variety of rheostats, reaching into the hundreds, standardized for use as field regulators, motor starters, theater dimmers, ventilating fan regulators, etc. A special feature of the catalogue is the description of the universal automatic motor starting rheostats, the automatic circuit breaker, which releases with "overload" and "no voltage"; the reversing controllers and other similar devices to which the Leonard Company have devoted special attention.

On glancing through the catalogue we note that a very marked reduction has been made in the price of the company's goods, a reduction averaging 25 per cent., and much more than this in the case of motor rheostats.

The Ward-Leonard Electric Company believe that they are one of the few electrical manufacturing concerns whose business has steadily increased during the last five years, and they attribute a great deal of their success to the comprehensiveness of their catalogues, from which electrical people both here and abroad have been able to order any desired rheostat with complete accuracy by a single code word or catalogue number.

The Leonard Company is represented in England by Veritys, Limited, London, and in Germany by S. Bergmann & Co., Berlin.

ADVERTISERS' HINTS

THE JEWELL BELTING COMPANY, Hartford, Conn., are advertising belt cement, belt dressing and pulley covering.

THE IDEAL ELECTRIC CORPORATION, Thirteenth and Hudson streets, New York, invite requests for estimates and prices on switchboards, panel boards and all copper switches.

OSTERBERG & SUTTON, Bowling Green Building, New York, consulting engineers and electrical experts, are making a specialty of gas and oil engine plants.

THE ORIENT ELECTRICAL COMPANY, Youngstown, O., still quote 17 cents on 10 and 16 c. p. lamps in barrel lots.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., say the Packard transformers are the nearest to perfection ever produced.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., continue to publish results obtained by the adoption of their system of heating by exhaust steam.

THE GENERAL ELECTRIC COMPANY advertise the Wirt short-gap lightning arresters for alternating circuits of any potential. They are in use on the Niagara-Buffalo transmission line.

NEW YORK NOTES.

THE HARMONIE CLUB, in West Forty-second street, is one of the prominent German clubs in the city, is undergoing considerable changes, one of the principal features being a ladies' club, which is being built as an annex to the present club house. Messrs. Herts, Tallant and Newton are the architects, and they have retained the firm of Osterberg & Sutton as consulting electrical engineers. This latter firm has also prepared plans and specification for a complete system of heating and ventilation, which having been approved of by the architects, will be adopted throughout the building. Quite a number of important features will be introduced in this new building, especially as far as electricity is concerned. A new electric elevator and a number of direct connected electric ventilators will be installed. The stage lights are being specially designed for artistic effects and the call system in the smoking and lounging rooms will have some special arrangements for the convenience of the members, which the engineers will not at present speak about. Work is to be commenced almost immediately.

WESTERN NOTES

WESTERN ELECTRIC COMPANY, Chicago, report that their "Economy" battery is meeting with considerable favor. This battery, which is of a high grade carbon type, has very good qualities and is sold at a low price. These combined advantages have been the means of creating quite a demand for it, which is still on the increase. The Western Electric Company have just completed a catalogue of the parts of single carbon high tension arc lamps, which gives illustrations, particulars and prices of even the most minute article used in these lamps, and users of arc lamps will find it to their advantage to have one of these catalogues at hand. The handsome picture of Niagara Falls, which is mounted on cardboard and termed "A Great Source of Supply," recently issued gratis by this company, presents a very attractive addition to the walls of an office or sitting-room.

Vol. XXIV. AUGUST 19, 1897. No. 485.

ELECTRIC TRANSPORTATION

THE NEW CONDUIT RAILWAY WORK IN NEW YORK.

AFTER several months of delay, caused by legal complications, the Metropolitan Street Railway Company, of New York, is now actively engaged in converting the present horse roads on Eighth and Madison avenues into electric conduit roads.

In planning the new work the engineers of the company have been guided largely by the experience gained in the operation of the Lenox avenue conduit road which is now in its second year.

Our engraving, Fig. 1, shows a section of the conduit. As will be noted, the entire depth of the yoke is only 2 feet 6¾ inches, so that but a very shallow excavation will be required, in marked contrast to the usual depth of a cable conduit. The yokes will be spaced 5 feet on centers, and the hand holes where the insulators are attached, at distances of 15 feet.

The conducting rail is a modified T-section, with the edges lapped over, so as to give additional stiffness to resist the pressure of the plow contacts.

The conducting rails are held in position by fork brackets, which are held firmly by porcelain insulators. Fig. 2 shows one of these insulators in part section. These differ somewhat in construction from those used on the Lenox avenue line. They are supported at two points and bolted to the slot rail and conductor rail. The insulator is enclosed in an outer inverted bell of cast iron; within this is cemented the glazed porcelain insulator, and inside of this is cemented the steel screw pin that supports the fork to which the conductor rail is attached. The insulator is 7¼ inches high over all and the conductor rail is 14 inches below the top of the slot rail.

The construction adopted at manholes and cleaning pits is shown in the illustration, Fig. 3. The manholes are 5 feet deep below the surface, with catchbasins connected to the sewer. These are placed 150 feet apart on levels, but at more frequent intervals on grades. The pits are also employed for connecting the feeders to the conductor bars. It will be noted that the yokes of the conduit have a stiffening web cast on at the bottom, which is embedded in concrete; this enables a shallower construction of conduit to be employed.

In order to provide current for the new lines the company is installing two new electric power plants. One of these is situated in the present cable power house on East Twenty-

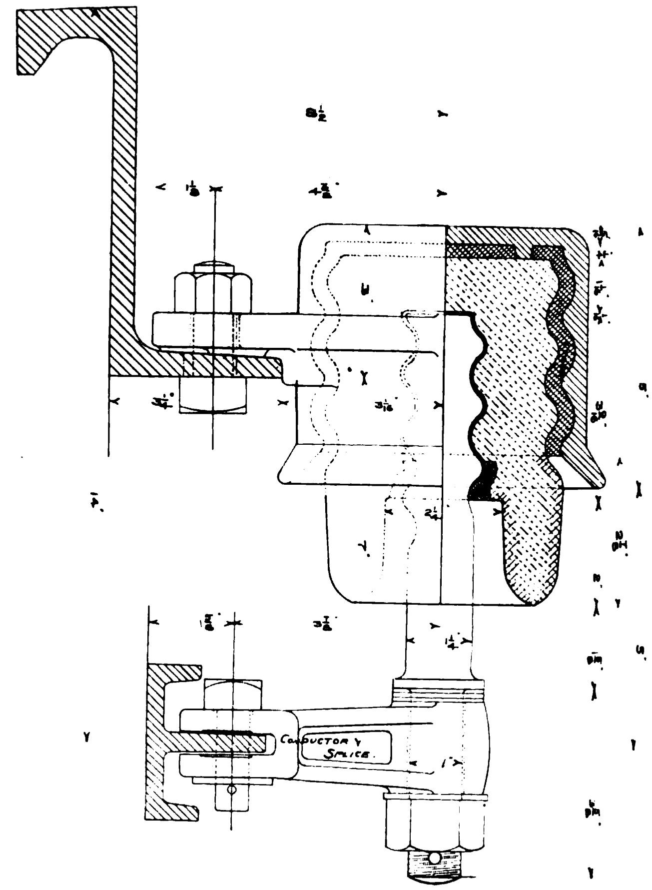

FIG. 2.—INSULATOR FOR NEW CONDUIT ROADS IN NEW YORK.

fifth street, and is shown in plan in Fig. 4. Placed alongside the present cable drives there will be ranged four 800 k. w. G. E. generators, driven by cross-compound engines, built by

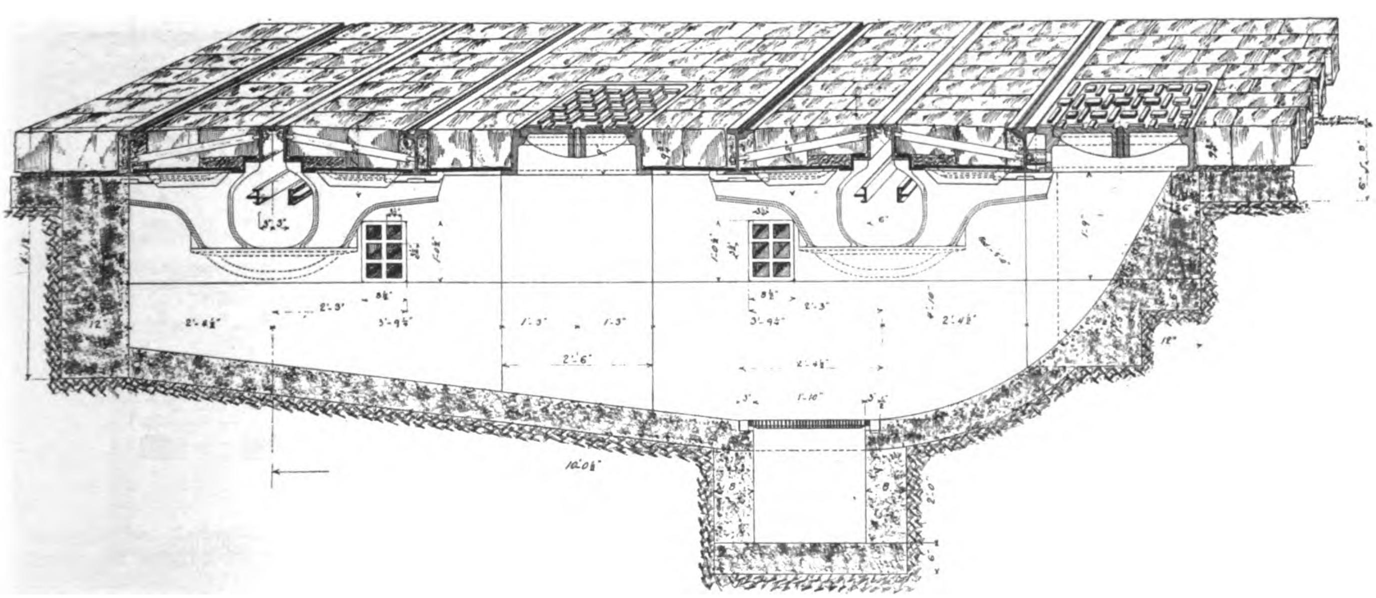

FIG. 3.—MAN HOLE AND CLEANING PITS, NEW CONDUIT ROAD CONSTRUCTION, NEW YORK.

The rails will be 9 inches high, weighing 106 pounds to the yard, with a 7-inch slot rail, the latter similar to that employed on the company's present cable system.

the Pennsylvania Iron Works Company, of Philadelphia. To provide steam for these new engines 8 additional Babcock & Wilcox boilers will be installed, of 250 h. p. each, Fig. 5.

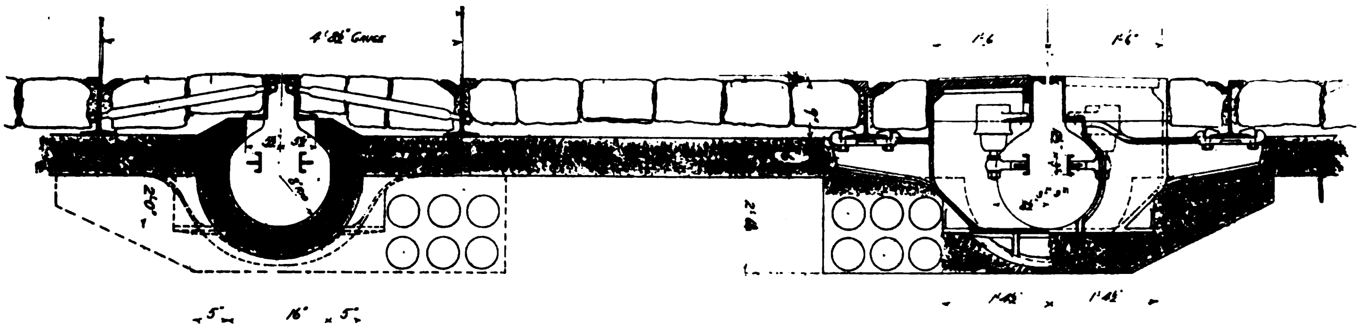

Fig. 1.—Section of New Electric Conduit Roads, New York.

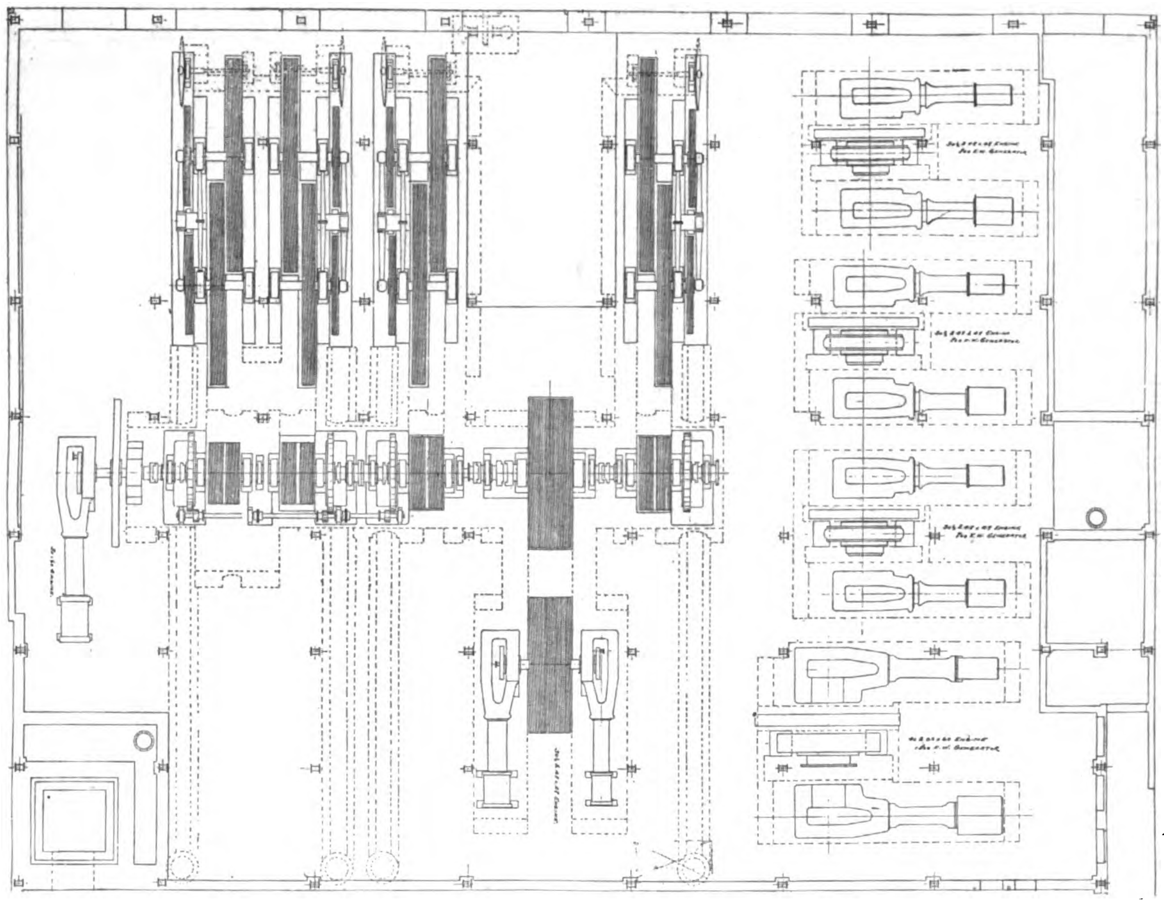

Fig. 4.—Arrangement of Generators in 25th Street Railway Power House, New York.

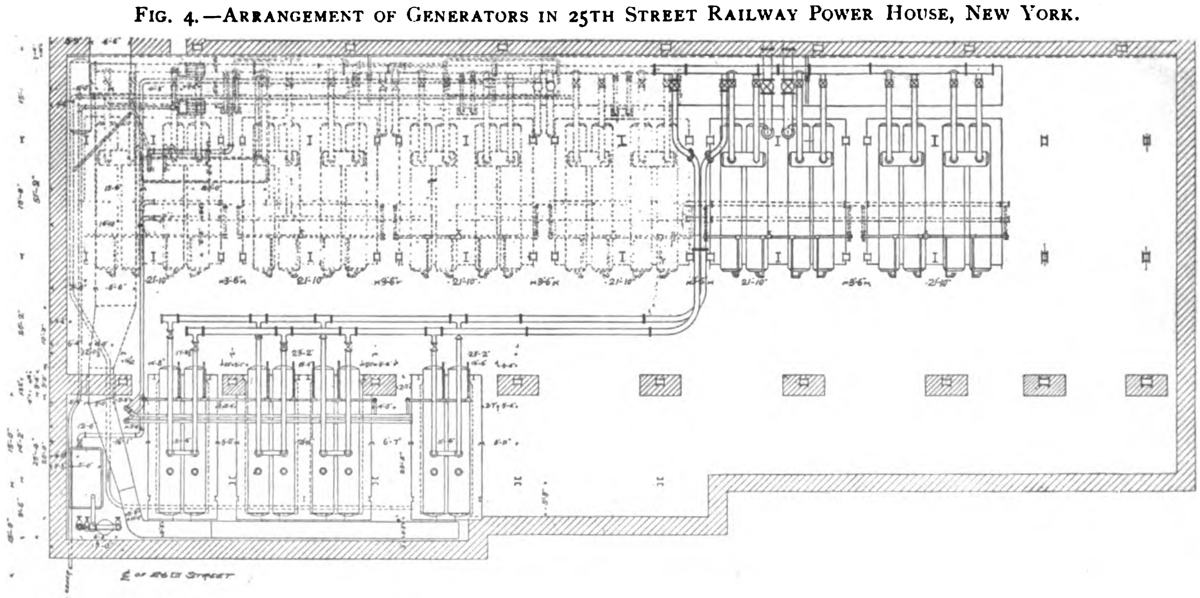

Fig. 5.—Boiler Arrangement in 25th Street Railway Power House, New York.

Owing to the lack of space, one-half of the new boilers will be placed under the sidewalk, as shown in the sectional view, Fig. 6, and these will be provided with the Box automatic stokers.

This station will supply current to all lines below Fifty-

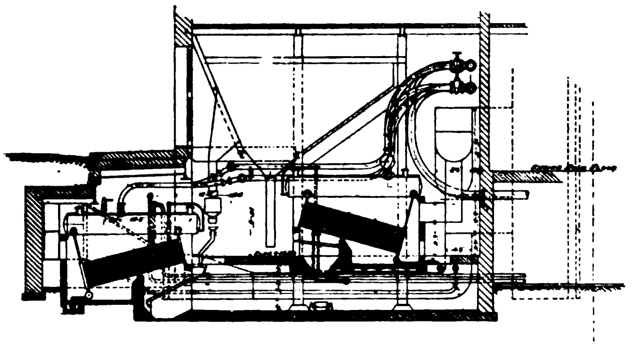

Fig. 6.—Section of Boiler House.

ninth street. Above this point current will be furnished from the 146th street station, which now supplies the Lenox avenue line. This station is now being extended to make room for the new power equipment.

ELECTRICITY AS A MOTIVE POWER ON ELEVATED RAILWAYS.—III.

BY PROF. S. H. SHORT.

TRAIN No. 2.

Character of Service; Elevated Railway:

Number of cars in train	2

ation; the current necessary to operate the trains at full speed, and the average current and horse-power for the various trains.

MISCELLANEOUS

ROTARY TRANSFORMERS.—II.

BY C. F. SCOTT.

ALTERNATING Current in a Rotary.—An alternating current varies from zero to a maximum, having a particular value for each successive position in a revolution of the armature. In an armature revolving in a two-pole field the current strengths for a number of positions of the armature are shown in the accompanying diagram, Fig. 5. The strength of current in the wires on the surface of the armature is indicated by the thickness of the circles representing the armature. The shaded portion indicates that the current is flowing in one direction and the light portion that the current is flowing in the opposite direction. The terminals are represented by black dots within the inner circle. The armature is assumed to be between two field poles, one directly above and the other directly below it, similar to those in Fig. 1.

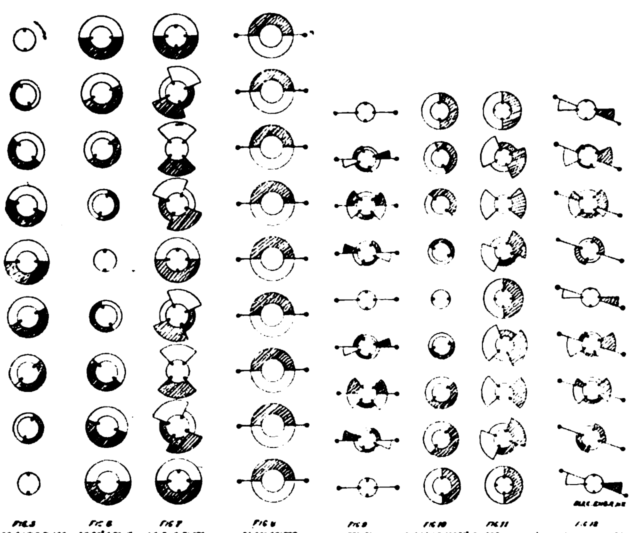
The upper circle in the figure represents the armature in the position of zero e. m. f. and of zero current also, when the e. m. f. and current are of the same phase. The second circle shows the condition when the armature is moved through one-quarter of a right angle, or 22½ degs. The e. m. f. and current are not 38 degs. of the maximum which will be reached, and they are in one direction of the shaded section of the diagram, and in the opposite direction in the other half.

The next circle shows the 45 deg. position, in which the strength of the current is 71 degs., and the fourth circle shows the condition when the next arc has been passed and the value is 92 degs. of its maximum. The fifth circle shows

the 90 deg. position, in which e. m. f. and current have reached their maximum values. This circle represents the same condition that was shown in Fig. 1; the half of the armature nearest one pole is carrying current in one direction, while that nearest the other pole is carrying current in the opposite direction. A vertical line passing through the center of the poles and the armature is seen to have an equal quantity of positive and of negative armature current on each side; as the result the armature currents do not have any effect in increasing or diminishing the magnetization of the fields. The conditions for the next quarter of a revolution are given in the lower circles, and the conditions in subsequent positions are simply a recurrence of the cycle, which is shown in the nine circles given.

In a two-phase machine the two e. m. f.'s are exactly similar, except that one occurs 90 degs., or a quarter of a revolution later than the other. The connections to the armature winding are exactly similar, except that one is made at a point 90 degs. from the other. The e. m. f. and current in the second circuit are, therefore, identical with those which were in the first circuit a quarter of a revolution before. Diagrams for the second circuit are given in Fig. 6. A comparison of Fig. 5 and Fig. 6 shows that the current in one is maximum when that in the other is zero.

If both circuits be derived from the same winding then the two currents tend to flow in the same wires, and the actual current flowing is the resultant of the two. It will be the sum when the two currents are flowing in the same direction and the difference when they are flowing in the opposite direction. Combining Figs. 5 and 6 in this way Fig. 7 is derived. The upper circle is seen to correspond exactly with that of Fig. 6, as there is no current in Fig. 5 at this time. The condition obtained at each quarter revolution is the same, and is shown by the first, fifth and ninth circles. The current in the intermediate positions is seen to be different in different sections of the armature winding. In the 45 deg. position there are two quarters of the armature which have no current. It will be observed that the area in Fig. 7 is considerably less than the sum of the areas in the two figures representing the component currents. If the current in the armature wires of Fig. 5 and of Fig. 6 is represented by 1 in each case, then the current in the armature when both circuits supply their currents from one winding, as on Fig. 7, will not be equal to the sum of two, or 2, but will be equal to 1.4.



FIGS. 5 TO 12.

A vertical line drawn through the nine circles in each of the three figures shows an equal area of shaded section and an equal area of light section on each side, so that there is no resultant effect on the magnetization of the fields.

Direct Current in a Rotary.—The current in an armature of a direct current machine, in which the brushes are set in a neutral position, having no lead, is shown in Fig. 8. It will be noted that the current in all parts of the armature is of the same strength, and that the current occupies the same position with respect to the field poles regardless of the angular position of any particular armature conductor.

An armature which carries both the alternating current and the direct current in the same winding will have a resultant current, which is the sum of the two in those conductors in which the currents tend to flow in opposite directions. The successive circles in Fig. 7 (which represent the current in a two-phase alternating current motor), and in Fig. 8 (which represent the current in a direct current dynamo), are combined to give the corresponding circles in Fig. 9, which, therefore, represent the actual current in the armature conductors of a rotary transformer in successive positions. It will be observed that in the first position there is no current in the armature. In this position one of the alternating current circuits is delivering no current and the other is delivering its maximum current. The latter circuit is at this moment connected to those commutator bars on which the direct current brushes are making contact, so that the current passes directly from the alternating current circuit to the direct current circuit, without transversing the armature winding. The same condition prevails when the armature has moved through 90 degs., and the commutator bars to which the second circuit is connected have come under the direct current brushes and the current in this alternating circuit has reached its maximum value. The continuous strength of the direct current is just equal to the maximum value of the alternating current. In intermediate positions of the armature the current varies through a considerable range, as is indicated by the intermediate circles.

The figures clearly indicate that the current in the armature conductors is less when the machine is used as a rotary transformer than it is when used as a direct current generator. An inspection of the circles in the figure representing the rotary shows that the current in the armature conductors which are directly in front of the field poles—that is, on the upper and lower portions of the circles, is very much less than it is in the figure representing the direct current generator. As a consequence the distortion of the field magnetism is very much reduced and the conditions for commutation are, therefore, greatly improved. The iron losses arising from field distortion are very small in the rotary, as there is so little distortion.

The Induction Rotary.—It has been stated that if the field current of a synchronous machine be reduced there will be an increased armature current, which can compensate for the decreased field current and maintain a constant magnetization. In a suitably designed machine the field current may be reduced to zero, and the whole magnetization derived from the armature current. The current in this case, as has been shown in Fig. 2, has its maximum value in quadrature, or 90 degs. from the maximum e. m. f. A single-phase armature, in which the current is in phase with the e. m. f., is represented in Fig. 5. If the current lag 90 degs., then the relation of currents may be seen in Fig. 10, in which the current has its maximum value in a position 90 degs. later than that at which the maximum value occurs in Fig. 5. It will readily be seen that in Fig. 10 the current represented by the shaded portion of the diagram is almost entirely on one side of the vertical line, so that the currents in the armature are in proper position for magnetizing the field. The current in the armature of a two-phase motor which is magnetized by the armature currents is shown in Fig. 11. It will be noted that the current is distributed in the same way as in Fig. 7, which represents a two-phase motor in which the currents are in phase with the e. m. f.'s, except that the corresponding currents occur when the armature is moved through 90 degs. The position of the current in the armature is such that the shaded portion lies almost entirely on one side of the vertical line passing through the center of the shaft and the field poles, and consequently is in the most favorable position for magnetizing the fields. If such an induction motor be provided with a commutator, direct current may be delivered and the action of the machine will be essentially the same as if it were excited by current in a field winding instead of current in the armature winding.

The magnetizing effect must be practically constant at all times. The current in phase with the e. m. f., which therefore supplies energy, which is in turn delivered to the direct current circuit, varies with the load. The resultant current therefore varies with the load. It will be found that the alternating current to the motor, as well as the currents in the armature windings, is not equal to the arithmetical sum of the magnetizing current, which can be measured at no load, and the current which is useful in supplying the direct current circuit. The resultant current is less than the sum, and the difference becomes greater and greater as the motor is loaded.

Effect of Change of Lead.—An interesting and important variation is produced when the angular position or lead of the direct current brushes is changed. Omitting for the present the lagging or magnetizing current and considering only the current which is in phase with the e. m. f. and supplies energy for the direct current, the distribution of current with no lead is shown in Fig. 9, and with backward lead of 22½

degs. is shown in Fig. 12. The currents in these figures are similar except in the arcs through which the brushes have been moved from their neutral position. In Fig. 9 it was noted that there was no magnetizing effect produced in the field of the armature current. In Fig. 12 it will be observed that the currents in the sections in which the brushes have been moved are so located as to produce considerable magnetizing effect; as there is a current in one direction on one side of the armature and in the other direction on the other side of the armature. When the brushes have this position the current in the armature resulting from the currents which are in phase with their e. m. f.'s and which supply the direct current produce a magnetizing effect which will therefore reduce the amount of magnetizing current necessary from other sources. In an induction rotary in which the brushes are given a backward lead this effect can be secured, thus requiring a less amount of lagging current, or current which is 90 degs. behind its e. m. f., when the machine is loaded.

As stated above, if the brushes are given a backward lead the magnetizing current will decrease, while if they be given a forward lead it will increase. This effect is useful in regulating the voltage of the direct current delivered by the induction rotary.

The induction rotary possesses essentially the same characteristics as the rotary with excited field in the increase of output, which can be obtained from an armature of given size over that which can be obtained from a direct current machine.

The induction rotary possesses great superiority over the rotary with excited field in its facility for adapting itself to the conditions of the circuit. A synchronous machine, as has been pointed out, must be adapted to the circuit which supplies it in wave form and in e. m. f. An induction machine has no characteristic wave form nor e. m. f. In these respects it is not active but passive. It receives its magnetizing current from the alternating circuit in the same way that an ordinary transformer or converter does. In these regards the induction rotary possesses the same marked advantages over the rotary with excited fields as the induction motor possesses over the synchronous motor with excited field.

The induction rotary has sufficient starting torque to be self-starting. The rotary with excited field is in general capable of self-starting, but under conditions which are not as favorable to the circuit as the induction rotary, as the latter requires much less starting current.

When the conditions of speed or e. m. f. on a circuit are fluctuating, the induction rotary is much less liable to be affected than the rotary with excited field. In fact, in a certain test a rotary transformer of the direct current field type was so sensitive to variations in the circuit that it could not be operated from a commercial circuit, but was able to run with perfect steadiness as an induction rotary when its field circuit was open. The machine was not properly proportioned for running continuously as an induction rotary, as the exciting current was excessive. This, however, could be modified by making slight changes in the design on the machine, adapting it for operation as an induction rotary. I have seen two induction rotaries running in multiple which divided the load in any ratio that was desired, depending on the relative lead of the brushes. The induction rotary is best suited to circuits of a low number of alternations, and, except in small sizes, is not well adapted for 7,200 alternations or 60-cycle circuits.

Regulation of Voltage.—The e. m. f. at the commutator of a rotary is related to that of the alternating current at the collector rings by a definite and practically constant ratio. A commutator e. m. f. of 100 volts requires an alternating e. m. f. of 70 to 80 volts, depending upon the wave form. A variation of the direct current voltage, therefore, requires a corresponding variation in the alternating current voltage supplied. This may be varied either by changes in the generator or in the transmission apparatus between generator and rotary, or it may be made by changes in the rotary itself, either increasing the field strength or otherwise.

(1) The voltage may be varied by varying the e. m. f. upon the generator, consequently increasing the e. m. f. throughout the system. This is in general applicable only when a generator supplies one rotary alone.

(2) The voltage may be varied by changes in the ratio of the windings of transformers which are placed between the generator and the rotary. This regulation may be done in one of several ways. (a) Loops may be brought out from the transformer for supplying voltages differing by steps of, say, 10 per cent. and the rotary before being started may be connected so that it receives one of these voltages, there being no provision for changing the voltage while the rotary is running. (b) The lowering transformer which supplies current to the rotary may be made with an adjustable or moving secondary, by which the relation between the primary and secondary coils is varied, effecting gradual changes in the e. m. f. delivered to the rotary. (c) The transformers may be provided with many loops connected to a switching device or controller, by which the e. m. f. of each phase can be raised or lowered by, say, 1 per cent. steps. In such a regulator the circuits may be arranged so that one circuit is switched at a time, the rotary being operated as single phase during the instant of switching over.

(3) An auxiliary machine may be placed on the shaft of the rotary or driven by a separate motor. This machine may be excited by the direct current from the rotary. Such an auxiliary generator or booster will have an e. m. f. dependent upon its field strength and may therefore be used for increasing the e. m. f. as the load increases. It may be wound for alternating current and increase the e. m. f. of the alternating circuit before it reaches the rotary, or it may be wound as a direct current machine and add to the e. m. f. delivered by the commutator of the rotary.

(4) The field strength of the rotary may be increased as the load increases by compounding it in the same way that an ordinary direct current machine is compounded. A low-field charge at light load will cause a lagging current to flow, which will cause a drop in e. m. f. if there be self-induction in the circuit. If the field current be increased the lagging current will become less and the drop will become less. A strong field will increase the e. m. f. at the alternating current end of the rotary, above that which the circuit would otherwise deliver. This e. m. f. may be kept the same at full load as it is at no-load, or may be made to increase so that the alternating e. m. f. at the rotary is greater at full load than at no load. In this method of operating the current to the motor is usually a lagging or a leading current and involves a power factor less than unity.

(5) In the induction rotary in which there is no direct current field charge the brushes may be given a backward lead so that the direct current flowing in the armature replaces in magnetizing effect a portion of the lagging alternating current which magnetizes the machine at no load, and therefore reduces the amount of lagging current supplied to the machine. This causes a less drop in generator and transmission circuits, so that there may be an increasing e. m. f. between no load and full load.

ELECTRIC FURNACES.—II.

BY LIEUT. F. J. PATTEN.

IT was discovered very early in the art that this problem, like all others in electricity, had two independent solutions, one on the lines of the arc to which alone reference

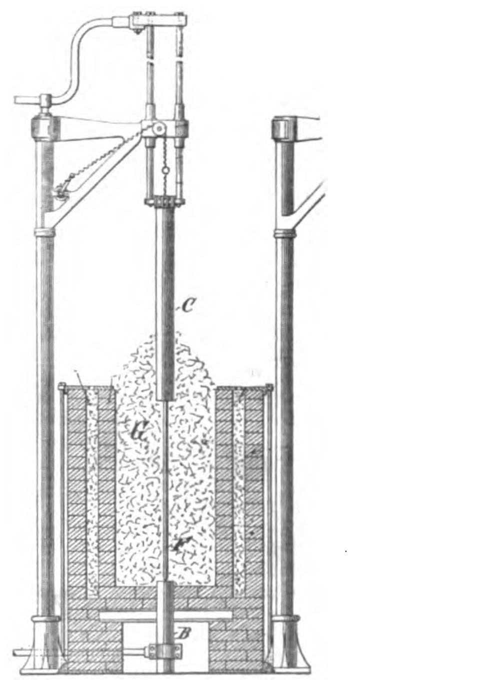


FIG. 7.

has thus far been made, and the other upon an incandescent system or method. In Dr. Borchers' recent work, "Die Elek-

trometallurgie," which is a complete epitome of the art from its beginning, he shows a number of electric furnaces built upon the incandescent plan, dating back into the eighties and early nineties; nevertheless, we find such a system patented in the United States as new in principle as late as 1896, but it may be well to add that Dr. Borchers' work had not appeared at the date of issue of the patent. Such a system is shown in Fig. 7, and is certainly as beautiful as it is simple in operation.

The two main electrodes, C and B, are united by a slender pencil of carbon, F, which is entirely embedded in the contents of the furnace, G, which it is intended to treat. When a sufficiently heavy current is turned on, this slender carbon

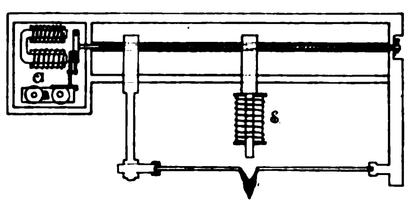

Fig. 8.

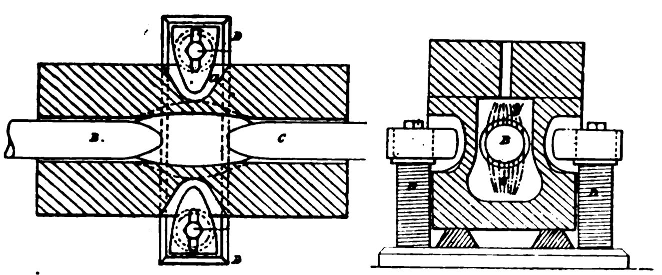
pencil is fused; but it seems that the temperature of fusing carbon is sufficiently high to determine the union of the carbon and calcium of the lime and coke mixture. Thus a slender pencil of calcium carbide is formed where the carbon pencil first was; this increases gradually in size until the resistance becoming too low the upper carbon is lifted gradually further away from the lower one, and in this manner the carbide nugget is both elongated and enlarged. The method is ingenious and does away entirely with the arc and its terribly roaring noise. The indications are that the incandescent method is more economical of power than the arc; there is certainly every reason that it should be so, and if tests upon a large scale show this to be the fact the arc furnace for commercial work will be a thing of the past. Further reference will be made to this system later, indicating a way to greatly increase the output of a single operation on the incandescent plan.

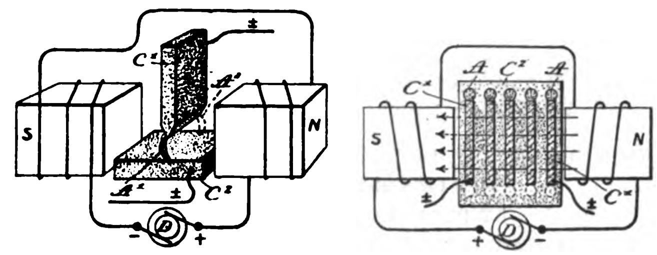
Early in the state of the art the idea of deflecting and fixing the position of the working arc by placing it in a magnetic field was availed of; Dr. Borchers, I believe, gives credit for first doing this to Dr. Zerener, of Berlin. His apparatus is shown in Fig. 8, and the patent bears date of 1889. The arc is sprung at D, between the two carbon electrodes, and imme-



Figs, 9 and 10.

diately over the arcing space a powerful electromagnet, E, is suspended. Its magnetism, according to well known principles, causes the arc to take the position shown, in which it will be held as long as the magnetic field is unchanged in direction. I find, however, a German patent showing the same thing applied to a furnace, and which antedates even Zerener's description by two years. It is a German patent granted to three Englishmen—Rogerson, Statter and Stevenson—in 1877, the two principal drawings of which are here reproduced in Figs. 9 and 10. Fig. 10 is a plan view looking down upon the furnace and Fig. 10 is an end elevation. B and C are the carbon electrodes projecting into the furnace, between which the arc is established; D, D, is a powerful electromagnet, the poles of which are brought as close to the arc as possible. The arc is, therefore, established in a strong magnetic field and is deflected vertically upward or downward according to the polarity of the magnet, the latter serving to diffuse the arc and prevent it from merely working at a central point between electrodes. In all these cases the arc is fixed in position, being diffused somewhat and deflected to a certain position, where it is permanently held.

In view of the fact that the idea of using a magnetic field for determining and fixing the arc in position is so old, it is more than strange that the same agency should not have been applied to move the arc from place to place, or to give it a reciprocating "or rotary motion." It is believed that this was first accomplished by the writer and the principle gives rise to an entirely new system of electric furnace operation involving the use of reciprocating or sliding arcs, rotating arcs, and in the incandescent line a rotating or revolving current incan-



Figs. 11 and 12.

descent system of furnace operation through use of which the power expended is made to do a maximum of work. The reciprocating or sliding arc furnace system is illustrated in Figs. 11, 12 and 13, the former indicating the principle of operation and the latter being the section of a furnace of this description.

In Fig. 11, C' represents an upright slab of carbon placed at arcing distance from the horizontal carbon slab, C², and N S are the poles of an electromagnet, so placed that the arc between the electrodes is normally in the field of the magnet

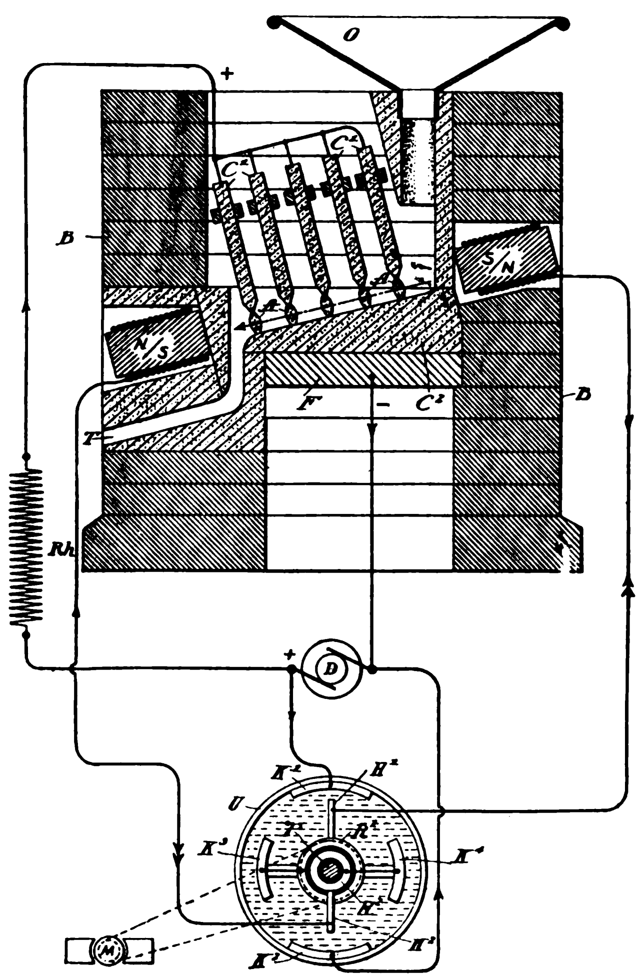


Fig. 13.

of which the lines of force flow from N to S, then the arc between carbons will assume a position dependent upon the direction of current flow and the lines of force. Thus, if the lines of force have the direction N to S and the current flows from the upper to the lower carbon, then the arc will assume the position A' at the left-hand corner of the upright carbon slab. Now, if either the current should change direction or the magnetic field should reverse, then in either case the arc would pass over to the right-hand edge or corner of the

upper carbon slab, assuming the position A'. In these physical conditions, therefore, lies the possibility of moving the arc to and fro across the edge of the upper carbon slab.

Fig. 12 shows an arrangement of a number of upright parallel electrodes placed in juxtaposition to a carbon slab forming the other electrode. The several arcs in such case between upper and lower electrodes traverse back and forth from side to side of the upper carbon with each alternation of current, and material passed between the upper and lower carbons on the lower carbon slab is attacked by the electric arcs,, A A, in rapid succession as they vibrate to and fro over the passing material.

DESIGN, CONSTRUCTION, AND TEST OF A 1,250 WATT TRANSFORMER.[1]

BY PROF. HENRY S. CARHART

TWO of my students, Mr. Trevidick and Mr. Harrison, undertook, under my supervision, the design and construction of a transformer to determine how nearly theory dictates correct practice. They chose the core type instead of the shell chiefly for construction reasons, as the iron for the core type can be cut at the tinsmith's without a die. At the same time this type departs so widely from the common design that they were thrown more on their own resources.

In the core type the number of turns of wire is greater than in the shell type, if the copper and iron losses are to be nearly equal to each other. This is the condition for highest efficiency.

For high efficiency under a light load, the number of turns of copper must be increased. But this causes a larger drop in potential and so impairs the regulation.

Design.—Preliminary trials showed that the number of primary turns should not be less than 1,200 and the secondary

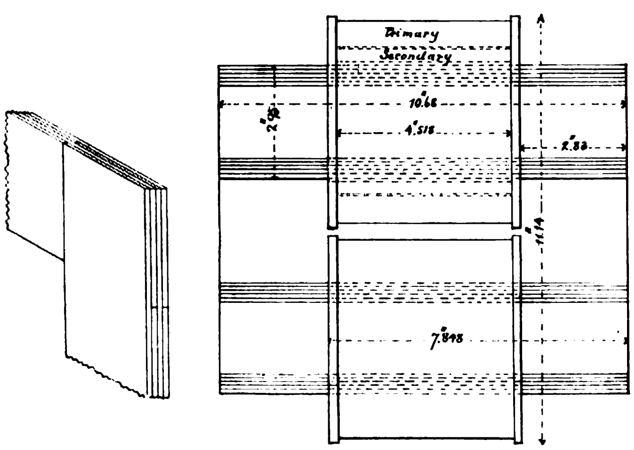

FIG. 1.

120 (or 60 in parallel). To determine the cross-section of the iron, it is easily shown that

$$A = \frac{E}{4.44\ nNB}, \text{ or, in this case, } A = \frac{1,010 \times 10^8}{4.44 \times 135 \times 1,200 \times 3,000}$$

= 46.8 sq. cm. = 7.25 sq. in.

Allowing 10 per cent. for oxide, the width of the core plate is 2.95 inches.

On the basis of 1,000 amperes per square inch, the primary was made of No. 17 d. c. c. wire and the secondary of No. 8. Winding the secondary in two layers of 30 turns each on each spool, the length of the core plates becomes 7.848 inches.

The estimated length of the secondary was 124.8 feet and its resistance at 40 degs. C., 0.0847 ohm. For the primary the length was 1,602.6 feet and its resistance 8.8 ohms.

The copper losses at full load are then 13.75 watts for the primary and 13.23 for the secondary. The hysteresis and eddy current losses were both combined under Steinmetz's formula with a hysteretic constant, 0.0025. The indicated iron loss was 39.11 watts in a volume of 193.27 cubic inches, and a flux density of 3,000 lines per sq. cm. Hence, the total estimated losses were 66.09 watts, and the efficiency 95 per cent.

The magnetizing current was computed by Thomson's formula as 0.048 ampere. The power component to supply the loss by hysteresis and eddy currents was 0.039. The total no load current is the resultant of these two in quadrature, or 0.061 ampere.

Construction.—Wheeling iron 15 mils thick was used for the core. It was carefully annealed out of contact with the air by heating in a furnace to 923 degs. C., and then slowly cooling. The above temperature is higher than the critical one at which iron ceases to be magnetic.

After winding and drying, the transformer was assembled by interlarding the end plates between those of the cores and compressing between ribbed clamps with the bolts through projecting ears.

Test.—The resistance of the primary at 40 degs. C. was found to be 8.46 ohms; that of the secondary, 0.083 ohm. The weight of the primary was about 9.25 pounds and of the secondary, 6 pounds. The iron loss, measured in the usual way by a Weston wattmeter, was found to be 34.5 watts.

The regulation was determined by a method of comparison by means of two voltmeters, and the voltage from no load to full load varied only 2.3 per cent. The cross-flux or magnetic leakage on full load was 2.65 per cent. The details of this measurement were given.

The following efficiencies were found by test: Load of 371 watts, 90.93 per cent.; 742 watts, 94.42; 1,020 watts, 95.12; 1,286 watts, 95.37; 1,475 watts, 95.43.

The comparison between observed and computed values is interesting.

	Observed.	Computed.
Resistance of primary at 40 degs. C.. ohms	8.46	8.80
Resistance of second'y at 40 degs. C....ohms	0.083	0.0847
Copper loss, primary, full load.......watts	14.07	13.75
Copper loss, secondary, full load.....watts	13.07	13.23
Iron losses ....watts	34.5	39.11
No load current ....amp.	0.05	0.061
Efficiency at full load............per cent.	95.4	95.

EXHIBITION OF INSTRUMENTS FOR DETERMINING THE FREQUENCY OF AN ALTERNATING CURRENT.[1]

BY GEORGE S. MOLER and FREDERICK BEDELL.

The instruments here included are two in number. The first one, which has already been described,[2] consists of a small synchronous motor brought to speed by a crank handle connected with the motor by a suitable train of gears. The apparatus contains an electrically operated counter, so arranged that its reading gives the exact value of the frequency of the alternating current with which the synchronous motor is supplied. The whole apparatus does not weigh over nine pounds. The reading is correct to within .05 of an alternation.

The second instrument consists of a sonometer or monochord. The alternating current flows through a piano wire mounted upon a sounding board. The wire passes between the poles of a permanent magnet. By means of a sliding bridge the period of the wire may be made equal to that of the alternating current. This is indicated by the vibration of the wire. A scale is arranged so that the position of the bridge indicates the frequency directly.

SHOULD LIGHTNING RODS BE INSULATED FROM THE BUILDING?

BY N. MONROE HOPKINS.

WHY do lightning rod men continue to erect insulated lightning rods when authorities on the subject agree that the uninsulated type is the correct one? The lightning rod men exercise the greatest care in keeping the rod from touching any portion of a building, and the electricians and writers of text-books who have studied the question prescribe that the rod should be in intimate contact with all the masses of metal about a building, such as the plumbing and metallic roof. In the case of the insulated rod protection is sought, by parrying the blow, so to speak, carrying the electricity to earth, while the theory of the connected type depends on a silent streaming of electricity between the cloud and building, equalizing quietly the tremendous difference of potential.

As is well known, in dealing with static electricity, a charged body will induce a charge of opposite sign in a body brought in proximity, and if the bodies are moved together, within "striking distance" a discharge, or spark, or series of sparks, will take place, neutralizing the two charges. Let us take the case of a positively charged cloud hanging over a building. The building will immediately become electrified negatively, the electricity being densest on or near the roof, the highest point. If this roof is metallic and directly connected to a network of rods carrying many sharpened points it will be seen by any one who has had anything to do with

[1]Read before the A. A. A. S., at Detroit. Abstract.

[1]Abstract of paper presented at the Detroit meeting of the A. A. A. S.
[2]See "A Synchronous Motor for determining the Frequency of an Alternating Current," by George S. Moler, Physical Review, March-April, 1897.

static electricity, that each point will "stream" or glow with a brush discharge until the tremendous difference of potential is neutralized and rendered harmless.

Of course, if the number of sharpened points are few, and the charge is a large one, the silent equalizing flow which drains the building, so to speak, of the dangerous accumulation, will be overtaxed and a flash will take place, with more or less mechanical disturbance.

It is the opinion of the writer that a building provided with stout rods, connected with all iron work, especially about the roof, having a great number of sharp projections, will be very secure from an actual lightning stroke, and should a flash ever take place between cloud and building, the mechanical disturbances will be far less in the case of the connected rod.

AGEING AND REFINING ALCOHOL ELECTRICALLY.

Mr. O. W. Swift, of New Haven, Conn., has designed an apparatus for electrically ageing alcohol—that is, eliminating the fusel or volatile oils, which constitute the most dangerous elements in alcohol liquors. Tests made by United States internal revenue officials demonstrate that liquors subjected to the Swift process undergo a very perceptible change, and take on the milder form of liquors mellowed by age.

LETTERS TO THE EDITOR

IRON CONDUITS AND THE UNDERWRITERS.

THE Suburban Underwriters, New York, have recently sent out a circular letter, accompanied by a copy of the latest rules and requirements of the National Board of Underwriters, and quotations from those rules are submitted below, as being probably as salient as any suggestions or rules among them:

RULES OF 1897.

General Suggestions.

"In all electric work conductors, however well insulated, should always be treated as bare, to the end that under no conditions, existing or likely to exist, can a grounding or short circuit occur, and so that all leakage from conductor to conductor, or between conductor and ground, may be reduced to the minimum."

Rule 14, Paragraph D.

"Bushings must be long enough, etc. The tube then is to have a non-conducting bushing pushed in at each end so as to keep the wire absolutely out of contact with the conducting pipe."

Rule 41, Paragraph J.

"Plain iron or steel pipes of equal thickness, etc., * * * may be used as conduits, provided their interior surfaces are smooth and free from burs * * * interior surfaces coated or enameled to prevent oxidization."

On the lines of discussion, as started by "Jim Crow" and "Doe Bird," relative to the use or non-use of plain iron conduits, I think that the National Board can hardly realize or appreciate just what their rules imply or permit, and this statement is made inasmuch as my acquaintance with the officials of the leading companies representing the National and other Boards in this locality convinces me that it is impossible that men who have made such a success of fire insurance, should now deliberately, and apparently with considerable exercise of care, issue rules and formulate suggestions, which, in and of themselves, are grossly inconsistent to even a novice in the methods of installing electric wires and appliances.

Your readers will note that under the "General Suggestions," given above, the underwriters desire that all conductors should always be treated as "bare"; and yet in their rules permission is granted for the use of "plain iron or steel pipe" for containing not only one conductor, but both conductors of a circuit! It may be asked, in all fairness, is this following out their own suggestion, and treating conductors as "bare"?

Again, in their rules, a portion of which has been quoted, wires in passing through brick walls "must be encased in an iron-armored conduit" and "no other method, etc., will be accepted"; and it is also noted in these latest rules, that tubes, where they pass through floors, if they are iron, must be supplied with a non-conducting bushing, "so as to keep the wire absolutely out of contact with the conducting pipe."

Now, in all seriousness (and it is indeed a serious subject, and one not to be lightly pushed aside), how can any body of men, professing to be experts, formulate a set of rules which are so contradictory as the rules of 1897, as is evidenced by the quotations which have been made from the copy sent, as well as from the letter of the Suburban Underwriters?

If it is considered a hazard to place a single conductor within a short piece of plain iron pipe where passing through a wall or floor, so that the insurance inspectors must insist upon the wire being protected from the "conducting pipe" by a non-conducting bushing, must it not of necessity be logically far more hazardous to place two conductors of a circuit within one "plain iron or steel pipe," and permit this throughout an entire installation?

They must certainly admit, if they are experienced and practical men, that the amount of trouble and consequent hazard must be greater where an entire installation is permitted in "plain iron or steel pipe" than in a case of a single wire passing through a short piece of "plain iron or steel pipe" in conjunction with brick walls or floor work.

"Jim Crow" has set forth in his letter another point which should have the attention of your readers, and, although it may not have been his intention to bring out the fact, it is true that under these rules, as well as under former rules of some of the associations, engineers, contractors and others may erect skeleton or solid iron or steel switchboards to which may be attached the usual appliances by the use of ordinary commercial forms of insulating materials. The rule as quoted reads: "Must be made of non-combustible material or hardwood in skeleton form, filled to prevent absorption of moisture."

In this connection it may be stated that one of the consulting engineers in this city suggested to a manufacturer of enameled apparatus that it would not be very long before certain classes of switchboards would be made completely of an iron or steel frame, and recommended to the manufacturer that he make provision for manufacturing skeleton frame work for switchboards, enameling the metal work, believing that time would eventually prove that such a board for low potential work would be permitted, and would be a cheaper form or construction, considering all the circumstances, than a marble one, and would outlive it beyond doubt.

Your readers will undoubtedly perceive that this engineer's recommendation was undoubtedly made in a spirit of bitter sarcasm, but he was undoubtedly well informed as to proposed new rules, as the inconsistencies of the latest rules prove; and it would not be surprising to the writer to actually hear of somebody making, or advising, an iron or steel frame switchboard, and quoting the National Board of Underwriters as an authority for such construction.

"Doe Bird" states that the main bone of contention is "simply as to which is the safer conduit for electrical conductors, insulated or uninsulated." I must differ from your correspondent, and offer criticisms on a different line at this time. I submit, that if "plain iron or steel pipes" are considered good and safe construction with both conductors of a circuit within them, then the insurance people certainly must, if they wish to be considered intelligent and fair-minded, permit the same class of construction as regards insulation, throughout any and all classes of work.

They cannot or should not expect to make suggestions treating conductors as "bare," formulate and distribute rules based upon such a suggestion and theory, conduct themselves throughout all the various forms of installation of wires and apparatus upon the theory of "bare" conductors, and then, with one sweep, wipe out all their rules and permit the use of conduits which under no circumstances, as evidenced by the various rules, and by the circular letter, can be treated as "bare."

If the underwriters are wise in their time, they will immediately withdraw their permit to use "plain iron or steel pipes," or else they will have to concede that their rules which allow other classes of installation are faulty, unjust and throw upon the engineer, contractor, and the owner a burden of expense which they have no right to ask of them. The insurance companies should also bear in mind the fact that the loss by fire is not paid by the insurance company, but by the premiums which come from the public, and consequently the public have just as much, if not more right, to dictate to the insurance companies what is proper and safe construction, as well as the insurance companies have to formulate and distribute rules and try to enforce them, when these rules are thoroughly inconsistent and cannot be lived up to.

VOL. XXIV. NEW YORK, AUGUST 19, 1897. No. 485.

AMERICAN ELECTRIC RAILWAY EQUIPMENT ABROAD.

WHEN the Central London Railway a few weeks ago gave its order for car, locomotive and electrical equipment to American manufacturers there was a considerable undercurrent of ill feeling noticeable in the comments of the English daily press, which took the stand that these orders ought to have gone to English firms. It is a satisfaction to note, however, that no such grumbling was manifested on the part of the English technical, electrical press. The reasons which dictated the giving of the order to America are well put in a recent interview with the secretary of the Central London Railway, published in the "Railway News," of London. That gentleman states that his company was influenced by the advice of the best electrical experts, who stated that the more extensive use of electric traction in the United States had brought the manufacture of plant and material to a higher pitch of perfection and to a much lower cost than they could be got at in England. Our tools and manufacturing machinery were much in advance of theirs, as was to be expected when the small amount of electrical traction construction in England is considered; and as it was the desire to equip the line in the very latest and the best manner, no recourse was left but to go to America for the material. This tells the story in a nutshell. American electric railway apparatus goes to England for the same reason that smaller American machine tools find a profitable market there. It represents, as do the latter, a product peculiar to American skill and experience, and as long as we keep in the van with these manufactures we will probably find a market for our goods. It must be apparent, however, that as time passes the English manufacturers will gain that experience which is now our particularly valuable stock in trade and that we cannot always hope to secure such sweeping orders as that for the Central London Railway equipment. But by keeping in advance we may still hope to stave off that day for some time to come. If England does not go extensively into electric railroading, her market for such electrical apparatus will be ours. Should she develop a large electric railway industry, she will certainly manufacture herself the supplies necessary. The present situation reflects on her slowness in making the change from horses and steam, and not on the ability of her electrical engineers and manufacturers.

THE X-RAY IN MEDICO-LEGAL QUESTIONS.

THE X-ray has already secured for itself a permanent place in the diagnosis of disease and in surgery, and has frequently been employed in medical-legal work to demonstrate before courts the existence of fractures or dislocations of bones. In a recent case, however, reported from Elmira, N. Y., counsel for an alleged murderer took the position that the victim met his death not by the bullet fired into his brain, but by the X-ray which was employed to locate the bullet. As no previous case of death from the X-ray has been reported, the ingenious plea of the prisoner's counsel will hardly be likely to have the desired effect on the jury. Still, the incident is worthy of note, as it emphasizes the fact that if the X-ray is not to fall into bad odor with the public and the courts, physicians and X-ray photographers generally will have to exercise the greatest care to prevent even the comparatively slight skin affections which have resulted from the injudicious use of the X-ray in the past. Apropos of this, attention is again called by Mr. Tesla to the precautions desirable in making X-ray photographs, and in an article which we print elsewhere in this issue he describes some new forms of X-ray tubes designed especially to avoid the evil effects noted in the past. Mr. Edison, who was probably the first to point out the ill effects of the ray, regards the dangers as being absurdly exaggerated.

LORD KELVIN.

IT is some thirteen years, we believe, since Lord Kelvin visited this country last, the occasion being the British Association meeting at Montreal and the Electrical Conference and Exposition at Philadelphia, in 1884. The arts of applied electricity have greatly grown in this country in the interval, and our distinguished visitor will doubtless find much to interest and please him. The same period has, however, witnessed the steady growth of Lord Kelvin's own work and the firmer establishment of his own great fame and reputation; and American electricians are glad to extend to him hearty congratulations not only upon his long years of high public service as physicist and inventor, but upon the honors that of late have been poured upon him. With this official recognition of Lord Kelvin's work goes a recognition of electrical advance, and the honors are such, therefore, as we can all share in. And what we say of the welcome now accorded Lord Kelvin here, applies equally to the other well known leaders in electrical science and application who attend the British Association meeting at Toronto this week. We American electrical engineers are all delighted to see our brethren from across the sea and trust that their stay may be prolonged.

THE MARCONI WIRELESS TELEGRAPH AS A COMMERCIAL INSTITUTION.

WIRELESS telegraphy has reached the commercial stage in London to the extent of a capitalization of the Marconi system in the sum of £100,000 in what the London "Electrician" calls "handy £1 shares." With the air of the Scotchman contemplating the marriage feast vessel in St. Ursula's our careful contemporary concedes that Signor Marconi's system "may" have some original features; but it has its doubts, and after dividing the poor fellow's substance between Maxwell, Hertz, Branly and Lodge, it inquires pessimistically of what commercial use is wireless telegraphy going to be anyway? We are loth to add to the decimating criticism of our friends over the water upon this organization of "Earth Wobbling" elements, and feeling sure that the "handy £1 shares" were snapped up long before the "Electrician's" frosty radiations reached the pocket coherer of the British investor, we would point out that the financial editor in Salisbury Court, E. C., overlooked one very important prop upon which Signor Marconi's edifice of borrowed equations, telepathized experiments, kodaked radiations and long range coherency seems to rest, viz., the "tapper" for shaking the powder in the coherer, so as to de-cohere it after a signal current has caused it to cohere. Without this shaking up the receiver would keep the local circuit closed, or cause it to "stick." In his American patent just issued all of Signor Marconi's fifty-six claims include the combination of "a means for shaking the powder" or contact of the receiver. Now it appears that at about the beginning of Hertz's experiments the advantages of communicating vibrations to a telegraph receiver for the purpose of preventing cohesion of the contacts were discovered by another inventor, as disclosed in British patent No. 21,629, 1893, for improvements in cable and submarine telegraphy, issued to Delany. It shows a vibrator "for preventing sticking or adherence of the movable contact arm of the main receiver or relay to its contacts, from any cause whatever." . . . "When the main line current ceases, the vibration prevents any welding or other bond of cohesion between the contacts." . . . "These freeing vibrations may be created in any suitable way, electrical, mechanical or otherwise, and, of course, may be applied to a receiver in a main line current, a local circuit, or to the contact or limits of any delicately actuated arm of telegraphic receiving instruments." Still, if Signor Marconi can organize Maxwell's equations, Hertz's experiments, Branly's radiator, Lodge's coherer and

Delany's agitator so as to find St. Paul's from the Eiffel tower in a London fog, he is a great man, and we predict that the "handy £1 shares" will command a premium calculated to fill skeptics with chagrin. Only last week we printed the text of the original, modest little circular issued by Messrs. Hubbard and Watson as to the use of the telephone, twenty years ago when few people could see any use for it and when the stock went begging. Various uses have already been suggested for the wireless telegraph, and reading now of the cut wires of the British troops on the Afghan borderland and their dependence on heliographs liable to be obscured any moment by smoke, accidental or intentional, we could not but think that "scientific frontiers" might well be strengthened by wireless telegraphs.

WHEN IS A STREET RAILROAD NOT A STREET RAILROAD?

THIS rather perplexing question has just been decided in Ohio by Judge Neilan in an action brought against the Miami Valley Traction Company, by steam railroad rivals, to prevent it from building its line from Hamilton, Ohio, out through Warren County. Various grounds of objection were raised against the right of the County Commissioners to grant an absolute right of way on highways to a street railway carrying passengers, freight, mail and express. The court first of all found nothing unconstitutional in the law under which the commissioners had granted right of way, and then justified their action as well within the scope of its provisions. It saw nothing wrong in a longitudinal occupation for public service of a part of the highway, and did not consider the use of the term "electric street railways" as in any wise a restriction. We think the court was justified in refusing to sanction a narrow interpretation of the word "street" and in declining to limit transportation on "streets" or highways to horses because no better means was known in days gone by. In this case the track is at the side of the road and conforms with it in grade, so that the entire highway can still be used except as the car is passing. Moreover, as population will at once grow up along the highway, it will become more of a "street" than ever. Turning to the matter of freight, etc., the court remarked: "To say that it is constitutional for a farmer or his wife to ride to the nearest market town, but it is unconstitutional for him to take a quarter of beef, or his wife to take a basket of eggs, or a roll of butter to market; or, if instead of going themselves, they send those articles on this railroad—is it seems to the court an absurdity." The judge went on to say also that even if the farmer hitched a motor car to his wagon of wheat, instead of hauling it along the highway with a team of horses, it would not be unconstitutional, but "the very purpose" for which the highway was first laid out. So think we, feeling at the same time that this decision is but another sign of the profound changes going on in old-fashioned ideas as to what was a railroad, or street railroad, and what was not. This decision is certainly one of great interest to contractors and to security holders in general, and deserves note by all engaged in railway work.

MR. MOORE AND HIS CRITIC.

IN its last issue the "Electrical Review" returns to the attack on Mr. Moore's system of vacuum tube lighting, and continues its criticisms of the articles which have appeared in The Electrical Engineer descriptive of Mr. Moore's system. It ends up by asserting that even if Mr. Moore's system should prove successful there would be nothing new in it. So far as the criticisms on The Electrical Engineer's statements are concerned, we stand by every word we have thus far printed. Where figures were given they were based on facts, and as for the rest, our aim has been to treat Mr. Moore fairly and to give him, as we would any other struggling inventor, such encouragement as lay in our power,—a course which we shall continue to pursue. As to the novelty of Mr. Moore's devices, that is a question which we have never raised, nor have we investigated it as patent experts in the slightest degree. All we know is that the world has for some time past been seeking a cold, white light and that Mr. Moore notably is trying to give it what it wants. Whether his means are old or new is of no consequence to us whatever; we are perfectly well satisfied to let Mr. Moore himself take care of that part of the question. The very fact that our contemporary has been compelled to avail itself of this argument indicates the weakness of the stand it has taken in this controversy. In its last utterances, moreover, our contemporary has, we are sorry to note, introduced remarks quite as irrelevant to the real question, as though a public speaker were interrupted with criticisms of his height or the fit of his clothes. Such offensive and vulgar personalities in debate are usually intended to close a discussion forcibly or compel its continuance on similar lines of objurgation. In this case, if such be the intention of our esteemed contemporary, we must decline to discuss the merits of any invention on the basis of our own or any other journal's circulation. If our contemporary had no such intention of befogging the issue, we beg to assure it of our highest consideration.

WASTED CURRENT IN ARC LAMPS.

EVER since arc lamps have been run on constant potential circuits, the practice has been open to the just criticism that it involved an appreciable loss of energy consumed in the resistance invariably accompanying the lamp. This resistance was necessary to make up for the difference in potential between the lamp terminals and that of the feeding circuit, as well as to "steady" the arc. Even with two ordinary arc lamps in series, an appreciable percentage of the current is wasted, and even the high voltage enclosed arc does not overcome the difficulty. Allowing a loss of, say, 25 per cent. of the energy supplied to the lamps, it is apparent that an installation of only a dozen arc lamps means a decided loss of energy. To prevent this constant loss it was proposed some five years ago by Prof. Heim to substitute low voltage incandescent lamps for the dead resistance, and at least one installation of this kind was carried out in Berlin. We are not informed whether this plant worked satisfactorily or not, but the chances are that it did not, for the obvious reason that the fluctuations of potential at the terminals of even the best arc lamps would be fatal to the life of the incandescent lamps in the same circuit, or, at any rate, would cause such marked fluctuation in candle-power as to make them unserviceable. The economical Germans are apparently still bent on preventing this loss, for we note in a German contemporary an article in which the writer proposes to absorb the wasted energy by charging storage batteries from which incandescent lamps, or electric heating devices, or fans can be fed at any desired time of the day. There is apparently nothing impossible in the carrying out of this suggestion, and it might be worth a trial where a large number of arc lamps are connected to incandescent circuits. There is, however, one doubtful point which suggests itself in this connection, and that is whether the arc lamps themselves will work properly under the conditions assumed. As is well known, arc lamps on constant potential circuits require a "steadying" resistance, and it would remain to be seen whether the counter e. m. f. of the storage battery would act in the same way as a dead resistance so far as the arc is concerned. We must confess to some doubts on this score. Nevertheless, the matter of the wasted energy in constant potential arc lamps is well worth further study, now that the enclosed arc has given that type of lamp another decided impetus.

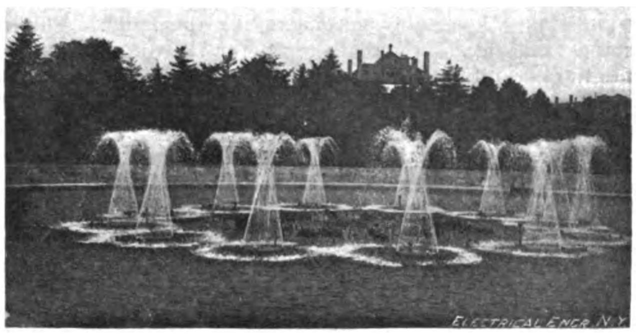
CLOSING A CHICAGO MUNICIPAL SHOP.

CHICAGO has of late been, as a city, under the necessity of saving money wherever possible, and hence a great many old leaks are being stopped. If the city would go out of industrial business altogether it would probably be able to reduce taxes materially, but that is hoping for too much. We are pleased to note, however, that Mr. E. B. Ellicott, the new city electrician, has taken one bull by the horns in closing the city electrical repair shop, after receiving a report from the foreman, which at once convinced him that "a large sum of money could be saved by closing the repair shop and having the repair work of the department done under contract." If Mr. Ellicott would follow this out logically, and take the city out of the electric lighting business, he would save still more money and add further lustre to Mayor Harrison's administration. It is rarely that one strikes such a frank admission of the expensiveness of municipal ownership. Within the past week, three reports as to city plants have passed through our hands, in each of which a large sum of money is called for to extend the plant, so that it can be made satisfactory and meet the demands on it. Yet when the original plants were put in, the tune was very different. Each plant was going to pay for itself in a year or two and provide for extensions out of the profits. But municipal plants in reality don't work that way.

ELECTRIC LIGHTING

THE ELECTRIC FOUNTAIN AT THE PROSPECT PARK PLAZA, BROOKLYN, N. Y.

ANOTHER electric fountain has been added to the list which already is becoming a long one, of such installations in this country. In its issue of May 26 last The Electrical Engineer gave some details as to the fountain proposed for the plaza outside the main entrance to Prospect Park.



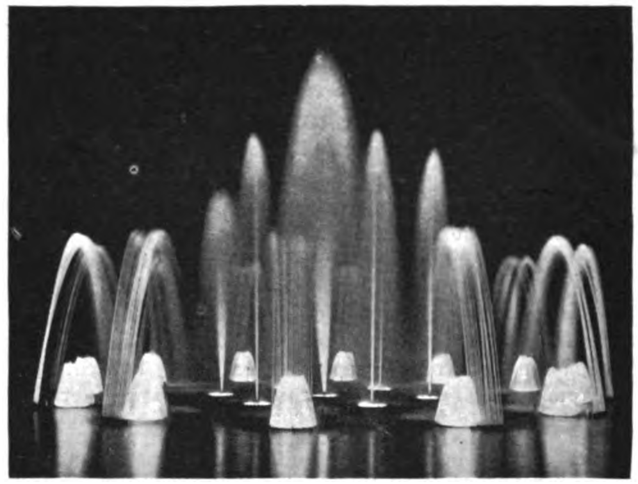
DAY EFFECT, BROOKLYN ELECTRIC FOUNTAIN.

Brooklyn, and it was stated that the work had been entrusted to Mr. F. W. Darlington, the consulting electrical engineer, of Philadelphia. The plans have now been successfully carried out, and a few details may, therefore, be given of the operation of the plant.

The Prospect Park fountain stands in the center of the plaza, and its jets rise at the point where the center lines

BIRD'S-EYE VIEW OF THE ELECTRIC FOUNTAIN, PROSPECT PARK PLAZA, BROOKLYN, N. Y.

meet of the two great converging avenues which lead to that part of the park. At this same spot there stood for thirty years or so a fountain built by C. C. Martin, the present Chief Engineer of the Brooklyn Bridge, but that fountain was one of the high cascade style and would have obscured the view of the new white arch and decorative columns which now mark this entrance to the park. All of the old fountain has been removed and the pool for the new fountain now lies almost level with the curb. No part of it interferes with the view as one approaches the plaza, as shown in one of the engravings herewith. The arch and the columns back of it can be seen for half a mile down these avenues, and when the new fountain plays its waters will be seen with these noble features for a background. Simple grass plots border the new fountain, and all around on three sides the ground rises



ONE OF THE EFFECTS, BROOKLYN FOUNTAIN.

from it, so that tens of thousands of persons are able to view it as in an amphitheater.

The pool lies within a broad sidewalk and about its immediate edge there is nothing but an ogee moulding of granite which rises less than two feet above the level of the walk. The basin is a perfect circle, 120 feet in diameter. One of our illustrations shows its position. Within the walls drop straight down about four feet and from the edges the bottom slopes away gradually, leaving the waters shallow at the edges. When the water is at the full height only a few nozzles rise above it near the center.

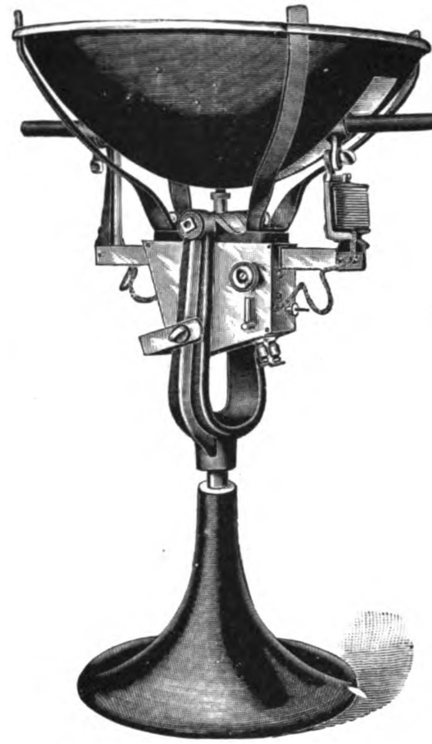
At the side of the basin nearest to the avenues is a gateway. Through this a part of the waters are let out when the more intricate effects are to be produced. When the waters are lowered six inches or so, the pipes and

jets are disclosed. The main features of these are nineteen glass-topped funnels, or holophotes, which rise even with the surrounding waters. It is through these that the colored lights are projected from a working chamber below. These funnels are arranged in two concentric circles, with one holophote in the exact center of the fountain. In the first circle are six funnels and in the second are twelve. From the center of this middle funnel rises a pipe with a 1½-inch nozzle, which projects a central geyser jet high in the air. Around the edge of this funnel are seventeen smaller jets. In straight lines one on each side of this funnel are jets which throw up fans of water, and running around in circles, one just within and the other just outside the first circle of funnels, are many jets, which project circular walls of spray over that line of funnels. Each one of the six funnels of the inside circle has a center jet, throwing an inch stream, and each of these funnels has also two lines of small jets surrounding it. Between these funnels are straight lines of small jets, rayed out from the center of the fountain, forming a six-pointed star. In each of these lines there are forty jets. Twenty of these throw their streams to the right and twenty to the left, bringing their waters over the lights that will stream upward from the funnels. Each of the twelve funnels of the outer row has a fringe of seventy-four jets, which form sheaves of water, and lying just within this outer circle of funnels are twelve large pipes which project fancy streams of four different kinds arranged alternately around the circle. Three of these form umbrellas of water, three throw up fountains of rose spray, three are whirling jets, and three are ball nozzles, which make

ONE OF THE EFFECTS, BROOKLYN FOUNTAIN.

globular showers of water. Twelve more nozzles, each ¾ of an inch in diameter, lie just outside these outer funnels, and these throw up solid streams, which lean inward toward the center geyser. Outside of these, and forming the extreme circle of jets, are twelve straight lines of tiny nozzles, each of which throws up sixteen streams of water in straight ribbons. These ribbons also lean inward, so as to bring their waters over the funnels of light, and when they are playing toward the central geyser, and each is illuminated in different colors, the effect resembles a May pole with its variegated ribbons. Altogether there are nearly 2,000 jets in the fountain, and when all of them are in use it is estimated that it will take 100,000 gallons of water an hour to operate them. A row of white electric lights around the inside wall of the basin will illuminate the waters at ordinary times.

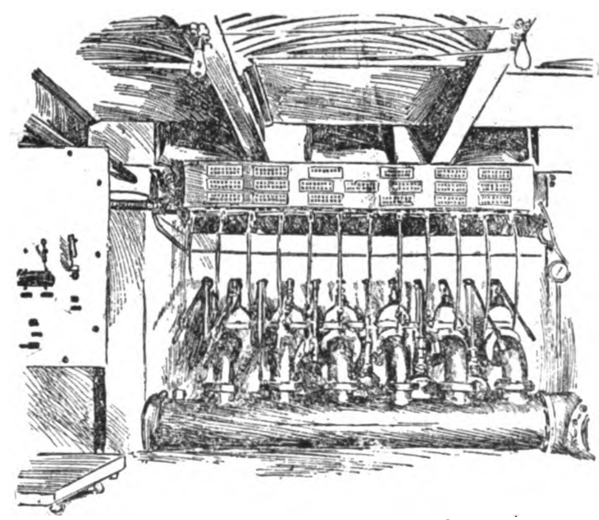
Under the basin and under the grass plot between it and the arch is the operating mechanism. A dozen pipes lead from the adjacent city water tower and reservoir to the fountain work in the center. Two of these pipes are only two inches in diameter, but the other ten are each six inches in diameter. The central display is divided into twelve distinct parts, and each of these is supplied with water from one of these pipes, and the water for each is controlled by a valve in the operating chamber. In the side of the basin next the arch are three glass windows. The operator who controls the jets and the colored lights stands underground in front of those windows and plays the fountain. The operating chamber lies directly under the center of the basin. It is octagon in shape and is forty-five feet across. Its roof is upheld by steel beams and columns and is formed of arches of corrugated steel, cement and asphalt. Through this roof run the nineteen holophotes, each 22 inches in diameter, and covered with plate glass. Under each funnel stands a powerful electric searchlight, fed by the 500-volt current of the trolley



ARC PROJECTOR UNDER FOUNTAIN.

wires. Hung from the ceiling, beside each funnel is a rack of eight round steel frames, each of which contains a colored glass the size of the funnel. In these frames are glasses of the seven colors of the rainbow and one of black. Attached to an arm on each frame is a lever which runs to an air cylinder, and the arms are operated by an automatic electric air compressor. Electric wires run to valves on each of these cylinders, and the pushing of buttons in the operating room lets the air into the cylinders or out again and so swings the discs of colored glass between the searchlights and the funnels or back again.

One man attends to the searchlights, and the only other per-



OPERATING ROOM, BROOKLYN PLAZA FOUNTAIN.

son needed is the operator. Where he stands looking out of his windows he faces a row of twelve levers, each of which controls the water to one set of the fountain jets. In front of him is also a long board, on which are arranged nineteen sets of push buttons—one set for each funnel. There are two rows of eight push buttons in each set. The upper row has each button colored to match the colored glass disc which it con-

trols. Those in the lower row are all white. When the operator touches a colored button, the disc of that color is turned over the searchlight. When he touches the white button beneath the disc is turned back again.

Behind the operator is a pit prepared for an electric pump, which will eventually be put in to furnish a much higher pressure for the fountain than can be got from the city mains, and to use the water over and over again. This pump will cost about $5,000, and no appropr'ation has yet been made for it. When it is in use the water can be sent to the fountain at a pressure of 150 pounds to the inch, instead of the 30 pounds now available.

The contract price for the fountain was $24,500. The current on the fountain is supplied free by the Nassau and Brooklyn Heights trolley companies, which have tapped their 500-volt trolley mains for the purpose. At the present time the fountain is illuminated on Wednesday and Saturday nights, when, of course, the roads benefit in turn by the large crowds of spectators attracted to the plaza by the brilliant spectacle.

The arc lamps used under the fountain in Brooklyn to illuminate the jets of water were made by J. B. Colt & Co., and are similar to theater projection lamps with the exception of being arranged to carry a heavy current of 40 amperes instead of 20. The insulation of all parts of the lamps is much heavier, as it has to stand 500 volts with the return wire grounded. All the insulation is thick sheets of mica, and no part of the lamp is connected with the current except the short carbon holders, not even the racks that support the holders. To still further insulate the lamps the heavy iron bases are supported on boards which in turn stand upon insulators. The type of lamp is shown herewith. Six lamps are run in series, there being three circuits, one of which has seven lamps in series, making in all nineteen lamps. Each lamp takes 45 volts; therefore, six lamps take 270 volts, leaving 230 volts surplus, which is taken up in an adjustable rheostat, this latter regulating the current, so that if the voltage of the mains drops to 300 volts the rheostat is nearly all cut out and the lamps are not reduced in brilliancy.

A strong spring movement brings the carbons together in each lamp, the regulation being performed by a shunt magnet. Under these conditions the lamps feed as well on 15 or 20 amperes as on 40. The reflectors used are polished metal parabolic reflectors, 20 inches in diameter. The beams of light have been so arranged by Mr. E. P. Hopkins, electrician for J. B. Colt & Co., as to form a very high cone of light, each beam being slightly inclined toward the center, and in this way follows the jet of water. In order to obtain a steady light from carbons in a horizontal position, the regulation must be very sensitive and feed often, but slowly, producing almost a continuous feed, but at the same time it must rest for some time, in order to burn off the lower edge of the carbon, or any "mushrooms" that sometimes form, from apparently no cause whatever. The shunt regulation of these lamps accomplishes this very successfully.

As already stated, the fountain has been designed and built by Mr. F. W. Darlington, the work of actual construction being done by the Wilson & Baillie Manufacturing Co., for whom Mr. J. W. Wilson is the electrical engineer. Mr. C. C. Martin has acted as the consulting engineer for the city. The structural ironwork and piping was furnished by Benjamin F. Shaw Company, and the air tank, etc., by the Hunt Air Brake Company; the air valve control mechanism being made by the Cleverly Electrical Works, of Philadelphia. As already noted above, the lamps are those of J. B. Colt & Co. The switchboard is of white marble, with knife switches, and Weston indicating instruments.

ELECTRIC LIGHTING AND GAS CONSOLIDATION IN NEW JERSEY.

The People's Electric Light and Power Company and the Newark Gas Company, each having a capital of $5,000,000, and controlling most of the lighting interests in Essex, Hudson, Bergen, Passaic and Union counties, have perfected a plan of consolidation, with a capital of $15,000,000. The United Gas Improvement Company, of Philadelphia, which controls many of the gas and electric light and power companies of South Jersey, is interested in the deal. Some of the promoters admit that the connection of the latter concern means the ultimate consolidation of many of the gas and electric power companies of the State, with an aggregate capitalization of $50,000,000.

VICTORIA, TEX.—The Victoria Light, Power and Ice Company, which has a Westinghouse alternating plant, is in the market for a high speed engine of from 100 to 125 h. p. Mr. L. L. Stephenson is the manager and superintendent.

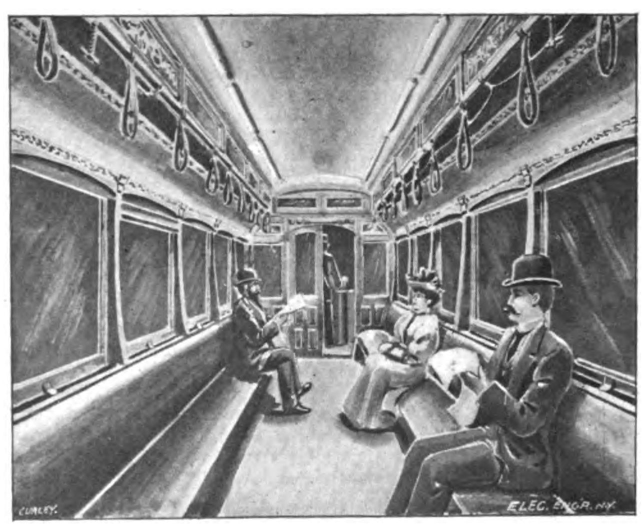
MOORE VACUUM TUBES FOR STREET AND CAR LIGHTING.

IN the accounts we have given up to the present of Mr. D. McFarlan Moore's system of vacuum tube lighting, the tubes were employed for interior illumination. Looking toward the future, however, Mr. Moore has recently tried some experiments in outdoor vacuum tube illumination, which lead him to the belief that such work is in every way practicable.

Street Lighting by Vacuum Tubes from Railway Circuits.

In a recent out-of-door experiment of this kind, it was found that with the light of only one tube the seconds' hand of a watch could be read at a distance of 60 feet. The tube in question was similar to those Mr. Moore has used in previous experiments, being about 7 feet long and 2 inches in diameter. In this case the upper half of the tube was painted white, so as to act as a reflector, with the result that the light was cast downward affording an absolutely uniform distribution.

Mr. Moore believes that the streets through which electric railway lines pass present special facilities for carrying out



Street Car Lighting by Vacuum Tubes.

such a plan of illumination. The tubes could be strung between the poles in the manner illustrated in the accompanying engraving, Fig. 1, the current being derived from the railway circuits. Though the engraving is only intended as a fancy sketch, Mr. Moore is so thoroughly impressed with the feasibility of the plan that he has actually worked out many of the details to insure continuous operation under all conditions of weather. He has already determined the fact that water on the tube interferes in no way with its action.

For electric car lighting Mr. Moore also believes his system well adapted. Besides lighting the interior in the manner shown in the sketch, Fig. 2, the names of the streets can be outlined on front and sides of the car, so that colored signal lights will no longer be necessary.

THE ZAMEL ARC LIGHT METER.

THE Zamel Arc Light Meter Company, 266 Blue Island avenue, Chicago, have just brought out a new device for the purpose of timing the use of arc lights. They claim their device to be reliable in every way, and that it will positively start the clock movement whenever the current is turned into the meter and lamps, and will also stop the clock when the current is turned off.

Central stations may derive benefit by the adoption of this meter in various ways by having the customer turn the light on or off as it is needed, thereby saving the salary of a man to patrol circuits to shut off 10 o'clock or other earlier lights; they are also enabled to place new contracts with parties who

THE ZAMEL ARC LIGHT METER.

would not go on a monthly schedule. The manufacturers say that this meter or timer has been tested by several companies and found to operate in a perfectly reliable manner.

The meter is a simple device, consisting of a balance wheel on a shaft on which is also placed a toothed lever which works a cogwheel that serves to start and stop the clockwork movement which registers the length of time during which the arc lights are being used. The front of the instrument has a face similar to a clock's on which are shown the number of hours that the lights are in operation. All parts of the instrument are mounted on slate and perfectly insulated.

The clock will indicate 144 hours. The hand on large dial measures up to twelve hours and shows quarter hours. Each number on the small dial represents one round of the large dial, or twelve hours; one revolution of the small dial indicates 144 hours.

LIGHTING CIRCUITS—LIGHTNING CONDUCTORS.

BY BINGHAM WOOD.

IN many cases the introduction of electric lighting into buildings has been followed by an increase of the insurance rate. The following incident will go to show that lighting wires are in some cases a protection rather than a risk in buildings.

During a heavy electrical storm some days since, the largest hall that the town of Egg Harbor City, N. J., can boast of was struck by lighting and the only apparent effect was the lights all going out.

Directly over the stage, which is stocked with a large quantity of inflammable material in the shape of scenery and other property effects, is a square tower surmounted by a flagpole. In this tower is placed the converter supplying the building with current.

The bolt struck the flagpole and followed down to one of the rafters, completely shattering it. From here it glanced over to the converter, through it to the line and ground through the arresters.

As the building is entirely of wood and has no pipes or other ironwork in it, and is not protected by lightning rods, it is fair to suppose that but for the presence of this converter the bolt would have taken a direct course to the ground through the stage, and would in all probability have ignited some of the scenery, and there would have been no possible chance of saving the building.

ENLARGEMENT OF NIAGARA HYDRAULIC POWER PLANT.

Three important contracts have been awarded by the Niagara Falls Hydraulic Power and Manufacturing Company in connection with the enlargement of its big power house below the bank. The contracts were for the structural steel for the interior of the power house extension and involve a large sum in the cost of its manufacture. The contracts awarded are as follows:

Structural steel work, the Variety Iron Company, of Cleveland; for all valves required, R. D. Wood & Co., of Philadelphia; the penstock, Struthers, Wells & Co., of Warren, Pa. The penstock which will supply the water for the additional turbines and dynamos will be 15 feet in diameter and 300 feet long. It is to be one of the largest penstocks ever built, and will weigh 300 tons complete. The capacity of the penstock will be sufficient to develop 10,000 h. p.

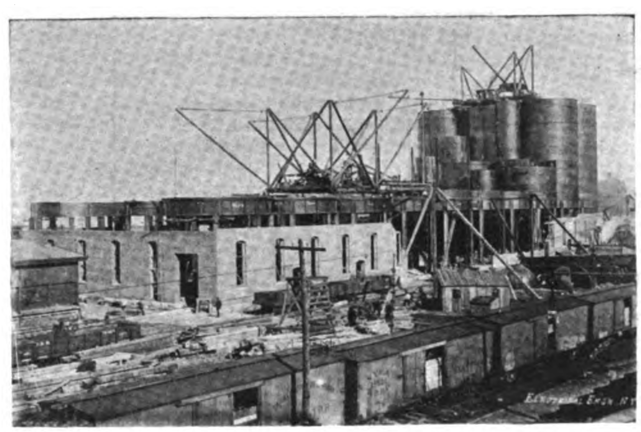
The power house building is now complete and the Power Company is pushing the interior as rapidly as possible. The turbines and dynamos will be of the same design as those in the present station.

GREAT NORTHERN GRAIN ELEVATORS IN BUFFALO.

BY ORRIN E. DUNLAP.

THE strength that President James Hill gives to the Great Northern Railway and Steamship Company is well portrayed in the magnificent new steel grain elevator that he is building in Buffalo. It shows that he is determined the companies he represents shall keep well abreast of the times. This elevator will be the greatest one of its kind in the country, and it will be operated by electric power from Niagara. This power has already been contracted for, and will be supplied through the Cataract Power and Conduit Company, distributing agents for Niagara power in Buffalo.

The elevator is to be known as the Great Northern, and its grain bins are to be huge steel cylinders. There will be three rows of these bins, ten in each row, or thirty in all. Each bin will have a capacity of about 100,000 bushels, making the total capacity of the elevator about 3,000,000 bushels. In order to support the immense weight of the bins when full, it was necessary that the foundation should be especially solid, and in order to secure solidity it was necessary to go down about 60 feet. On the foundation so laid a structure of steel



GREAT NORTHERN GRAIN ELEVATOR, BUFFALO, N. Y.

was erected, and on this steel work rest the bins. Each of the bins is about 84 feet high and 38 feet in diameter. Between the rows of large bins are smaller bins about 15 feet in diameter, and it is in these smaller bins that the grain is first put when taken from the vessels, after which it is placed in the large bins.

In the accompanying illustration the bins at the far end are shown at their full height, while the structural steel work beneath the bins is also well displayed. When the bins are completed the brick walls will be carried up around them, and this will give the elevator much the appearance of other buildings, hiding the modern construction of the bins. It is expected to have the elevator completed by next spring.

ON THE SOURCE OF ROENTGEN RAYS AND THE PRACTICAL CONSTRUCTION AND SAFE OPERATION OF LENARD TUBES.[1]

BY NIKOLA TESLA.

As will be remembered, in the first announcement of his discovery, Röntgen was of the opinion that the rays which affected the sensitive layer emanated from the fluorescent spot on the glass wall of the bulb; other scientific men next made the cathode responsible; still others the anode, while some thought that the rays were emitted solely from fluorescent powders or surfaces. My own experiments led me to recognize that, regardless of the location, the chief source of these rays was the place of the first impact of the projected stream of particles within the bulb. This was merely a broad statement, of which that of Prof. Röntgen was a special case, as in his first experiments the fluorescent spot on the glass wall was, incidentally, the place of the first impact of the cathodic stream. Investigations carried on up to the present day have only confirmed the correctness of the above opinion, and the place of the first collision of the stream of particles—be it an anode or independent impact body, the glass wall or an aluminum window—is still found to be the principal source of the rays. But, as will be seen presently, it is not the only source.

Since recording the above fact my efforts were directed to finding answers to the following questions: First, is it necessary that the impact body should be within the tube? Second, is it required that the obstacle in the path of the cathodic stream should be a solid or liquid? And, third, to what extent is the velocity of the stream necessary for the generation of and influence upon the character of the rays emitted?

In order to ascertain whether a body located outside of the

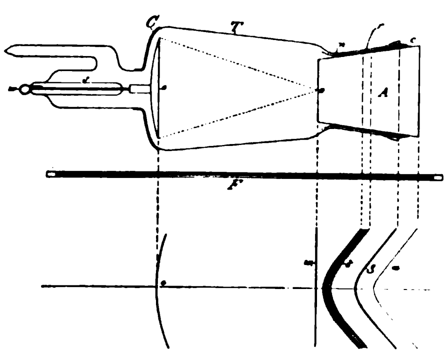


Fig. 1.

tube and in the path or in the direction of the stream of particles was capable of producing the same peculiar phenomena as an object located inside, it appeared necessary to first show that there is an actual penetration of the particles through the wall, or otherwise that the actions of the supposed streams, of whatever nature they might be, were sufficiently pronounced in the outer region close to the wall of the bulb as to produce some of the effects which are peculiar to a cathodic stream. It was not difficult to obtain with a properly prepared Lenard tube, having an exceedingly thin window, many and at first surprising evidences of this character. Some of these have already been pointed out, and it is thought sufficient to cite here one more which I have since observed. In the hollow aluminum cap, A, of a tube, as shown in diagram Fig. 1, which will be described in detail, I placed a half-dollar silver piece, supporting it at a small distance from and parallel to the window or bottom of the cap by strips of mica in such a manner that it was not touching the metal of the tube, an air space being left all around it. Upon exciting the bulb for about 30 to 45 seconds by the secondary discharge of a powerful coil of a novel type now well known, it was found that the silver piece was rendered so hot as to actually scorch the hand; yet the aluminum window, which offered a very insignificant obstacle to the cathodic stream, was only moderately warmed. Thus it was shown that the silver alloy, owing to its density and thickness, took up most of the energy of the impact, being acted upon by the particles almost identically as if it had been inside of the bulb, and, what is more, indications were obtained, by observing the shadows, that it behaved like a second source of the rays, inasmuch as the outlines of the shadows, instead of being sharp and clear as when the half-dollar piece was removed, were dimmed. It was immaterial for the chief object of the inquiry to decide by more exact methods whether the cathodic particles actually penetrated the window or whether a new and separate stream was projected from the outer side of the window. In my mind there exists not the least doubt that the former was the case, as in this respect I have been able to obtain numerous additional proofs.

I next endeavored to ascertain whether it was necessary that the obstacle outside was, as in this case, a solid body, or a liquid, or broadly, a body of measurable dimensions. I observed accidentally what is illustrated in Fig. 1. The diagram shows a Lenard tube of improved design, consisting of a tube, T, of thick glass tapering toward the open end, or neck, n, into which is fitted an aluminum cap, A, and a spherical cathode, e, supported on a glass stem, s, and platinum wire, w, sealed in the opposite end of the tube as usual. The aluminum cap, A, as will be observed, is not in actual contact with the ground glass wall, being held at a small distance from the latter by a narrow and continuous ring of tinfoil, r. The outer space between the glass and the cap, A, is filled with cement, c, in a manner described below. F is a Röntgen screen such as is ordinarily used in making the observations.

Now, in looking upon the screen in the direction from F to T, the dark lines indicated on the lower part of the diagram were seen on the illuminated background. The curved line, e, and the straight line, w, were, of course, at once recognized as the outlines of the cathode, e, and the bottom of the cap, A, respectively, although, in consequence of a confusing optical illusion, they appeared much closer together than they actually were. For instance, if the distance between e and o was 5 inches, these lines would appear on the screen about 2 inches apart, as nearly as I could judge by the eye. This illusion may be easily explained and is quite unimportant, except that it might be of some moment to physicians to keep this fact in mind when making examinations with the screen as, owing to the above effect, which is sometimes exaggerated to a degree hard to believe, a completely erroneous idea of the distance of the various parts of the object under examination might be gained, to the detriment of the surgical operation. But while the lines, e and w, were easily accounted for, the curved lines, t, g, a, were at first puzzling. Soon, however, it was ascertained that the faint line, a, was the shadow of the edge of the aluminum cap, the much darker line, g, that of the rim of the glass tube, T, and t the shadow of the tinfoil ring, r. These shadows on the screen, F, clearly showed that the agency which affected the fluorescent material was proceeding from the space outside of the bulb towards the aluminum cap, and chiefly from the region through which the primary disturbances or streams emitted from the tube through the window were passing, which observation could not be explained in a more plausible manner than by assuming that the air and dust particles outside, in the path of the projected streams, afforded an obstacle to their passage and gave rise to impacts and collisions spreading through the air in all directions, thus producing continuously new sources of the rays. It is this fact which, in his recent communication before mentioned, Röntgen has brought out. So, at least, I have interpreted his reported statement that the rays emanate from the irradiated air. It now remains to be shown whether the air, from which all foreign particles are carefully removed, is capable of behaving as an impact body and source of the rays, in order to decide whether the generation of the latter is dependent on the presence in the air of impact particles of measurable dimensions. I have reasons to think so.

With the knowledge of this fact we are now able to form a more general idea of the process of generation of the radiations which have been discovered by Lenard and Röntgen. It may be comprised in the statement that the streams of minute material particles projected from an electrode with great velocity in encountering obstacles wherever they may be, within the bulb, in the air or other medium or in the sensitive layers themselves, give rise to rays or radiations possessing many of the properties of those known as light. If this physical process of generation of these rays is undoubtedly demonstrated as true, it will have most important consequences, as it will induce physicists to again critically examine many phenomena which are at present attributed to transverse ether waves, which may lead to a radical modification of existing views and theories in regard to these phenomena, if not as to their essence, so, at least, as to the mode of their production.

[1]From The Electrical Review.

My effort to arrive at an answer to the third of the above questions led me to the establishment, by actual photographs, of the close relationship which exists between the Lenard and Röntgen rays. I prepared a tube in the manner described by Lenard in his first classical communication on this subject. The tube was exhausted to a moderate degree, either by chance or of necessity, and it was found that, when operated by an ordinary high-tension coil of a low rate of change in the current, no rays of any of the two kinds could be detected, even when the tube was so highly strained as to become very hot in a few moments. Now I expected that, if the suddenness of the impulses through the bulb were sufficiently increased, rays would be emitted. To test this I employed a coil of a type which I have repeatedly described, in which the primary is operated by the discharges of a condenser. With such an instrument any desired suddenness of the impulses may be secured, there being practically no limit in this respect, as the energy accumulated in the condenser is the most violently explosive agent we know, and any potential or electrical pressure is obtainable. Indeed, I found that in increasing the suddenness of the electromotive impulses through the tube—without, however, increasing, but rather diminishing the total energy conveyed to it—phosphorescence was observed and rays began to appear, first the feebler Lenard rays and later, by pushing the suddenness far enough, Röntgen rays of great intensity, which enabled me to obtain photographs showing the finest texture of the bones. Still, the same tube, when again operated with the ordinary coil of a low rate of change in the primary current, emitted practically no rays, even when, as before stated, much more energy, as judged from the heating, was passed through it. This experience, together with the fact that I have succeeded in producing by the use of immense electrical pressures, obtainable with certain apparatus designed for this express purpose, some impressions in free air, have led me to the conclusion that in lightning discharges Lenard and Röntgen rays must be generated at ordinary atmospheric pressure.

I have already described the form of tube illustrated in Fig. 1, and in Fig. 2 another still further improved design is shown. In this case the aluminum cap, A, instead of having a straight bottom as before, is shaped spherically, the center of the sphere coinciding with that of the electrode, e, which itself, as in Fig. 1, has its focus in the center of the window of cap, A, as indicated by the dotted lines. The aluminum cap, A, has a tinfoil ring, r, as that in Fig. 1, or else the metal of the cap is spun out on that place so as to afford a bearing of small surface between the metal and the glass. This is an important practical detail as, by making the bearing surface small, the pressure per unit of area is increased and a more perfect joint made. The ring, r, should be first spun out and then ground to fit the neck of the bulb. If a tinfoil ring is used instead, it may be cut out of one of the ordinary tinfoil caps obtainable in the market, care being taken that the ring is very smooth.

In Fig. 3 I have shown a modified design of tube. This, as will be observed, is a double focus tube, with impact plates or iridium alloy and an aluminum cap, A, opposite the same. It will be noted that the aluminum caps in the tubes described are fitted inside of the necks and not outside, as is frequently done. Long experience has demonstrated that it is practically impossible to maintain a high vacuum in a tube with an outside cap. The only way I have been able to do this in a fair measure is by cooling the cap by a jet of air, for instance, and observing the following precautions: The air jet is first turned on slightly and upon this the tube is excited. The current through the latter, and also the air pressure, are then gradually increased and brought to the normal working con-

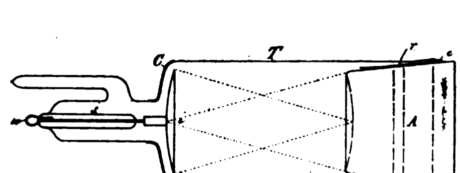

FIG. 2.

dition. Upon completing the experiment the air pressure and current through the tube are both gradually reduced and both so manipulated that no great differences in temperature result between the glass and aluminum cap. If these precautions are not observed the vacuum will be immediately impaired in consequence of the uneven expansion of the glass and metal.

With tubes, as those described, it is quite unnecessary to observe this precaution if proper care is taken in their preparation. In inserting the cap the latter is cooled down as low as it is deemed advisable without endangering the glass, and it is then gently pushed in the neck of the tube, taking care that it sets straight.

The two most important operations in the manufacture of such a tube are, however, the thinning down of the aluminum window and the sealing in of the cap. The metal of the latter

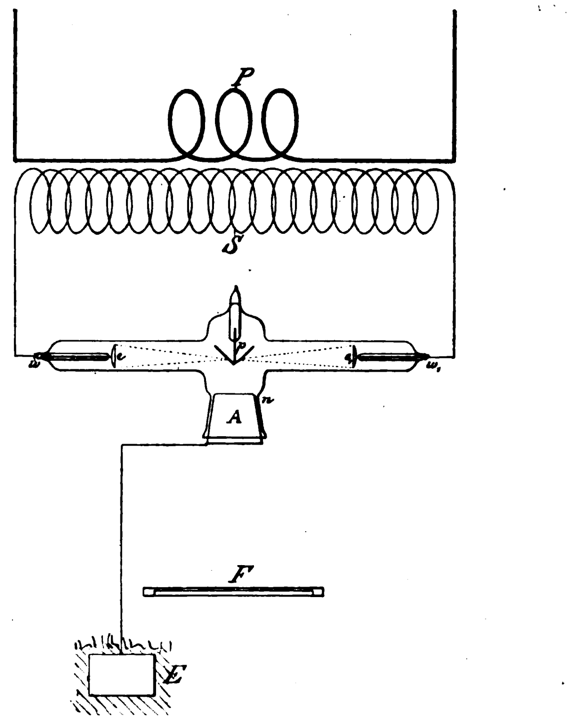

FIG. 3.

may be 1-32d or even 1-16th of an inch thick, and in such case the central portion may be thinned down by a countersink tool about ¼th of an inch in diameter as far as it is possible without tearing the sheet. The further thinning down may then be done by hand with a scraping tool; and, finally, the metal should be gently beaten down so as to surely close the pores which might permit a slow leak. Instead of proceeding in this way I have employed a cap with a hole in the center, which I have closed with a sheet of pure aluminum a few thousandths of an inch thick, riveted to the cap by means of a washer of thick metal, but the results were not quite as satisfactory.

In sealing the cap I have adopted the following procedure: The tube is fastened on the pump in the proper position and exhausted until a permanent condition is reached. The degree of exhaustion is a measure of perfection of the joint. The leak is usually considerable, but this is not so serious a defect as might be thought. Heat is now gradually applied to the tube by means of a gas stove until a temperature up to about the boiling point of sealing wax is reached. The space between the cap and the glass is then filled with sealing wax of good quality; and, when the latter begins to boil, the temperature is reduced to allow its settling in the cavity. The heat is then again increased, and this process of heating and cooling is repeated several times until the entire cavity, upon reduction of the temperature, is found to be filled uniformly with the wax, all bubbles having disappeared. A little more wax is then put on the top and the exhaustion carried on for an hour or so, according to the capacity of the pump, by application of moderate heat much below the melting point of the wax.

A tube prepared in this manner will maintain the vacuum very well, and will last indefinitely. If not used for a few months, it may gradually lose the high vacuum, but it can be quickly worked up. However, if after long use it becomes necessary to clean the tube, this is easily done by gently warming it and taking off the cap. The cleaning may be done first with acid, then with highly diluted alkali, next with distilled water, and finally with pure rectified alcohol.

These tubes, when properly prepared, give impressions much sharper and reveal much more detail than those of ordinary make. It is important for the clearness of the impressions that the electrode should be properly shaped, and that the focus should be exactly in the center of the cap or slightly inside. In fitting in the cap, the distance from the electrode should be measured as exactly as possible. It should also be remarked that the thinner the window, the sharper are the impressions, but it is not advisable to make it too thin, as it

is apt to melt in a point on turning on the current.

The above advantages are not the only ones which these tubes offer. They are also better adapted for purposes of examination by surgeons, particularly if used in the peculiar manner illustrated in diagrams, Fig. 3 and Fig. 4, which are self-explanatory. It will be seen that in each of these the cap is connected to the ground. This decidedly diminishes the injurious action and enables also to take impressions with very short exposures of a few seconds only at close range, inasmuch as, during the operation of the bulb, one can easily touch the cap without any inconvenience, owing to the ground connection. The arrangement shown in Fig. 4 is particularly advantageous with a form of single terminal, which coil is diagramatically illustrated, P being the primary and S the secondary. In this instance the high-potential terminal is connected to the electrode, while the cap is grounded. The tube may be placed in the position indicated in the drawing, under the operating table and quite close, or even in contact with the body of the patient, if the impression requires only a few seconds as, for instance, in examining parts of the members. I have taken many impressions with such tubes and have observed no injurious action, but I would advise not to expose for longer than two or three minutes at very short distances. In this respect the experimenter should bear in mind what I have stated in previous communications. At all events it is certain that, in proceeding in the manner described, additional safety is obtained and the process of taking impressions much quickened. To cool the cap, a jet of air may be used, as before stated, or else a small quantity of water may be poured in the cap each time when an impression is taken. The water only slightly impairs the action of the tube, while it maintains the window at a safe temperature. I may add that the tubes are improved by providing back of the electrode a metallic coating, C, shown in Fig. 3 and Fig. 4.

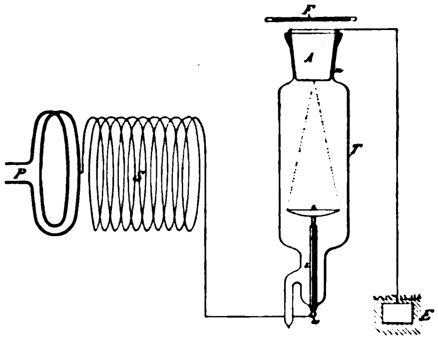

FIG. 4.

NEWS AND NOTES

ELECTRICITY AT THE BRUSSELS EXHIBITION.

(From our own Correspondent.)

THE Brussels Exhibition as a whole is quite interesting and very creditable to Belgium. Of course, it does not make any pretense of comparison with either Chicago, 1893, or Paris, 1889. No attempt has been made at lavish expenditure on building façades. The existing buildings of some royal museums, of one sort or another, have, indeed, been utilized as the façade, and it was only necessary to put up a series of sheds at the rear to make a decent and relatively inexpensive outfit of buildings. The park in which the buildings are situated forms a most artistic and beautiful foreground for the whole.

A portion of the grounds have had, of course, to be given up to various "side-shows," cafés, restaurants, etc. One of the really very interesting and beautiful side-shows is the "Panorama des Alpes." There is also a "Kermesse," which reminds one of "Old Vienna" of the Chicago Midway. It is enclosed by walls, like a fortified village, and contains an even larger number of odd Flemish and Belgian structures of all sorts and for all purposes, than did the "Old Vienna" of Austrian buildings.

Of course, the ubiquitous, loud-mouthed, vulgar oriental—he of the Midway Plaisance, is here, with his camels, donkeys, sword-dances, and "other" dances. He is not so numerous, but still is as much, yea, even more, in evidence, for he constitutes a larger percentage of the exotic element than he did at Chicago. He speaks even worse French than he did English at Chicago. He peppers and salts it freely with Flemish, which is bad enough when done by the Belgians, most of whom at least do know, occasionally, a little French. One can analyze the whole electrical part of the show in five minutes with ease and with time to spare.

The Société Gramme is, I think, the only foreign exhibitor of dynamos, except the Société Breguet, which exhibits a "Laval" steam turbine dynamo outfit rated at 150 h. p.; for it is noteworthy that almost everybody here rates dynamos by horse-power, and not by kilowatts of output, as in America. The other dynamos are exhibited by Belgian makers. The dynamos are all of the belted type, most of them small, the largest being about 75 k. w. They present no new features and recall for the most part our American "efforts" at designing belted dynamos, as evidenced at the World's Fair of 1893. Such a thing as expecting a dynamo to run sparkless from no load to full load, without change of brush lead, is still here one of the things left to the future, as it was with us in 1893, although it is now one of the usual requirements in our first class work.

There is an attempt to show long distance transmission—from Tervueren to Brussels—but even this exhibit is also a miniature. The power is transmitted a few kilometres at 4,000 volts, and furnishes a little power, such as for pumping water for the illuminated fountain.

The said fountain is rather a dismal exhibit, considering the fact that it "chews up" nearly 600 amperes, for supplying 48 arc lamps. They simply turn on the water and the current, and "let her go." Once in a while they shift the color screens. No attempt is made at varying the number, form and combination of water jets, or at giving different colors to different parts of the jets, as was so beautifully done at Chicago. Altogether the fountain is rather elementary, and about ten years behind the times.

One of the most interesting American exhibits is in the British section! It is an exhibition of electric traction materials, by Robert W. Blackwell, whom many of your readers will doubtless well remember, as the quondam manager of the Bentley-Knight Company. Mr. Blackwell is the American agent for a good deal of our best American electric traction material (line material, track material, car trucks, motors, trolley poles, etc.). He has an extensive suite of offices (comprising about the whole of one floor) in one of the finest office buildings in London, and is ably seconded by his chief assistant, Mr. Phillip Dawson, whose name is also well known in America. Both Mr. Blackwell and Mr. Dawson are members of the jury at Brussels. Their names are also identified with many electric railway lines in Great Britain and all over Europe, for which they have furnished materials, equipment, and, in many cases, have had full charge of every detail of the engineering and equipment. Their exhibit at Brussels is very complete and very interesting. It includes many ingenious trolleys, and some ornamental trolley line poles and brackets of their own design, which do them honor and might profitably be copied in America.

The grounds are illuminated by incandescent lamps entirely. The lamps are arranged in festoons, and also set in the trees, and each is covered by a globe, made of celluloid or other translucent material, colored green, red, yellow and blue. The effect is very pretty and gives the garden a fairy-like aspect, both at night and during the day.

PROF. DOLBEAR SHAKES HANDS WITH PROF. FARMER'S GHOST.

THE following story, told in a dispatch from Boston, will recall to mind the late Prof. Farmer's tendencies toward spiritualism: Prof. Dolbear has just returned from Eliot, Me., where the convention of the American Institute of Electrical Engineers was held in honor of Moses G. Farmer, one of the pioneer inventors in the field of electricity. Just half a century before to a day Mr. Farmer had operated successfully an electric car at Dover, N. H. During many years of his life Mr. Farmer lived at "Bitter Sweet," a homestead place, where he died a few years ago, and where his daughter, Miss Sarah J. Farmer, still lives. Miss Farmer entertained Prof. Dolbear, and on last Sunday the professor slept in a room somewhat noted locally as the "room of the seven doors." It is on the second floor, a small, nearly square room, that is light, airy and comfortable. Its most notable feature is its collection of

doors. The seven are all just alike, and apparently of the same size. They were finished in the natural wood, and each had a white China door knob.

"Let me tell you something about that room," said Prof. Dolbear, "or, rather, about something that happened to me there. I had been talking of Farmer with his daughter that evening, and when I turned in I was thinking of him. How long I lay there before sleeping, or whether I went to sleep at all, I do not know, but presently I was conscious of some presence in the room. A moment later I saw Farmer standing by the bed. At least I recognized the figure as that of Farmer, and I was surprised, but I do not recall that I was very much startled. 'Hello,' he said, or something of that sort—a salutation, at all events. I replied in kind, and said, 'Who are you?' 'I am Farmer,' was the answer, and he held out his hand to me.

"I shook hands with him, and I thought as I did so that the fingers felt a little cold. I released the hand and was thinking about the matter while considering what next to say. When I looked up he was gone. If I was awake at the time I fell asleep again; at any rate, I let the matter pass, though somewhat puzzled, but very soon I found the figure was again standing by the bed. I do not know that I doubted it was Farmer, but I thought I would make certain, so I said:

"'How shall I know you are Farmer?'

"'I will show you my hand,' he said. In the dark I saw he was holding out his hand that I might see it, but I was determined to take nothing for granted, so I said:

"'But how shall I know it is Farmer's hand?'

"'I'll show you my finger,' he replied, and then he crooked up one of the fingers in such a peculiar way that I tried to imitate him. I could not do it without the assistance of the other hand, and while I was trying to perform the little trick the figure disappeared. I puzzled over the vision, or dream, or what you choose, for some time, but then I once more went to sleep—if I had been awake—and I saw nothing more of the figure. In the morning I told Miss Farmer of my experience, to her very great interest. When I came to the trick of the fingers she looked at me astonished.

"'That,' she said, when illustrated as best I could, 'was a favorite little trick of my father; few people could do it.'

"It appears," Prof. Dolbear concluded, "that whenever Farmer met a person to whom he took a liking, when the acquaintance came to an informal footing, it was his way to hold out his hand, crooking his finger in the way I have shown you, to say, 'can you do that?' It was a little thing, perhaps, but peculiar to the man. We all have minor characteristics by which we may be known."

PAN-AMERICAN ELECTRICAL EXPOSITION AT NIAGARA.

IT is proposed to hold a Pan-American Electrical Exposition on Cayuga Island, Niagara Falls, in 1899. Cayuga Island is not exactly within the limits of the city of Niagara Falls, but it is not far distant, and by mentioning it in connection with the Falls its location is well defined, for who does not know of Niagara Falls? The project has been before the public through various announcements for some little time, but now the promoters of it state that their plans are maturing so that their permanent organization will be soon formed. Capt. J. M. Brinker, president of the Niagara Falls & Lewiston electric road, is at the head of the scheme, and he has interested several prominent men, among them General Superintendent Edgar Van Etten, of the New York Central, who can do much to make the project a success.

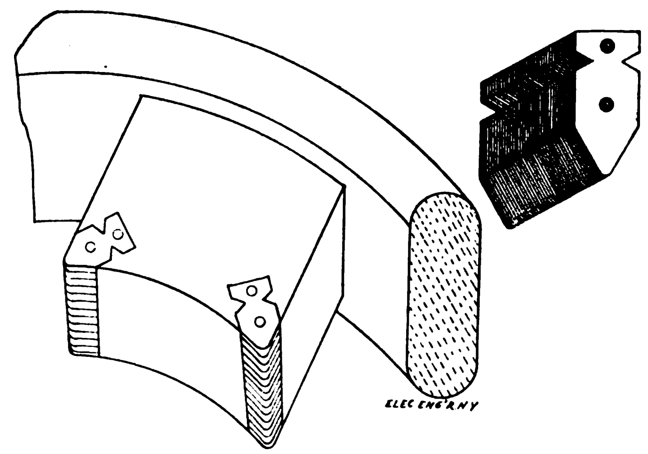
It is the idea of the promoters that the exposition shall represent and display the progress made during the last century, and especially is it designed to portray the progress made in the electrical field. So far as possible, the power and light used on the grounds will be furnished by electricity generated in the great power houses at the Falls, and in every way will the progress of the century then closing be compared with the past. It is the idea of the men who are back of the scheme that as the Falls of Niagara draw about 500,000 people to see them annually, the additional attraction of the Pan-American Exposition will swell the crowds of visitors to proportions far beyond those ever seen at any exposition in the world.

The desirability of Cayuga Island as a location for such a great exposition as is proposed will be well understood when it is stated that to-day the trains of the New York Central, the West Shore, the Michigan Central, the Lake Shore & Michigan Southern, the Lehigh Valley, the Canadian Pacific, the Wabash, the Erie, the Rome, Watertown & Ogdensburg and the Grand Trunk railroads pass within 200 feet of the island on their regular runs. Thus, the railroads of the country lead to Cayuga Island. In addition to this the cars of the Buffalo-Niagara Falls trolley line pass still closer, while, as the island is located in Niagara River a safe distance above the Falls, steamboats from the Great Lakes can land their passengers right on the exposition grounds.

RUSHMORE LAMINATED POLE CORNERS.

IN large machines with toothed armatures provision must be made to avoid heating due to eddy currents set up in the pole-pieces and with solid poles this heating is so great that it is necessary to have a large clearance which reduces the capacity of the machines and wastes copper and energy in the field coils. Most makers to-day overcome this difficulty by making the entire poles of laminated iron bunched together and cast solid into the field ring and while this method is very effective it is very costly.

It is well known that the heating of the poles is chiefly, if not entirely, at the corners or edges. In a dynamo it is in the



FIGS. 1 AND 2.—RUSHMORE LAMINATED POLE EDGES.

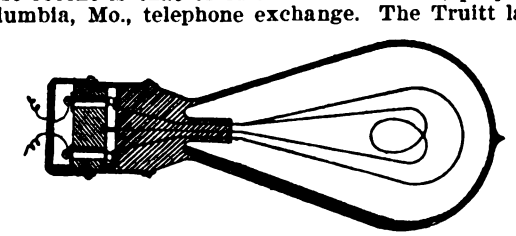
edges from which the teeth are being drawn, and in a motor the edges to which the teeth approach, and it therefore occured to Mr. S. W. Rushmore, of Jersey City, N. J., that it was necessary to laminate only the corners where the heating takes place.

Fig. 1 shows the new method with laminated sections cast into the corners of the poles. Fig. 2 shows a bunch of the iron punchings used. It will be seen that there is a great saving in labor and material over laminating the entire poles, while very few tools are required as one size punching may be used for a number of sizes of machines.

This method, which has recently been patented, is used in all the large machines built by the Rushmore Dynamo Works, of Jersey City, N. J., and it has been found fully as effective as with entire poles laminated, and the clearance may be made as small as desired.

THE TRUITT REGULATING LAMP.

NUMEROUS devices have been brought out for effecting the turning down of the light of incandescent lamps and the most recent is that of Mr. Clarence Truitt, proprietor of the Columbia, Mo., telephone exchange. The Truitt lamp, as



THE TRUITT REGULATING LAMP.

shown in the accompanying engraving, is a multiple filament lamp, with the base so arranged that any one of the filaments can be put in circuit by turning the lamp in its socket. The lamp can be run at from 2 to 24 c. p.

PATERSON, N. J.—The Edison station at Paterson was temporarily disabled at the beginning of this week by the collapse of its large coal storage bin, the loose contents of which prevented the operation of the plant.

PERSONAL

CAMPBELL SCOTT.

THIS gentleman, who has recently taken charge of the C & C Electric Company's sales in Greater New York, and of their advertising, is well known already in electrical circles. His first engagement in the field was with the old Gaynor Electric Company, of Louisville, Ky., who made the Gaynor fire alarm system, and were the Southern agents for the Sprague motors. He then took charge in the Sprague railway department and was successful in equipping several large electric systems in Southern cities. In 1890, when the Sprague Company was absorbed by the Edison General Electric Company, he became manager for the latter of their Louisville office, and then of that at Cincinnati. In 1892, prior to the foundation of the General Electric Company, he resigned and organized the Southern Engineering Company, of Louisville, which under his presidency did a very large business. In 1894, he organized the Louisville Electrical Works, and went extensively into the manufacture of transformers. He sold out of this business in 1896 to join the C & C Company as its Southern manager at Atlanta, and during the past year and a half has established it firmly and favorably through a large part of the Southern States. He has now moved on to New York at a happy juncture in the company's affairs and is applying all his energy and ripe experience to the promotion of its interests in the great fields of power current generation, transmission and application.

LORD KELVIN, accompanied by Lady Kelvin, arrived last Friday by the "Campania," and proceeded to Toronto by way of Niagara, where he took occasion to inspect closely the plant. Lord Kelvin has not visited this country for several years.

MR. GEORGE HELI GUY has an excellent article on electricity in medicine and in sanitariums, etc., appearing in the August "Chautauquan." It is admirably written and full of interesting data.

MR. O. H. FERNBACH, a graduate of Cornell, has been selected by the Japanese authorities to supervise the construction of a trolley road near Tokio.

MR. HENRY G. ISSERTEL, E. E., consulting engineer, has withdrawn from the firm of Crafts & Issertel, but will continue as sales agent for the Walker Company, with office at the northwest corner of Wall and Nassau streets, New York.

MR. JUSTUS ECK, M. A., read a very interesting paper before the International Tramways Institute of Great Britain, on the Walker system of electric traction, last April. It has now been printed in brochure form by the Walker Manufacturing Company, of Cleveland, and forms a welcome addition to railway literature.

MR. E. TREMLETT CARTER, of the editorial staff of the London "Electrician," has arrived in New York, and will attend the British Association meeting at Toronto.

SOCIETY & CLUB NOTES

A CHICAGO "BATTERY PARTY."

THE people of Chicago are now enjoying what are known as "battery parties." The Englewood & Chicago, the new storage battery road, at the present time has about twenty motor cars in successful operation over its twenty-four miles of track. The road runs through some of Chicago's most beautiful suburban districts and is becoming very popular for picnic parties and excursions. The cars run in regular service about eighteen miles an hour, and the smoothness of the roadbed removing all the jolt and jar makes a ride over the line a most pleasant experience.

On Saturday, August 17, a large portion of Chicago's electrical fraternity accepted the invitation of the Central Y. M. C. A. Electrical Club to an excursion of inspection over the road. Special battery cars were kindly furnished by Superintendent Davies, and carried the party to Blue Island and Morgan Park, stopping some time at the power house.

Much interest was shown in the ingenious appliances devised by Gen. Manager Condict for changing the batteries on the car. This arrangement, with the aid of but one operator, and in less than a minute and a half, removes the four-ton tray of discharged cells and replaces them with a charged set ready for another twenty-four-mile trip.

The model power house, with its economical appliances of condensers, cooling tower and economizer, was carefully inspected, while the steady load indicated by the ammeter dials on the switchboard created considerable comment. The system of connecting the engines and generators, which was devised by B. J. Arnold, the consulting engineer of the company, and which allows a 1,000 h. p. plant of four units to be installed in an engine room 70 feet long by 30 feet wide, and makes possible the operation of four direct connected generators from one engine, was much appreciated by the engineers of the party.

The discovery of the day, however, was made when the cars were backing out from the siding at the power house to continue the trip, when the ladies of the party, who were in charge of Mr. Sullivan, of The Electrical Engineer, were much interested in finding that "the batteries worked both ways."

The afternoon was an instructive as well as an enjoyable one and the Y. M. C. A. club added considerably to the reputation which it is making for unique entertainments.

AM. ASSOC. AD. SCI. AT DETROIT.

In accordance with the programme, the American Association for the Advancement of Science held its annual meeting at Detroit last week. There were a great many good papers, in all the departments, and some of them are noted in this issue. But the attendance as usual was very small, less than 300 having registered. For some reason or other the association does not gather the number of members that its work would appear to warrant.

This week the British Association holds its meeting at Toronto, in the University Building, and several will go thither from Detroit. The attendance from England alone is shown by the lists to be over 200, many of whom came over on the steamer "Parisian" to Montreal. Others, like Lord Kelvin, have arrived by way of New York.

OBITUARY

S. M. CANTY.

The death is announced of Stephen M. Canty, of the Southern New England Telephone Company, aged 36. He was found dead in his chair one morning last week, and his disease is said to have been heart trouble, due to cigarette smoking. He was in the company's equipment force.

TELEPHONY AND TELEGRAPHY

ENGLISH TELEGRAPHERS NOT TO STRIKE.

A special dispatch from London of August 13 says: The telegraphers connected with the Postoffice Department of the government held a great meeting this evening to discuss the question of a strike, in view of the decision of the Duke of Norfolk, the Postmaster General, with respect to the principal grievances recently laid before him by a committee of the Telegraph Clerks' Association. The Postmaster General in his reply to the petition declined to agree to an increase of the maximum salary from £160 to £190, though he promised to relieve the pressure of work by appointing forty additional superintendents and to abolish technical examinations in the case of candidates for senior grades of clerks. To-night's proceedings showed that the expected and requisite support from the Postal Telegraph clerks in the provinces is not forthcoming, and the meeting decided not to strike, but to continue to press the claims of the London association upon the government with greater resolution.

LEGAL NOTES

BROOKLYN TROLLEY DAMAGE SUITS.

Hereafter the Brooklyn Heights trolley railroad will not fight small damage claims in the court, but will settle them privately whenever possible. Fifty-four of these actions brought by parents or guardians of children who have been injured by the cars of the company have just been closed by the payment of judgments amounting to $4,132. The suits covered a period of nearly a year.

TROLLEY INJUNCTION SUSPENDED.

An order has been entered by Judges Dallas, Butler and Kirkpatrick suspending the preliminary injunction granted in the Circuit Court at Pittsburg in the suit of the Thomson-Houston Electric Company against the Johnson Company and others for alleged infringement on improvements in suspended switch and traveling contact for electric railways, under the sixth, seventh, eighth, twelfth and sixteenth claims of patent No. 495,443.

The Johnson Company, of Pennsylvania, R. T. Lane, A. J. Moxham, Claude M. Johnson, John R. Hoefgan, Daniel Coolidge, William A. Donaldson, A. V. Dupont, the Steel Motor Company, Johnson Company, of Kentucky, and the Johnson Company, of Ohio, are the appellants and the Thomson-Houston Electric Company is the appellee.

TROLLEY DECISION IN FAVOR OF THE JEFFREY MANUFACTURING COMPANY.

At Columbus, Ohio, in the case of the Thomson-Houston Electric Company against the Jeffrey Manufacturing Company, a suit on account of alleged infringement of the Van Depoele patents, Clerk White, of the United States Court, has issued the opinion of Judge Clark. In the decision he first allows a preliminary injunction upon complaint, giving bond in $15,000. After the signature attached to this the judge says that since writing the opinion he has been furnished an opinion from the Circuit Court of Appeals of the Second District, in which similar claims have been held to be invalid, these claims having been upheld by Judge Townsend, whose opinion he was following. He says: "I am now constrained to think that I would not be warranted by the rule referred to in accepting Judge Townsend's conclusion as a basis for preliminary injunction, since his opinion has been disapproved by a court of review. . . . I am of the opinion that I should not as this stage of the case allow a preliminary injunction. I think I should not do so before the October term of the court," and gives his reasons for the statement.

THE STOCK MARKET

GOOD OUTLOOK ALL AROUND.

THERE is no longer any question about the general improvement in business or the strength of the stock market. Bank clearings, railroad receipts, trade reports, high prices of agricultural products, busy times in many factories, all tell the same story, and the conditions bid fair to accentuate themselves sharply as the days go by and the fall season comes on.

On the New York stock market last week 3,480,000 shares were sold, and the sales of bonds reached $21,500,000, the largest amount in six days since 1893, comparing with only $6,500,000 in the same week last year. During the week Western Union gained 1⅜ up to 93¾ on sales of 102,489 shares. General Electric stood firm around 37 and 38 on sales of 22,880, but is inclined to be unsettled on talk of a deal as to the long unpaid dividends of two or three years' accumulation on the preferred stock. American Bell has risen to 237 on sales below 1,000 shares as usual. New York Edison has advanced 1½ to 125¼.

COPPER is firm with a rising tendency, if any, on large sales. Lake Superior is at 11 cents for September delivery; 10¾ for electrolytic, and 10⅝ for casting stock.

STEEL RAILS are quoted at $20 per ton.

REPORTS OF COMPANIES

ANGLO-AMERICAN TELEGRAPH CO.

The report of the Anglo-American Telegraph Company for the year ended June 30, states that the total receipts from January to June 30, including the balance of £369 brought forward from the last account, amounted to £166,558. The traffic receipts show an increase of £5,935, compared with same time last year. The total expenses of the half year, including the repair of cables, etc., as shown by the revenue account, amounted to £53,301, being a decrease of £3,727. The directors, under the powers conferred upon them by the articles of association, have before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £101,257. One quarterly interim dividend of 12s. 6d. per cent. on the ordinary stock and of £1 5s. per cent. on the preferred stock was paid on May 1, 1897, absorbing £43,750, and a second quarterly dividend of 14s. per cent. on the ordinary stock and £1 8s. per cent. on the preferred stock, amounting to £49,000, was paid on July 31, 1897, leaving a balance of £8,507 to be carried forward to the next account.

BROWNELL CAR CO.

The Brownell Car Company, St. Louis, has filed a deed of trust for the benefit of creditors, numbering over 100. The total amount of indebtedness is said to exceed $200,000, the deed of trust covering everything owned by the car company, including 150 feet of ground on Monroe street and fourteen other pieces of property.

TO EXPORT AMERICAN ALUMINUM.

It was announced last week that contracts had been signed for the shipment of 1,000 tons of aluminum to the English market. The order was placed in open competition with all the aluminum works of Enrope. The total American output of aluminum for 1896 was about 1,300,000 pounds, and it is estimated that the production for 1897 will reach 2,000 tons, of which, it is expected, 1,000 tons will be consumed in the United States. The delivery of the English order will cover a period of four years.

EDUCATIONAL

LEHIGH UNIVERSITY.

Lehigh University has made a well advised extension of its curriculum. The authorities of the university, being convinced that many men who desire eventually to study a technical profession would appreciate a preliminary literary education, have decided to offer such persons an opportunity of combining culture studies with those which belong to practical life. Any student in the literary courses who wishes to do so will be permitted to substitute such technical studies as are approved by the faculty, for a portion of the regular work of the junior and senior years. At the end of the four years he will receive the literary degree appropriate to his course. If he then chooses to complete the technical course to which the substituted studies belong he can do so, and may receive the technical degree in a period determined by his diligence.

AGRICULTURAL COLLEGE, MICH.

The mechanical department of the Agricultural College Mich., has arranged an elaborate series of reference cards in connection with its course of instruction. It oftens happens that young men who wish to enter a college or university have not had the preliminary training which is insisted on as a requisite for admission. It is to meet such cases as these that the Agricultural College especially offers its facilities for the study of mechanical engineering. The admission requirements, as well as the fees, are modest.

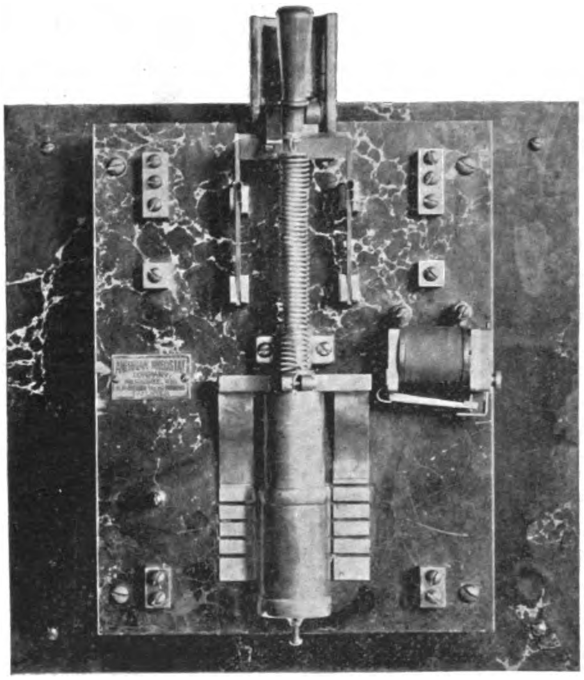
TRADE NOTES & NOVELTIES

THE PERFECTION RHEOSTAT.

IT may be considered a bold thing to call a piece of apparatus "Perfection," but the American Rheostat Company, of Milwaukee, Wis., appear to be justified in so designating their latest type of motor-starting rheostat.

This rheostat consists of a double pole knife switch, fuse block, release magnet, overload magnet and automatic circuit breaker all on one slate front. The operator closes the switch, pressing the handle somewhat, which brings a plate connected with the switch in contact with the stem of the plunger, and thereby removes the pressure from the latch. This being done, the magnet immediately draws the latch and on letting go of the handle of the switch it is retained by the latch, if there is current passing the fields; otherwise it will not catch the latch.

If the switch is retained resistance is automatically cut out of circuit. If an overload occurs the overload magnet acts, and re-



"PERFECTION" RHEOSTAT.

leases the latch, thereby opening the double pole knife switch. If from any cause the resistance is cut out of circuit when the knife switch is open, it is impossible to close the knife switch. If, on closing the switch, the current is excessive, thereby causing the overload to act, it will simply prevent the cutting out of resistance until the overload drops, when the latch will retain the knife switch, and the resistance will be automatically cut out of circuit.

With this rheostat the knife switch, fuse block, circuit breaker and accompanying switchboard and connections are all done away with.

The rheostats are built in capacities of from ⅓ to 100 h. p. and for 125, 240 and 500-volt circuits.

THE STANDARD UNDERGROUND CO. AND PAPER CABLES.

The following notice and guarantee is being issued by the Standard Underground Cable Company: "Our attention has been called to the somewhat extravagant pretensions put out by interested parties, wherein claim is made, in substance or effect, of an exclusive patented monopoly of paper insulated electric cables and wires. We have been manufacturing and selling wires and cables of that kind for many years, and under advice of counsel, we have no doubt whatever as to our right to do so. We, therefore, advise you that as regards any such wires and cables which you may purchase from us, we will be prepared at any and all times, at our own charge and expense, to defend any suit or suits brought against you for infringement of the patent referred to, we to be promptly notified of such suit or suits, and to be allowed an opportunity to make defense therein."

ACTIVITY OF THE C & C ELECTRIC CO.

It is most gratifying to hear such conservative concerns as the C & C Electric Company express their belief that the long and eagerly looked-for "good times" have at last come back in earnest, and this time to stay. One of their representatives stated a few days ago that they have received more orders, and substantial ones at that, for electrical machinery of various types and for numerous uses, during the last six weeks than they had during the previous three months. As a consequence their whole office force is "head over ears" at work, while preparations are being made to run their large shops at Garwood, N. J., both day and night with a largely increased force until they are able to catch up. Large orders have come to them during this month, not only from all over the United States, but from Central America, Japan, South America and South Africa, the latter being an evidence that the fame of C & C apparatus is worldwide.

NEW ENGLAND NOTES

FITCHBURG STEAM ENGINE COMPANY, of Fitchburg, Mass., are busy on orders. Their engines are installed in many plants throughout the country, among which can be mentioned the Mt. Morris Electric Light Company, Consolidated Gas Company, of New Jersey, at Long Branch, N. J., and notably the new shops of the Boston & Maine Railroad, at Concord, N. H., where the power is chiefly distributed by the electric motor. J. D. Miller & Co., 39 Cortlandt street, New York, are the New York selling agents.

THE ANSONIA ELECTRICAL COMPANY, Ansonia, Conn., have plenty of work on hand. They manufacture a large number of electric house goods supplies, and Shield Brand moisture-proof feeder and line wires, also annunciator magnet, damp-proof office wire, etc.

MR. G. H. ALMON, of Montpelier, Vt., has been awarded the contract for wiring the Vermont State House in that city, for $2,250. The building is to be wired throughout for 500 lamps of 24 c. p., and all wires are to be run in iron conduit.

MOSSBERG & GRANVILLE MANUFACTURING COMPANY, Providence, R. I., have just issued a very handsome new and profusely illustrated catalogue of over 200 pages. It will be promptly mailed on request to intending purchasers of power presses, drop presses, rolling mill machinery, wire drawing machinery, roller bearing gauges, roller bearer hangers for shafting, etc. These hangers are guaranteed specifically to save 50 per cent. of the power. The concern make a feature of designing and manufacturing machinery for special purposes, and will be glad to estimate on same, particularly if it is of the automatic type and intricate.

PROVIDENCE, R. I.—The American Electrical Works clambake takes place on Saturday at the Powham Club.

SOUTHERN NOTES

NEWPORT NEWS, VA.—The Newport News Shipbuilding and Dry Dock Company are making extensive additions to their already large plant. One under way is the erection of an extension to their machine shop, which will be 100 feet wide and 200 feet long. This building will be used for the finishing and erecting of marine engines and other large machinery used in connection with the mammoth steel vessels which this company have under way. The central portion of the building will be 50 feet high, and will be supplied with an electric traveling crane capable of lifting and carrying a load of 50 tons. On either side of this central space will be located a gallery arranged for small machines and fitting tools. The building is to have a steel framework throughout, and the roof is to be covered with corrugated iron. The Berlin Iron Bridge Company, of East Berlin, Conn., have the contract for furnishing and erecting the steel work of the building.

WESTERN NOTES

MICHIGAN AVENUE, CHICAGO, is now to be lighted electrically its entire length up to Thirty-ninth street, thirty-six arcs taking the place of 300 gas lamps. The circuits will be run with Standard underground cable in McRoy terra cotta conduits.

THE HIGHLAND ELECTRIC SOLDERING PASTE is meeting with a very large sale, and the Electric Appliance Company, who are pushing this specialty in the West, state that it promises fair to displace the well known soldering sticks and soldering acids, as it has many advantages over both of these two methods of making a joint. The Electric Appliance Company are still sending free samples on application.

DAVIS GLASS CO., Pittsburg, Pa., is, it is said, going to put on the market a new form of underground conduit, composed of glass, iron and asbestos. The inventor is Mr. John Locke, and Mr. Joseph Davis is the president of the new company.

WARREN, O.—A special pleasure trip was made last month to Conneaut Lake from Warren, when the entire force of the Warren Electric and Specialty Company went as guests of the concern, to the number of 150. The train was decorated and the party were under the care of Mr. E. W. Gillmer, the general manager. The excursion was greatly enjoyed.

EATON, O.—The Eaton Telephone Association is to distribute weather reports to seven stations and to about fifty farmers who have instruments.

HUGHES POLICE AND FIRE SIGNAL SYSTEM, 511 Sansome street, San Francisco, is being put on the market by Messrs. E. C. Hughes and A. C. Robbins. It includes the use of the telephone, and is said to have many improved features rendering it specially adapted to small cities and villages.

TAYLORVILLE, ILL.—The Taylorville Electric Company has an incandescent electric lighting plant and supplies steam heating by means of the system of the American District Steam Company. It has two 80 h. p. Ideal engines and two 125 h. p. tubular boilers. F. W. Anderson is president; D. D. Shumway is treasurer, and J. N. C. Shumway is secretary and manager.

MR. C. C. HASKINS, one of the oldtime telegraphers, for some years a telephone electrician, and for the past thirteen and one-half years City Inspector of Electric Lights in Chicago, having severed his connection with the municipal government, has established himself as an electrical expert, in Room 623, Western Union Building. Mr. Haskins' experience in handling electricity has been extremely varied, and extends over the greater portion of his life.

TACOMA, WASH.—The street car companies on the Pacific slope are said to be having trouble through the breaking away of many of their men for the Klondyke gold fields.

MR. CHARLES H. WILSON, formerly of the Chicago Telephone Company, has been appointed general manager of the Southern Bell Telephone and Telegraph Company.

KANSAS CITY, MO.—The president of the Northeast Electric Street Railway proposes to have the fares collected hereafter in boxes.

ST. PAUL, MINN.—The trustees of the State Insane Asylum have awarded the contract for an electric light plant to the General Electric Company for $17,200. The contract includes two dynamos, a Gates engine and wiring the hospital for 1,600 lights.

GENEVA, ILL.—The residents of Lake Geneva, Ill., are disturbed by the project of the Harvard and Lake Geneva Electric Street Railway Company, and it is said, that the authorities of the Yerkes astronomical observatory also object very decidedly on account of possible interference with the sensitive instruments employed.

ROTH BROS. & CO., Chicago, have just installed for Mr. John M. Smyth, a dry goods merchant of the West Side, a neat plant for 30 lights on board the steam yacht "Loreto," at Lake Geneva, Wis. The equipment consists of a 3 h. p. Roth bipolar slow speed dynamo driven by a Dake engine, and all the necessary paraphernalia for a complete lighting plant. The "Loreto" is 70 feet long and has engines of 150 h. p., and is one of the handsomest launches to be seen on the Western lakes.

JACKSON, MICH.—The Parrish Signal Company, to make crossings for steam and trolley roads, has been formed, with a capital stock of $100,000, the devices being those of H. H. Parrish. The president of the company is E. S. Hobbs; vice-president, C. C. Bloomfield; secretary, L. B. Trumbull; treasurer, E. D. Warner. The factory will be at Jackson.

MR. W. B. McDONALD, superintendent of the People's Light and Power Company, Chicago, has devised an arc lamp hanger board made entirely of glass, having a glass back, or support, as well as glass insulating knobs. This device, known as the McDonald Glass Hanger Board, can always be relied upon as a perfect insulator, and always looks bright and clean. This specialty is being placed on the market by the Electric Appliance Company, Chicago, who will be very glad to quote prices on application.

FORT WAYNE ELECTRIC CORPORATION will, according to current rumors, build electric street railway apparatus.

PHILADELPHIA NOTES

EPHRATA, PA.—The borough council has awarded the contract for lighting the streets with twenty 3,000 c. p. long burning arc lamps, to run until midnight, at $65 a year, to F. E. Bailey, of Philadelphia. A company has been organized and a site secured for the location of the plant, and work will be commenced at once. The plant will have a capacity of thirty arc lights and 1,000 incandescents.

ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, have closed a contract with the National Electric Car Lighting Company to furnish them with storage batteries, and will at once equip fifty cars at Atchison, Kan.

KEYSTONE ELECTRIC COMPANY, of Erie, Pa., F. B. Downing, president, write us that they have closed a contract recently with the McAdams & Cartwright Elevator Company, of New York, for eleven 20 h. p. and three 5 h. p. electric elevator outfits. These will be installed in a large new Broadway building.

"THE PLUNGER," a submarine boat on the lines of the "Holland," recently described in The Electrical Engineer, has just been launched for the Government from the works of the Columbian Iron Works, Baltimore. She can dive 20 feet in 10 seconds.

PULLEN BATTERY AND ELECTRIC MANUFACTURING COMPANY, of Camden, N. J., has been formed, to make reversible primary batteries and other apparatus. The capital stock is $100,000. The incorporators are L. W. and J. M. Pullen, of Camden, and C. L. Klander and A. E. Bainbridge, of Philadelphia.

EARLY TELEGRAPHY.—The Philadelphia, Reading and Pottsville Telegraph Company has just celebrated the fiftieth anniversary of the sending of the first message over its lines. It was chartered March 15, 1847, and it claims to be the oldest telegraph line in the United States.

HAGERSTOWN, MD.—It is said that the men on the Hagerstown Electric Road are kicking not because of overwork, but because they have to wear high collars all the time, summer as well as winter.

NEW YORK NOTES

NEW YORK CITY. The Metropolitan Traction Company has bought the branch of the Union Railway Company's system, running by trolley on One Hundred and Thirty-fifth street to Madison avenue bridge, and it will convert it into a conduit system, connecting with the Lenox avenue conduit road and giving rapid transit all over the west side for one fare of five cents.

SHEEHAN & HEWITT, electrical engineers and contractors No. 40 South Water street, Newburg, N. Y., will hereafter act as selling agents for the C. & C. Electric Company through the central, northern and western counties of New York State.

BROOKLYN, N. Y.—A fatal accident occurred at Ridgewood Park on Sunday, August 1, when F. McDonald, riding his illuminated bicycle on a tight rope charged from the trolley circuits, fell 75 feet to the ground and was killed. His sensational act was described in The Engineer some time ago, and it is remarkable he should have gone on so long without accident. It is said his foot slipped from one of the pedals.

SARATOGA, N. Y.—The Saratoga Gas, Electric Light and Power Company are rebuilding and rearranging their gas plant, and have let the contract for the steel work connected with the generator house roof and the roof over their cold storage building to the Berlin Iron Bridge Company, of East Berlin, Conn. The roofs have steel trusses covered with corrugated iron.

DOLGEVILLE, N. Y.—The Electric Light and Power Company have contracted through G. W. Pulver & Co., Syracuse, N. Y., with the Westinghouse Electric and Manufacturing

Company for two 450 k. w. two-phase alternating current generators, one 250 k. w. rotary transformer, exciters and a large marble switchboard, together with a number of transformers for lighting and motor work. The generators will be connected to Victor turbines running at 300 revolutions per minute under 72 feet head. The rotary transformer will deliver direct current at 600 volts for the present direct current motor service in use in various manufacturing establishments. The alternating current generators are of 7,200 alternations.

EASTERN ENGINEERING COMPANY, of New York City, has been formed to carry on a general mechanical and electrical engineering business, with a capital stock of $5,000. The directors are F. E. Tyng, Elizabeth, N. J.; F. R. Haines and S. T. Tyng, New York City.

JOHN WENNSTROM COMPANY, Forty-first street, Brooklyn, N. Y., manufacturers of jewel bearings, report their factory busy on some good orders.

SCHMINKE & NEWMAN, 325-27 Baroune street, New Orleans, have secured the contract for the electrical work for the new St. Charles Hotel annex, in that city. The new iron-armored conduit manufactured by the Interior Conduit and Insulation Company, of New York, will be used throughout the work.

NEWARK, N. J.—That was an excellent suggestion of Superintendent Reilly, of the New York and New Jersey Telephone Company, in reference to the color of the poles. The Common Council had a clause in its ordinance requiring all the telephone poles to be painted white above 8 feet from the ground. This would make them about as conspicuous as possible, while Mr. Reilly suggested that dark green or olive would be far better. The sensible nature of the suggestion commends it to all.

PALMYRA, N. Y.—The Palmyra Electric Light and Power Company are extending their system and are in the market for wire, street lighting fixtures and general material. They say that there is an opening in the vicinity for an electric road.

NEWARK, N. Y.—At the recent outing of the Consolidated Traction Company's employés at Bergen Point, Conductor Mike Carroll was accompanied by his valet, E. Blanchard, who carried a dress suit case for him.

ELECTRIC HEADLIGHTS are reported to have the advantage not only of illuminating the track far ahead, but of disturbing by the brilliancy of their beam any animal that may be sleeping or lying down on the track; thus preventing collision or derailment.

POSTAL TELEGRAPH COMPANY has laid complaint before the State Railroad Commissioners, against the Mobile & Ohio road, in Tennessee, for discrimination in distributing Western Union poles but refusing to handle any for the Postal Company.

NEWBURG, N. Y.—The Consolidated Gas, Electric Light, Heat and Power Company is going to put in the Holly system of exhaust steam heating. Pipes will be laid in a large number of streets. The system is that of the American District Steam Company, of Lockport, N. Y.

THE NATIONAL TELAUTOGRAPH COMPANY is pushing the Gray invention again with improved and perfected mechanism. Gen. T. M. Logan is president of the company, and J. W. Johnston, general manager.

JAMAICA, W. I.—The West India Electric Company, Ltd., is being formed at Kingston, Jamaica, with a capital of $1,-250,000 to operate electric tramways. Those interested are S. C. Burke, L. Verley, R. J. Macpherson, P. E. Auvray, S. L. Schloss, W. Andrews and A. R. Saunders, who are connected with the present mule street railway.

MR. LAFOREST TRUE, of Clinton, Fairfield, Me., has bought machinery for the equipment of a plant for the manufacture of electrical supplies. He is now beginning operations.

ELECTRICITY IN JAPAN.

A correspondent of an electrical manufacturing concern writes from Tokio, Japan, saying: "Since October last a number of electric light companies have been started here. Several mines are endeavoring to get their power transmitted distances of from five to seven miles, using 2,000 to 3,000 volts, and utilizing water power. The Hiroshima Water Power Company is going to buy at first three 250 k. w. tri-phase generators, with step-up and step-down transformers. The Hiroshima plant will be the first Japanese long distance power transmission scheme involving a 10,000-volt circuit. The Japanese government for some time past has been busily engaged in extending telephone exchanges and in starting long distance telephones. Solid back transmitters, multiple switchboards and telephone cables are required, and the American manufacturers, it is thought here, could meet British competition."

AHLM-EDWARDS PLANTS.

The following is a list of recent orders received by the Ahlm-Edwards Electric Company, of Cleveland, Ohio:

One 17½ k. w., 125 volt, 825 r. p. m, generator for Chase & Sanborn, Chicago; one 7½ h. p., 500 volt, 1,400 r. p. m. elevator motor and one 15 h. p., 500 volt, 1,200 r. p. m. elevator motor for Edmonds Elevator Company, Cleveland, O.; one 5 h. p., 220 volt, 1,000 r. p. m. elevator motor for the Enterprise Printing Company, Cleveland, O.; one 3 h. p., 220 volt, 1,100 r. p. m. motor for W. Plotz, Cleveland, O.; one 42 k. w., 250 volt, 850 r. p. m. generator for the Enterprise Boiler Company, Youngstown, O.; one 7½ h. p., 220 volt, 700 r. p. m. elevator motor for the Britton Printing Company, Cleveland, O.; two 1 h. p., 220 volt, 1,300 r. p. m. motors and one 2 h. p., 220 volt 1,200 r. p. m. motors and two 3 h. p., 220 volt, 1,100 r. p. m. motors for the A. S. Gilman Printing Company, Cleveland, O.; two 1 h. p., 220 volt, 1,300 r. p. m. motors and two 2 h. p., 220 volt, 1,200 r. p. m. motors for the Britton Printing Company, Cleveland, O.

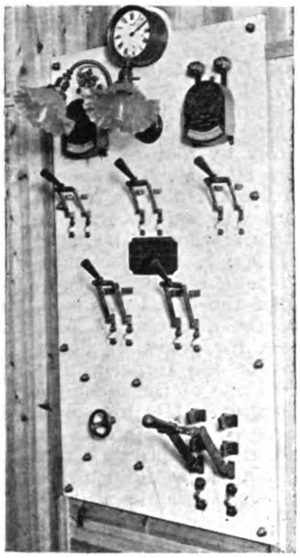
ELECTRIC LIGHTING

AN INTERESTING ISOLATED PLANT AT YOKOHAMA, JAPAN.

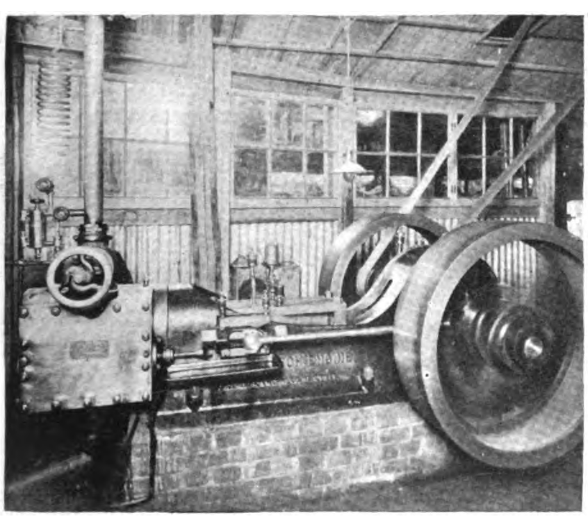
BY LAMAR LYNDON.



Japan-Made Switchboard.

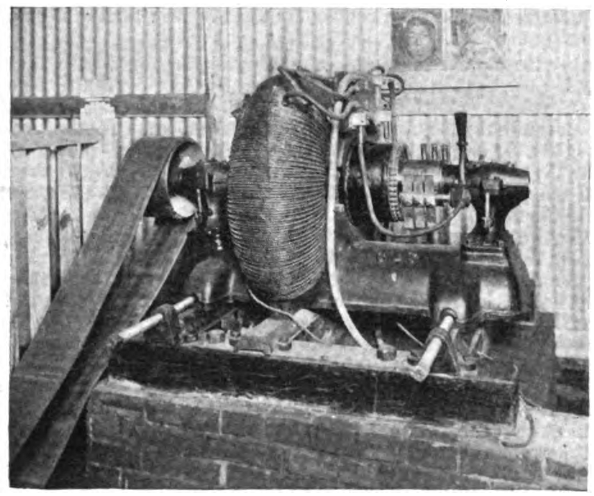
THE following description of a small isolated lighting plant recently installed in Yokohama may be of interest, because of the fact that it is, so far as the writer can ascertain, the only private plant ever installed for the purpose of lighting the same class of establishment, i. e., a tea firing "Godown."

As is well known, the principal product exported from Japan and China is tea, and at most of the ports of these empires there are large eseablishments for the "firing" or "curing" of this leaf. This raw tea is put through several processes of cleaning, sifting and assorting, with the aid of homely, native-made machines, which consist essentially of an arrangement of sieves agitated in any of usual mechanical methods, with fan-blowing attachments. The tea is then carried to the firing room, which is equipped with rows of iron pots, about 26 inches in diameter, set in brickwork, underneath which a slow fire is kept going. A coolie, either male or female, attends each pot, stirring the tea continuously, so that it is thoroughly roasted. An idea of the extent of this industry may be gained, when it is stated that a reasonably large tea firing godown, contains about 1,500 of these pots, and that they are kept going night and day during the shipping season. One of the largest companies in Japan, engaged in this business, is the firm of Messrs. Averill



ISOLATED GENERATING PLANT IN A YOKOHAMA TEA FACTORY.

& Co., of Yokohama. They employ over 2,000 people in the busy season, and their firing rooms, warehouses and sifter rooms are quite extensive. Up to the beginning of the present season, they have obtained their current from the local electric company, and their bills were discouragingly large. Moreover the steam engine they were then using to drive the sifting machinery was a most extravagant steam consumer. It was an old 10-inch by 16-inch slide valve engine made in Tokyo several years ago, and running 60 revolutions per minute, or 160 feet piston speed, which necessitated plenty of steam, and a corresponding amount of coal, to get any power out of it. This combined expense of coal and light was so considerable that the Messrs. Averill finally called in the writer to make such changes and additions to the steam plant as were deemed necessary, and to install in conjunction therewith, a complete electric plant. Accordingly, a contract was entered into with the American Trading Company, of Yokohama, this company agreeing to import and install the necessary equipment and guarantee the satisfactory operation of same. The boiler then in use, which was made in England and is of the Lancashire type, being in an excellent condition, it was decided to retain it. The old engine was torn out, and in its place was installed one of the modern high speed en-



ISOLATED GENERATING PLANT IN A YOKOHAMA TEA FACTORY.

gines, built by the Phoenix Iron Works Company, of Meadville, Pa. The size is 8 inches by 10 inches, and it runs at 350 revolutions per minute. It is equipped with a "Rites" governor, which is extremely sensitive. It is impossible to observe any speed variation with change of load, though a chronograph would probably indicate a slight fluctuation.

Many years ago, the spot on which Yokohama now stands, was a marsh, which was gradually filled up as the settlement increased in size. Consequently it is some trouble to get a good foundation in many parts of the city, and so it was in this case. However, it was not practicable to drive piles, and so the next best thing was resorted to, namely the excessive spreading of the foundations as they went down, thus making up in area what they lacked in solidity of bearing. This was done in the case of both the engine and the dynamo foundations. They were built of brick, laid with a mixture of best Portland cement and sand, in the proportion of 2½ parts of sand to 1 of cement. The piping from the boiler to the engine is of best extra heavy 2½-inch pipe, having all joints flanged, and all bends made of lengths of the same, bent to proper curvature. Just over the engine is a 2½-inch vertical Cochrane steam separator, which delivers absolutely dry steam to the steam chest. The exhaust pipe, which is 3 inches in diameter, rises to a height of 10 feet, and enters a feed-water heater of the closed type. This heater was made by a Yokohama firm—Peterson & Co.—and consists of a shell having inside top and bottom plates, into which are fastened by screw ferrules, 100 copper tubes ⅞ inch in diameter. The exhaust passes through the tubes, and the feed-water around them. A top and bottom blow-off relieves the feed-water of scum and sediment, and the water enters the boiler at about 210 degs. F., and practically free from scale-forming material. A drip in the bottom of the heater clears it of all condensed steam. This heater is hung from the roof truss by four ⅞ inch rods that pass through proper plates in the roof and through lugs bolted to the bottom of the heater. Water from the city waterworks is used, passing through a Cameron boiler feed-

pump, by means of which it is forced through the heater into the boiler. All the piping, even down to the ½-inch steam pipe to the feed-pump, is extra heavy and connected with flanged couplings and long bends. All drips are piped together and run into a common drain pipe leading to the sewer. It was not considered desirable to further complicate this small plant by any steam traps or drip return systems.

Some trouble was experienced in piping the pump and engine, owing to the fact that all pipe threads in these machines were, of course, cut to the American standard, while all the tools in use in the shops in Japan are English standard. In some cases new flanges were made and in others the pipe ends were cut on a lathe to fit the American threads.

The dynamo is of the medium speed bipolar type, made by the C. & C. Electric Company, of New York. It is of 16 k. w. rated capacity at 125 volts, and is compounded for a 4 per cent. rise on full load. It is equipped with the usual ring oilers and spherical socket journals, and has operated perfectly without any hitch or trouble from the day it was started. It is mounted on a heavy brick foundation that rises 15 inches above the pavement of the engine room. On top of this are the base frame and sliding rails, which raise the machine 5 inches more, making the bottom of the dynamo 20 inches above the floor line. This was considered desirable on account of the tea dust, that settles down and floats about close to the floors. This tea dust is very penetrating and manages to get into the engine room, though it is tightly closed by wooden partitions.

The switchboard is made of a single slab of white marble, 2½ by 5 feet. On it are mounted three 30-ampere and two 50-ampere feeder switches and one 150-ampere main dynamo switch, made by Eyanson & Armpriester, of Philadelphia; a C & C back connected rheostat and an ampere meter made by the Western Electric Company, a double lamp bracket, which was made in Tokyo, and a copper encased clock, which was of Swiss manufacture. The board was made by the Japan Marble Company from sketches made by the writer, and for their first attempt is a very creditable piece of work. All connections are made in the back, and none of the wiring is visible from the front of the board. The slab is mounted on an angle iron framework, being fastened thereto by eight ⅜-inch steel studs, having an ordinary nut and washer on the back and with a thick beveled washer and cap nut of copper in front. The studs holding the rheostat to the board are furnished with washers and nuts of the same kind, which give a handsome finish to the board. In order that the slab might have an even bearing surface against the framework, strips of rubber ¼ inch thick, and the width of the angle bar, 2½ inches, running the entire length of the board, were interposed between it and the iron. There are two vertical angle bars forming the frame, to which the slab is bolted, one on each side. At their lower ends they are bent back at right angles to the vertical, and extended back about 30 inches and bolted to an iron plate, 36 inches by 30 inches, this plate, of course, being in a horizontal plane. A foundation was built, covered with cement, and the plate set on it. Then the brickwork was continued upward to the level of the engine room floor, leaving the plate firmly imbedded. This method of placing in position is permanent, secure and independent of any alterations in the walls or partitions of the building.

The connections from the dynamo to switchboard consist of two lead-covered cables of approximately the same area as No. 000 B & S, from the dynamo terminals to the main switch, and two No. 12 B & S rubber-covered and braided wires from the field coil terminals to the rheostat. These are carried in a small underground conduit of brick and cement, the small wires being separated from each other and from the cables by insulating knobs strung over them at intervals. After the conductors were placed in the conduit, it was filled with melted rosin, which entered every crevice, and hardening, formed a perfect insulator and protection from moisture.

The connection with the city lighting company's mains was retained, a breakdown switch being installed at the meter, and not on the switchboard, as is usually customary. The peculiar and Japanesque arrangement of the interior wiring made this advisable.

Some trouble was experienced at first in getting the Japanese engineer in charge to operate the plant properly. The old engine had run at the deliberate pace of 60 revolutions per minute, and 350 was too speedy for his mind to grasp. Consequently, he throttled the engine down to about 200, at which speed the governor is inoperative, and the dynamo cannot be brought up to voltage. It was some time before he could be induced to open the throttle fully, and then he did it with a sort of an "I-know-what-will-happen-but-if-you-insist-on-being-a-fool-you-take-the-responsibility" air, and I think he was really surprised that the whole thing didn't fly to pieces. However, as soon as he saw that it went all right at the proper speed and was taught how to bring the voltmeter pointer to the right position by turning the rheostat handle, he immediately developed into an electrical engineer of deep and profound wisdom and resource, and was quite willing to furnish any desired information to the contracting and installing engineers, and would, no doubt, have so favored the builders of the machinery had they been accessible. However, this "breed" is well known in the United States, and the vexatious side of the question there is that the majority of people know so little about such matters that they cannot see through the bluff and pretentions of these "sogenannten" engineers, who usually are possessed of about sufficient information and intelligence to engineer the motive power of a one-horse plow. However, there are many good, practical and well informed engineers in Japan, and they are doing excellent work.

In this connection I may mention the fact that the matter of distribution of power in mills and factories is being taken up with considerable interest. Some of this work has been done in a desultory way in one or two of the government arsenals.

To the Nippon Shario Kabashika Kaisha (anglice, "Japan Railway Car Building Company"), of Nagoya, however, belongs the honor of first placing a complete plant of this kind in which all the power of the engine is converted into electrical energy, and distributed entirely by motors. The entire equipment is of C & C apparatus, an 80 k. w. slow speed multipolar generator, and a number of bipolar motors being used. A battery of chloride accumulators will supply light to the offices at night. The selection of this method of transmission is due to the persistent efforts of Mr. I. Hattori, the chief engineer of this company, who has long recognized the superiority of electrical transmission over the usual methods, and has labored unceasingly to induce the directors of his company to adopt it. Mr. Hattori was, for years, in charge of some of the most important shops of the Imperial Government Railways, and is recognized as one of the most learned and progressive engineers in the empire. His approval will undoubtedly do much to advance electrical interests in this field in Japan, and it is to be hoped that American apparatus will hold its own in the Far East, notwithstanding the strenuous efforts of the English, Swiss and Germans to supplant it with their own products.

LIGHTING THE NIAGARA UNIVERSITY WITH ACETYLENE GAS.

BY ORRIN E. DUNLAP.

It is probable that the largest buildings in the United States, if not in the world, now lighted throughout by the new illuminant, acetylene gas, are those of the Niagara University and Seminary of Our Lady of Angels, at Niagara Falls. This well known educational institution is located on the bank of the Niagara River, just beyond the northern boundary of Niagara Falls, and being in a somewhat isolated spot, so far as the modern facilities of cities are concerned, it has for years maintained its own gas plant. This plant was of the crude oil variety. The college buildings are very large, and from October to April about 2,000 feet of gas is consumed every night. The crude oil gas was found satisfactory, and had been in use since 1870, but, owing to various circumstances, a change was deemed advisable. With this object in view, Rev. Father Hayden was authorized to install any system of light he felt would be satisfactory. Father Hayden had been impressed with the value of acetylene, and in order to get more knowledge of its efficiency as an illuminant he visited Philadelphia. A trip to Philadelphia increased his confidence in acetylene, and on his return home he made contracts for the installation of a plant for the college. This contract was made with the F. W. Oliver Company, of Ni-

NIAGARA UNIVERSITY, LIT BY ACETYLENE.

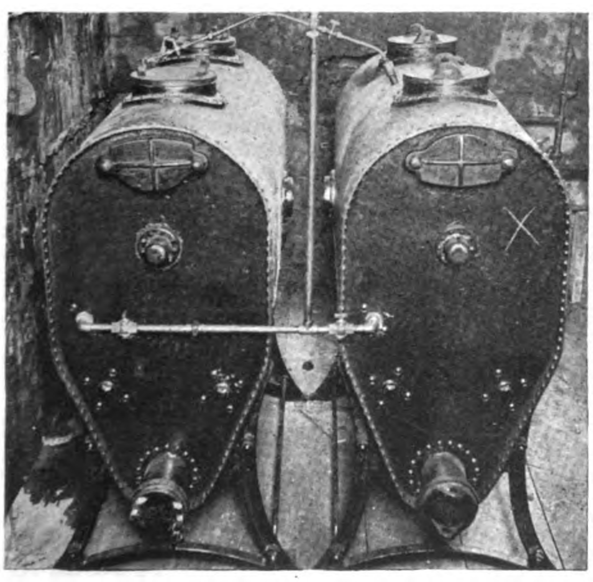
agara Falls, and the plant was installed under the supervision of William Erskine.

On the college grounds, standing about 100 feet from the main buildings, there is a stone building known as the gas house, and it is in this building that the acetylene generators are placed. They are two in number, of the Dolan pattern and automatic in their workings. A ½-inch pipe runs from the gas house to the college buildings, and it is through

Gas House, Niagara University.

this pipe that the supply passes. The buildings were already piped for gas and changes were necessary only in the style of burners. The burners in use are of the half-foot variety. Of these there are 197 in the main building, 34 in the chapel, 12 in the printing office, 40 in the postoffice building, and 4 in the engine room, or 287 in all. Under the crude oil system of lighting they, heretofore, had 32 lights in the study room, but these have been replaced by eight acetylene lights, on which shades have been found necessary owing to the brilliancy.

The college was founded in 1856. The attendance of students each year is very large. It stands among the leading colleges of the country, and the adoption of acetylene has attracted no little attention. The carbide being manufactured at Niagara Falls by the Acetylene Light, Heat and Power Company, the supply is very convenient. Before the door of the gas house are to be seen two of the drums in which the carbide is packed, each drum holding about 1,100 pounds. Heretofore it was necessary to employ a man for making



Two Acetylene Gas Generators, Niagara University.

gas, but under the acetylene system installed, the only requirement is that somebody shall visit the gas house once a day and turn the wheel that agitates the carbide in the generator, so that gas will be generated. It is calculated that the cost of maintaining the acetylene plant will be about one-third of the cost of the crude oil plant. The new installation has been in service a short time, and has given highly satisfactory results. It will not be surprising to hear of other large isolated buildings in Western New York adopting the system. Much interest has been displayed in the Niagara University plant, and people from quite a distance have made it a point to see it. Almost every night the college has visitors to see the new light, but the courtesy of the reverend fathers is unfailing.

EDUCATIONAL

THE COURSES IN ALTERNATING CURRENTS AT THE UNIVERSITY OF WISCONSIN.

BY PROF. DUGALD C. JACKSON.

TWELVE years ago a half-dozen young men graduated from electrical courses in the engineering schools of the country. There were then but two such courses—one at Cornell University and one at the Massachusetts Institute of Technology—and these had been founded almost simultaneously during the college year 1882-83. The first graduates from each course left college in June, 1885; four from one college and two from the other. It was some years before the initiative of these colleges was followed by others, but we now find the electrical engineering course generally given a position in the engineering schools, which is equivalent to that held by the courses in civil engineering, mechanical engineering and mining engineering, and there are no less than a dozen engineering colleges at which a dozen or more students graduate each year from the electrical engineering course.

The early formal courses in electrical engineering differed very materially from those of the present time, and the differences may be largely traced to the differences in the extent and complexity of the profession as practiced then and now. The early courses made much of telegraphy and telephony; not too much, indeed, but very much in contrast to the attention then given in the courses to the heavier applications of electricity, such as electric lighting, transmission of power and railways. Several divisions which now constitute highly important parts of the curricula in electrical engineering were entirely wanting in the early courses. No fixed instruction on the theory of the magnetic circuit and the magnetic properties of iron, with appilcations to the dynamo, for instance, was introduced for some time after 1885. In fact, our present views of the magnetic circuit may justly be said to have become generally diffused only during the present decade. Neither were courses in alternating currents or applied electrochemistry found in the early curricula. The latter, even now, does not receive the attention that it deserves, but the former has come to hold an indispensable place in all thorough college courses in electrical engineering.

The early development in the applications of alternating currents was brought about through the most arduous experimenting, while little or no safe theory based on the underlying or fundamental facts of the phenomena involved had been developed in a manner which might enable it to serve as a guide to the extending of known results, or the obtaining of new ones. The essentials were doubtless all to be found expounded within the covers of Maxwell's "Magazine of Electrical Facts and Theories," and probably elsewhere, but the application of these expositions was not readily perceived, and, in fact, is often quite obscure. A decade of experiment of the part of constructors and of study on the part of theorists has now given us a sound foundation of accumulated facts upon which to erect satisfactory theories which may be directly applied to problems relating to alternating current phenomena and to the construction and operation of alternating current machinery.

The use of alternating currents in commercial ventures is so extended that an adequate course in the theory and practice in alternating currents and the construction of alternating current machinery and plants is an essential part of all reasonably complete college courses in electrical engineering; while the knowledge which is now had of the subject makes it possible for satisfactory instruction to be presented.

The question of text-books on this subject has been a matter of much difficulty in the past, but there are now several books of a more or less satisfactory nature which deal with the general subject or its various ramifications, between which a choice may be made. The most important class room course in alternating currents at the University of Wisconsin comes in the regular senior year of the electrical engineering students and follows Jackson's "Alternating Currents and Alternating Current Machinery." This book, in fact, puts in type the alternating current instruction which has been presented

at Wisconsin for several years past. The complete instruction in alternating currents at Wisconsin includes a course which is more advanced than that given to the seniors, and which is presented to graduate and special students who have satisfactorily passed through the senior work or its equivalent.

A text-book which appeals to me as eminently fitted for this advanced course has lately appeared in Steinmetz's "Alternating-Current Phenomena." I have tried various books as the text in this work, including Thomson's "Polyphase Electric Currents," "Courants Polyphasés," by Rodet et Busquet, and "Courants Alternatifs Industriels," by Loppé et Bouquet, and have been forced to abandon them all as entirely inadequate for the purpose. Steinmetz's book, however, seems to be well planned for the purpose. The only reasonably available book on the subject besides Steinmetz's, which I have not tried, in this advanced class, is Kraemer's "Der Drehstrom," and that lies under the disadvantage of being printed in the German language—a disadvantage which is insuperable in the case of the class composed of mixed college graduates.

The fact that calculus is supposed to be excluded from Steinmetz's book has led some to believe that it should make a satisfactory first text-book in the subject of alternating currents for the electrical course. Such an idea takes entirely too much for granted, however, and it appears to me as unavoidable that any class of college students who enter upon the subject with the assistance of this book will obtain, as a whole, a remarkably foggy and distorted idea of the subject of alternating currents; unless, perchance, the teacher adds by way of explanation, illustration, and design so much material that the labor becomes equivalent to that of writing his own text-book. On the other hand, as said above, the advanced student with a good knowledge of alternating currents can use this book with much advantage.

"Alternating Currents," by Bedell and Crehore, which is used as a first text-book in the subject in some colleges, has given me no satisfaction whatever. Its study does not place before the student's mind any idea of the engineering features of alternating currents, though it doubtless does give him training in mathematics and experience in resolving differential equations; but the latter appears to me to be the matter of least importance in the study of alternating currents. Mathematical skill is convenient, but a real physical conception of the phenomena dealt with is the essential to be sought after first, last and all the time, and all other considerations must be subsidiary. With Jackson's book as the first text-book and Steinmetz's book as an advanced text, students can be brought with considerable ease to what appears to be a good physical knowledge of the phenomena of alternating currents and their applications, including the construction and operation of alternating-current machinery and plants. No other texts have given what seemed to be reasonably satisfactory results in my classes.

I hope that the distinguished authors of these various books, each of which has many admirable points, will not take umbrage at my frank statement of experience.

In connection with the text-book instruction, we give, at the University of Wisconsin, a thorough elementary course of laboratory instruction in alternating current measurements and the testing of alternating current machinery, which holds in the alternating current course a place which is similar to the place of the laboratory course in either of the other important branches of electrical engineering. This laboratory work has three objects in view: 1. To illustrate and reinforce the class room instruction and give the student a vivid physical conception of alternating current phenomena, which it cannot be hoped that he will get from class room instruction alone. 2. To give the student a working idea of the magnitudes of impedances, inductances (self and mutual), capacities, etc., which are to be met with in actual machines and circuits. 3. To illustrate the methods of operating alternating current machinery and show the way to make complete tests on the same, with instruction in the use of the special instruments which may be conveniently used.

The fixed list of experiments used in the alternating current laboratory contains about seventy-five numbers, varying from those which are very simple to those which are quite complex. In the course of regular undergraduate work no student has enough time to assign to this work to enable him to accomplish more than half the experimental work represented by the list; but the assignments of experiments among fixed groups of students are attempted to be made so as to give to each individual in the group a representative series, while the entire group, the members of which work to a certain degree in consultation, covers the ground of the whole list to a fair conclusion. Special emphasis, however, is laid in the undergraduate course on the first sixty numbers of the list.

To set forth the entire list of experiments in this article is scarcely desirable, but the following examples will illustrate the list. The numbers given show the numerical order of the experiments in the laboratory list and the page references refer to Jackson's text-book.

1. Measure impedance of inductance coil when connected to 50-volt and 100-volt circuits (frequencies of 125 and 60), using amperemeter and voltmeter. Measure resistance. Plot vector diagrams and determine values of reactance and inductance. Pps. 90 and 161.

2. Measure impedance, using amperemeter and voltmeter, of coil of low inductance and coil of high inductance in series, when connected to 50-volt and 100-volt circuits (frequencies of 125 and 60), at the same taking readings of the pressure across the terminals of each coil individually. Plot vector diagrams and get values of total reactance; resolve into constituent triangles and determine values of individual reactances of each coil. Pps. 90 and other.

4. Measure impedance of condenser when connected to 50-volt and 100-volt circuits, using amperemeter and voltmeter (frequencies of 125 and 60). Determine value of capacity, assuming power absorbed to be negligible. Pps. 81 and 165.

5. Measure impedance of inductance coil and condenser in series on 50-volt and 100-volt circuits (frequencies of 125 and 60). Plot diagrams and determine reactances. P. 171.

(The apparatus issued to students for use in the preceding and similar experiments must, of course, be properly chosen, so that, for instance, the opposing effects of inductance and capacity will be plainly evidenced.)

7. Determine exact value of self-inductance of a long solenoid, for use as a standard: (a) Calculate from windings and measured dimensions. P. 42. (b) Measure by method of Maxwell and Rayleigh. P. 93. (c) Measure by method 3a, using variable inductance box. P. 98. (d) Measure by method 4a, using Marshall divided microfarad as a standard. P. 103. Scrutinize the results and compare the accuracy and convenience of the methods.

9. Determine curve showing variation of self-inductance of transformer secondary with saturation of core. Use method 4b for inductance measurements and magnetize the core by passing a continuous current through the primary coil. P. 104.

10. Measure self-inductances of armature and fields of continuous current dynamo with fields unexcited, using method 3a or 4b. Pps. 104. Repeat measurements of armature self-inductance when fields are fully excited. Pps. 104.

11. Measure self-inductance of alternator armature in various angular positions by methods 1 and 3a, the fields being unexcited. Pps. 90 and 104.

12. Repeat, with fields fully excited.

13. Measure working self-inductance of alternator armature when carrying full load current and with fields excited to full value, three-fourths value, one-half value by method 1. P. 90.

15. Measure self-inductance of alternating current voltmeter and calculate the effect of frequency on its indications. Use method 2a. Pps. 93 and 16.

16. Calibrate the same voltmeter and experimentally determine the effect of frequency upon its indications.

18. Calibrate an indicating wattmeter and experimentally determine the effect of frequency on its indications when used with a non-inductive load.

19. Measure self-inductance of pressure coil of wattmeter used in 18, calculate correction factor for non-inductive load, and compare with the results of 18.

21. Determine external characteristic of alternator with non-inductive load. P. 272.

22. Repeat, using inductive load.

23. Repeat, using a capacity load (increase effect of condensers, if necessary, by means of a step-up transformer).

25. Determine form of alternator pressure curve by ballistic method and deduce magnetization curve. P. 289.

32. Determine form of pressure curve of city lighting circuit, using synchronous motor to drive contact maker.

36. Determine form of current curve in series field of composite alternator.

37. Bring two alternators to equal pressure and synchronism, then connect them in parallel. Alter the belt speed of one machine, a known small amount by means of the friction cone pulley, from which it is driven and measure the synchronizing current. Repeat the operation until the synchronizing current becomes equal to the full load current for the machines. Plot results so as to show the relation between the difference of the driving speeds of the machines and the synchronizing current. Pps. 329 and 341.

38. Synchronize and connect in parallel two alternators of equal pressure, and determine the effect on the synchronizing current of decreasing the field excitation of one. Pps. 329 and 362.

39. Synchronize and connect in parallel two alternators of

equal pressure and throw the belt off one. Determine the load (as a motor) at which the free machine breaks from synchronism.

40. Repeat with an inductance coil in the armature circuit of the free machine.

(It is desirable to use alternators of from 3 to 10 kilowatts' capacity for the experiments on alternators, or one such alternator may be used in connection with a fixed current supply from a large machine. Either arrangement is used at the University of Wisconsin as convenience dictates.

44. Measure mutual inductance of transformer coils: (a) By method 1. P. 407. (b) By method 2. P. 408. (c) By method 3a. P. 411. (d) Calculate self-inductance of each coil, assuming magnetic leakage to be negligible.

46. Determine forms of curves of primary and secondary currents and pressures and their angular relations in a transformer with no load and with full load, using contact maker and electrostatic voltmeter.

47. Determine regulation curve (P. 490), curve showing variation of magnetic leakage with load (P. 496), and curve showing variation of power factor with load (P. 497) for a transformer.

48. Measure iron losses in transformer core by the three voltmeter method and compare with wattmeter measurements. P. 125.

51. Efficiency test of transformer by Sumpner's method (method 8a): (a) Measure iron loss by wattmeter, correcting to standard pressure. P. 485. (b) Measure copper loss by wattmeter, correcting for residual iron loss. P. 486. (c) Calculate quarter, half, three-quarter and full load efficiencies. Plot curve. P. 485. (d) Calculate all-day efficiency on basis of five hours full load and 19 hours no load. P. 492.

52. Measure efficiency of fully loaded transformer on non-reactive circuit using wattmeter in primary circuit and amperemeter and voltmeter in secondary circuit. P. 382.

53. Measure losses due to hysteresis and Foucault currents in transformer core, using wattmeter, and separate them. P. 500.

55. Determine hysteresis constant of iron sample by means of Ewing hysteresis tester.

56. Measure loss due to dielectric hysteresis in condenser and calculate the effect of this loss on condenser current and apparent capacity.

59. Determine curve showing relation of armature current to excitation of synchronous single-phase motor, and find excitation for maximum power factor. Pps. 580 and 582.

60. Determine efficiency curve of synchronous single-phase motor by wattmeter and prony brake.

62. Determine efficiency curve of polyphase induction motor by wattmeter and brake measurements. Pps. 560 and 653.

64. Determine power factor curve of polyphase induction motor from no load to full load. P. 654.

67. Determine efficiency, power factor, and transformation ratio of rotary transformer.

69. Measure efficiency and ratio of transformation of experimental transformer for transforming from three to two phases.

70. Measure phase angles on primary and secondary sides of transformer for phase transformation.

71. Determine forms and relative positions of pressure waves on the two-phase and three-phase sides of phase transformer.

The list illustrates the progressive nature of the laboratory instruction. The student's level of view is first lifted out of the plain of Ohm's fundamental law into the mountains of its generalization, and after he has gained a true understanding of the significance of the simpler phenomena of the alternating current circuit he goes progressively into the experimental study of the alternator, transformer and motor of the single-phase circuit and finally the more complex machinery of polyphase types. The latter experiments cannot be fully covered during the time which it is possible to allot in the undergraduate course, even to this important subject, especially as the proper solidarity of treatment demands that much emphasis shall be laid on the earlier experiments relating to measurements in alternating current circuits, testing of alternators, testing of transformers, paralleling of alternators and the action of synchronous motors. It is hence necessary to leave the greater part of the laboratory work relating to polyphase machinery till a graduate year. A certain amount of the latter can, indeed, be done in the undergraduate course, but this must be all of the most elementary character, such as making simple measurements of power in polyphase circuits of different character, testing rotary transformers, phase transformers, etc. There is each year at Wisconsin a class of graduate students who have completed the first year's work, and who go ahead in the laboratory to the completion of the fixed list and often beyond.

The favorite subjects of study by graduate students in electrical engineering at Wisconsin have been alternating currents, theory of electricity and magnetism and applied electrochemistry, in about the order given; these subjects being under the direction of different teachers in the department.

Study in another direction—design—is, like work in the laboratory, necessary to a proper appreciation and understanding of alternating current machinery. Electrical engineering students in college should, of course, receive thorough instruction in draughting, kinematics and machine design; but special instruction is necessary to adapt the general to the special. So that draughting room designing of generators, transformers and motors is not only desirable, but essential. Computations relating to the design of alternating-current generators, with the exception of certain peculiar features, follow so closely the methods used in continuous current computations that special instruction in alternator design does not seem necessary except so far as relates to controlling the form of pressure wave, armature reactions and armature self-inductance—features which, at the best, are rather obscure. An allotment of time for the complete design of alternators therefore, appears to be unnecessary provided the alternating current instruction has been preceded (as is essential in a satisfactory course in electrical engineering) by a thorough and satisfactory course in electromagnetism and the design and construction of dynamos.

The design of transformers is in a different category, and the Wisconsin undergraduate students are all required to make at least one complete design of an alternating current transformer, following the very complete physical theories of the transformer presented in Jackson's "Alternating Currents," with dimensions checked by means of the empirical data presented therein (which was compiled from a large mass of constructive data of transformers of many makers), and also by comparison with the original data of numerous transformers, which is put in shape for use in the draughting room. The design of polyphase transformers and induction motors conjoins with the graduate course in alternating currents and is carried on therewith. It is entirely impossible to get it into the undergraduate course with the entrance requirements as they now stand in nearly all of our engineering schools.

There is much engineering matter bearing upon the use of alternating currents which does not relate directly either to alternating current theory or alternating current machinery, but does relate to the transmission and distribution of electricity. So much of this may be treated in common with the transmission and distribution of continuous currents that it seems best to include the work with the instruction in electric lighting, electric transmission of power, and central station management, rather than to burden the alternating current instruction with matter which must be given general treatment in any event when dealt with under the above divisions. By this means duplication of instruction is avoided and the most advantageous use is made of all of the student's time. The arrangement thus set forth makes it necessary that instruction in electric lighting, electric transmission of power and central station management shall be contemporaneous or consequent to the instruction in alternating currents and not antecedent thereto, but this is the natural and logical order and would probably be chosen in any event.

A COURSE OF STUDY IN ELECTRICAL ENGINEERING.[1]

BY PROF. R. B. OWENS, UNIVERSITY OF NEBRASKA.

MY object in presenting the following paper is to call attention to the difficulty with which instruction in electrical engineering is kept abreast of the current development of the subject, and to point out certain expedients found useful, in this connection, in a school distant from the larger industrial centers, and in maintaining a sustained interest on the part of the student and fitting him more quickly for the responsibilities of engineering work.

The unparalleled growth of electrical industries in the past decade and their present increasing rate of development makes the task of bringing the school work to correspond to best engineering practice. seem an almost hopeless one. But unless such a correspondence does obtain, an injustice is done the student, at least if he is allowed to believe that the work he is doing is strictly professional work similar to the work done in the best schools of law and medicine.

To be sure it is contended by some that it is only within the province of the school to impart the broader principles that underlie engineering in general and its several branches in

[1]Read before the Society for the Promotion of Engineering Education.

particular, but a careful study of the possibilities of technical training very clearly shows that much of the time now spent by the student in learning to apply general principles might be saved if in the last year or two of study he is brought into closer relation with the methods and practice of our more successful makers and best constructing engineers.

I do not wish to be understood as saying that all the details of dynamo manufacture, street railway construction, etc., can even be touched upon in a course in electrical engineering. Such details vary so rapidly as to make it impossible for a school to follow them, even if it were advisable. However, it is generally known, outside of the schools, that little information of real value relating, for instance, to dynamo design, not electric and magnetic theory on the behavior of particular dynamo machines, is obtainable in the greater number of courses in electrical engineering in this country. Such a condition when looked at fairly is readily explained. The men who to-day are successful designers of dynamo machinery and builders of electric lighting and railroad properties that pay, are so constrained by business relations as not to be able to conduct college work and college men when summer comes take refuge as a rule in the country rather than in a shop or factory, and so begin their autumn work with small additions to a usually scant fund of practical information.

However, the electrical manufacturer and lighting and street railway managers are generally glad to assist the schools, as many who have received courtesies at their hands can testify, and if close relations between the school and practice do not obtain it is the fault of the college man. In short, the college man should work as hard during his so-called vacations in collecting material for the coming season's lectures as he does during the scheduled period for conducting classes. The instructor in electrical engineering has, of course, the newness of his subject as a special difficulty to contend with, but if the practice is followed of visiting every year the plants of the manufacturing companies, typical lighting and power stations, etc., information is obtained which cannot at present be found in engineering literature, and which has the highest value for instructional purposes. In engaging an instructor in technology it should be with the understanding that cultivating close relations between college work and outside practice is a part of his duty and a limited consulting practice when not conducted to the injury of the practicing engineer should be encouraged.

I have adopted the following practice in teaching dynamo design: First, the student is drilled in the theory of electromagnetism and the magnetic circuit and is then required to fill out in detail the same data sheets that are used by our best manufacturing firms, for a number of machines of which working drawings are available. I find this especially useful in giving the student an idea of the porportions which do obtain or have obtained between the parts of single machines. Next curves and tables are made, showing the variations in the principal proportions of machines of different types and sizes. This gives the student an idea of the change in particular proportions with conditions of service and output. Necessarily the data possessed by a technical school is not of the latest, but supplementing it by the information secured each summer, a very close approximation to correct practice is obtained.

Having worked over all the material available, the present tendencies in dynamo design are pointed out as well as can be and explanations given. Then a line of machines for certain assumed conditions is decided upon and each student takes one machine. The work after this is largely at the drawing board. The advantage of having all students working on machines of the same type, but of different dimensions is, that by comparing notes they are able to see clearly the necessary change in dimensions as the output, etc., of the machines varies.

A line of standard D. C. and A. C. machines are always required, and special machines, if time allows. All drawings are made uniform and complete data sheets filled out for each machine. Next the data and drawings are submitted for criticism to some one whose business it is to design machines to maintain the reputation of and earn an income for those who invest their money in the manufacture of electrical machinery. In this way it is attempted to give the student salable information without sacrificing principles to unnecessary detail.

Lectures on electrical lighting, street railways and general installation work are supplemented by a required design of a lighting or railway plant. A number of scale drawings of towns of various sizes are available and from known or assumed conditions the station is located. Then, if it is a lighting plant, the location of individual consumers is assumed with particular load diagrams for each. From the individual load diagrams the nature of the station load is determined and the machinery and circuits laid out. All circuits are calculated and shown on the map together with poles and important accessories. Setting plans for standard machinery are readily obtainable and the station arranged accordingly. This is, of course, the ordinary preliminary survey of the consulting engineer. Next, full specifications for the plant are drawn definite as regards results to be obtained but impartial as regards standard apparatus. Well drawn sets of similar specifications are, of course, available to the student and criticised for his benefit.

Lastly, a bill of material is made and costs are worked out for some one type of standard machinery from price lists and labor estimates, and the cost of operation and maintenance and necessary income determined to make the plant a paying investment. Such station plans and estimates are then checked by a constructing engineer, whose routine work keeps him directly in touch with such matters.

The tendency to carry system to an extreme in some engineering laboratories is greatly to the student's disadvantage. If on entering a laboratory a student is met with a long list of inconsequent experiments, handed a batch of laboratory forms and told to begin observations with apparatus already set up by a laboratory assistant, his interest in research takes rather a sudden fall. Having explained the use of instruments, the general methods of dynamo testing and the peculiarities of particular machines, better results are obtained by turning over to a group of students a dynamo with necessary testing apparatus and letting them work out results as far as possible unaided. Care must be taken, however, to point out the tests that have a commercial value.

After having equipped a dynamo laboratory with machines of standard type to furnish current in necessary quantity and at convenient voltage I believe the remaining space should be filled with what in effect are simple testing blocks. Then as new machines come upon the market they can be borrowed, tested and returned, giving new apparatus for investigation without finally making a junk shop of the laboratory.

I believe very thoroughly in the value of a thesis requirement for undergraduate technical work. It is not expected that such theses will develop new principles in engineering as some seem to expect, but very much valuable data as to the various types of new apparatus continually coming out is obtained, and the student learns to assume responsibility by being in a large measure left to his own resources.

Another expedient of utmost importance in bringing schools of electrical engineering into close contact with current development is that of having specialists in the several fields of practical work give courses of lectures detailing the status and probable development of their work. One lecture by a distinguished engineer, while it interests for an evening, does not meet the requirement. I find courses of about ten lectures to cover satisfactorily such special topics as the design and construction of power plants, electric measuring instruments, etc. On these courses of lectures the student should be examined as upon work given by the ordinary instructors. So long as instruction in electrical and other special branches of engineering cannot in general be preceded by longer courses of preliminary training due to the pressing demands for technical information made by the recent enormous growth of our industrial interests, the granting of a full engineering degree for the ordinary four years of college work seems unwarranted. The recent graduate is not an engineer; we only hope he has the capacity to become one. A safer course, and one which I have adopted in granting the degree of Electrical Engineer, is to require certain additional or graduate work after the bachelor's degree, and the full degree is conferred at any subsequent time when the applicant presents a dissertation showing that he has actually planned and carried out electrical work of some importance. If such a practice were general, I believe the degree would secure more attention than it does at present. A continued effort should also be made to raise the entrance requirements to engineering courses. This will finally be effective I think in bringing the special branches of engineering into our graduate schools along with other strictly professional work.

A LIST of saloons and messenger companies which have wire connection with houses of ill repute has been forwarded to the St. Louis City Lighting Department, and a gang of men will take down the wires. The list was prepared by the police, in response to a request made by the City Lighting Department. A city ordinance says that no such telephonic communication shall exist, and it is proposed to enforce the law. It is shown in this report that the Cable Messenger Company has forty-six signal boxes in houses of this class, while the Eureka Messenger Company has thirty, and the Western Union Telegraph Company has forty-one boxes.

MISCELLANEOUS

ROTARY TRANSFORMERS.—III.

BY C. F. SCOTT.

(Concluded.)

SUMMARY of Characteristics of a Rotary.—A rotary acts both as an alternating current motor and as a direct current generator and has the following characteristics:

(1) The machine is similar to an ordinary synchronous motor in its dependence upon the wave form and the e. m. f. of the circuit to which it is connected and upon the speed of the generator. A circuit which is variable in speed or in e. m. f. may produce an unstable condition in a rotary, which tends to produce a mechanical oscillation or "pumping" action. This may be so slight as to cause no practical inconvenience, or it may be sufficient to cause periodic sparking of an injurious amount or a fluctuation in the e. m. f. delivered, or it may be so great as to prevent the mechanical running of the machine.

(2) Rotaries are of two types, the direct current field rotary and the induction rotary. The former type requires a much more careful adaptation to the circuit on which it is to be operated, and is much more sensitive and liable to disturbance in its operation than the induction rotary, although its successful operation in service proves that there is no question as to its commercial success. The induction rotary is a simpler and cheaper machine to construct and to operate; it possesses many advantages over the first type and can in general meet all conditions more successfully, except those requiring considerable compounding, especially with variable loads, and for operation of large sizes on high alternation circuits.

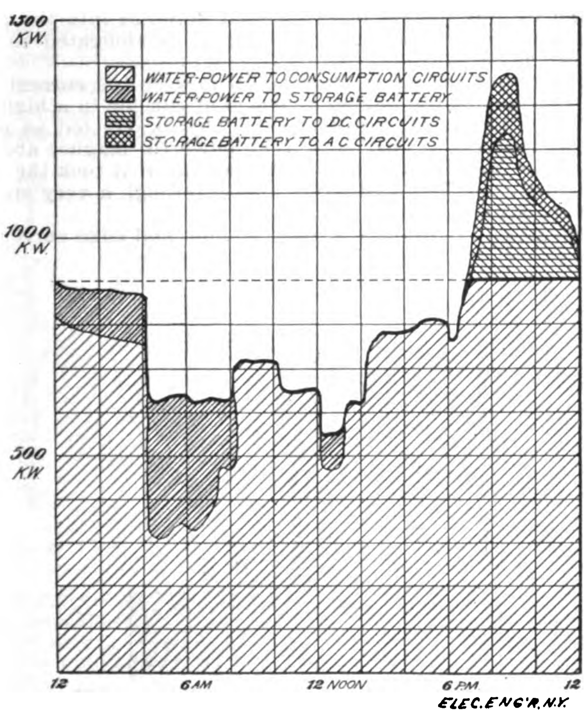


FIG. 13.—LOAD DIAGRAM AT HARTFORD.

(3) With the same output the loss in the armature conductors of a rotary is less than it is in a direct current machine; therefore, if the loss be kept the same the output of a machine of given size can be increased. In a three-phase rotary the output can be increased about 30 per cent. and in a two-phase rotary about 60 per cent. over the output as a direct current machine, the loss being the same and the efficiency consequently increased.

(4) The current in the armature of a rotary is distributed in such a way that there is little current in the conductors in front of the pole faces, thus avoiding the distortion of the field magnetism, which is common in direct current machines. This enables the machine to commutate a larger current and renders it less sensitive to changes in lead of the brushes. It also reduces the loss in the armature iron.

(5) The e. m. f. delivered by a rotary may be varied over a wide range by adjusting the alternating e. m. f. delivered to it, and it may be varied to a slight extent through proper compounding of the field or setting of the brushes.

(6) The e. m. f. for which a rotary can be constructed depends upon its frequency and the greater the number of poles required for a given speed. On a 3,000 alternation circuit a machine will run at 700 revolutions if it has four poles, while on a 7,200 alternation circuit there must be ten poles for a speed of 720 revolutions. The brushes on one machine rest on the commutator at four points, dividing it into quadrants, while on the other machine they divide it into ten parts, so that if the commutators be of the same diameter the distance between brushes is much less in the high alternation machine. The number of commutator bars and consequently the e. m. f. which can be commutated is also less.

As the size of the commutator is limited by the peripheral speed, it is evident that the greater the number of poles the less is the e. m. f. for which a machine can be built. If the number of alternations remains the same, it is not possible to increase the number of commutator bars by changing the number of poles. For if the number of poles be made half as great then the number of brush holders is correspondingly reduced, but the diameter of the commutator must also be reduced in the same proportion in order to maintain the same peripheral speed. This makes the distance between neutral points on the commutator the same with the fewer poles.

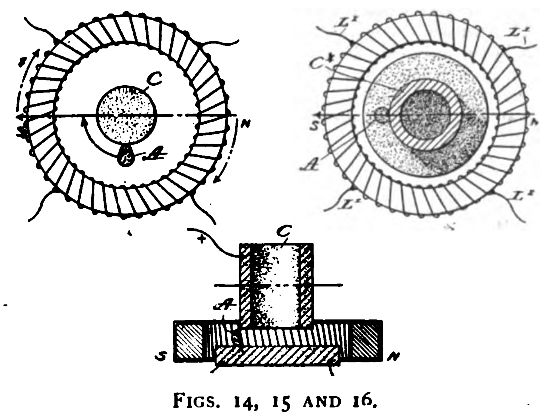
The author then refers briefly to the employment of rotaries at Hartford, Niagara and Buffalo, showing the great flexibility obtainable by their employment. Fig. 13 is a curve showing the load diagram at Hartford, where rotaries charge storage batteries. The latter have enabled a maximum load of nearly 1,500 k. w. to be handled by a water-power of 900 k. w.

ELECTRIC FURNACES.—III.

BY LIEUT. F. J. PATTEN.

(Concluded.)

FIG. 13, page 180, shows in cross-sectional elevation a furnace constructed on plan of using a continuous current between electrodes and an alternating field. The lower electrode, C^2, is given a slanting position, so that material between electrodes will slide, or flow down, its surface from right to left, while the arcs between the several upper electrodes and the lower one are traversing back and forth from one side of the magnetic field, N S, to the other, thus maintaining practically a sheet of electric flame, through which the material must pass.



FIGS. 14, 15 AND 16.

The rotary or revolving arc systems are illustrated in Figs. 14 to 18, inclusive. The principle used is plainly indicated in Fig. 14, in which C represents the horizontal projection of the lower carbon electrode and A is the arc. The arcing space is surrounded by an iron ring, in which a rotating magnetic field is set up by introduction of multiphase alternating currents to its continuous Gramme winding. The interior of the ring is, therefore, a magnetic field, which is continuously revolving in the plane of the ring and consequently the arc, A, in its endeavor to keep out of the magnetic field is rapidly revolved around the carbon electrode.

Various are the methods of applying this principle; two will

be briefly described. In one, Figs. 15 and 16, a hollow tubular carbon, C, is used for an upper electrode and a flat disc or slab for the lower one. The upper tubular carbon can be availed of as a feeding pipe to supply the material to be treated to the arc, which latter, owing to the moving magnetic

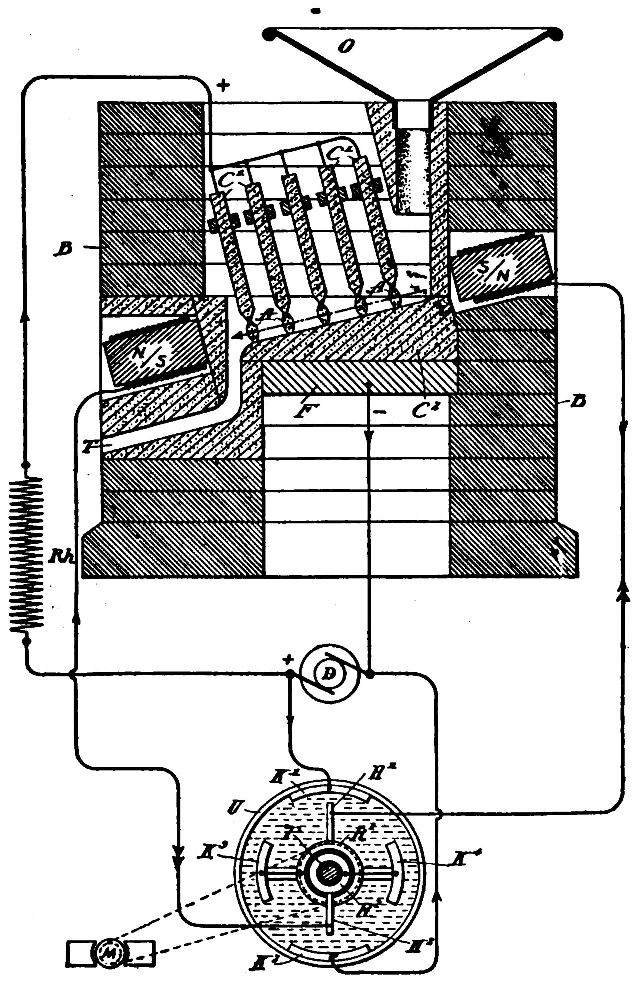


FIG. 13.

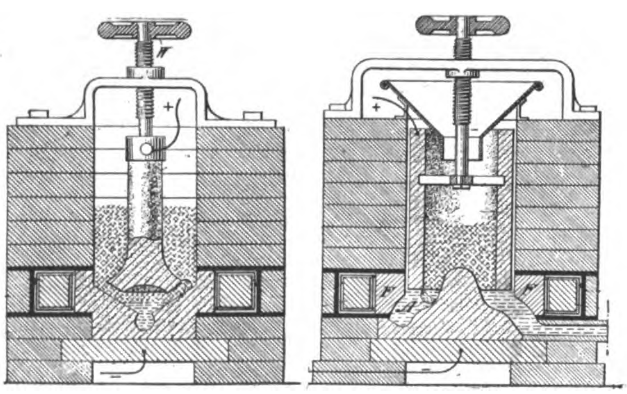
field in which it is placed, continuously revolves around the lower edge of the upper carbon tube or pipe.

Figs. 17 and 18 show furnaces built on these principles, one having a solid carbon electrode and a carbon furnace floor for the lower electrode, and the other a tubular upper electrode serving also as a feeding pipe for the furnace and a carbon floor piece for bottom electrode as before. In both Figs. 17



FIGS. 17 AND 18.

and 18, illustrating these furnaces, the magnetic ring surrounding the arc space is shown in section at N S.

It only remains to describe the rotating current, or revolving current incandescent system, as it might properly be styled, presenting as it does a means of causing the working current after having fused the carbon pencil of the ordinary incandescent system, before referred to (Fig. 7), to revolve, an axis of revolution remaining always on the outer surface of the molten or fused mass. In this way it is made to continually attack new material just outside the surface of the nugget already formed, and which compared with the lime and coke mixture is a good conductor.

The chief defect in the incandescent or pencil system lies in the fact that after the carbon pencil is fused and a nugget or pencil of carbide has been formed in its place, this prism of carbide in the fused state is a fairly good conductor, much

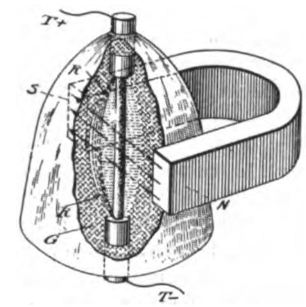


FIG. 19.

better, in fact, than the surrounding mixture. The result is, the current rushes through this sort of short circuit and is wasted, doing, of course, little or no work after it has once fused the mixture to carbide. At this stage of the operation the carbons are drawn further apart, so as to increase the resistance by introducing more unfused material into the path of the current. In this way the nugget is elongated to the limit of the furnace.

In the rotary current system I aim to keep the current out on the surface of the nugget or pencil of carbide in a high resistance path of unfused mixture. This is effected as indicated in Fig. 19, by placing a very powerful magnet around the path of the current, so that the current, if it took the normal or direct path, would have to pass through a very strong magnetic field.

In Fig. 19, G represents a mass of lime and coke surround-

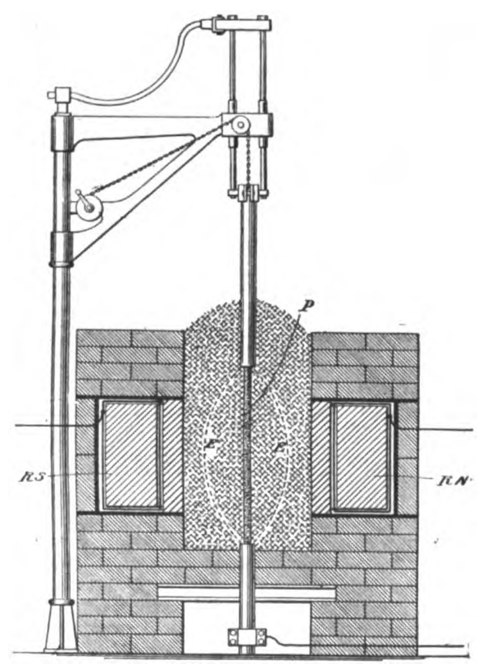

FIG. 20.

ing the carbon pencil and N S is a magnet, the poles of which surround it. When the pencil has been fused the current will then take the curved path between electrodes indicated by R, R, instead of passing in a direct line from one electrode to another, as it would do under normal conditions. Of course, in practice permanent magnets are not employed, but a magnetic ring is used as in the rotary arc furnace.

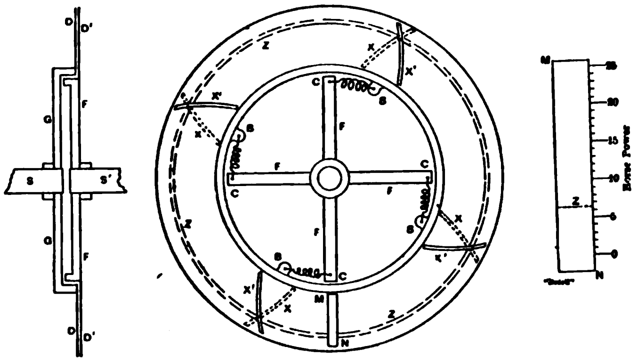
A vertical section of such a furnace is shown in Fig. 20. The magnetic ring, R N, R S, is shown in section, its intense magnetic field surrounds the working current or pencil or

prism of carbide, as it may happen to be, from one step to another of the operation. The ring is excited by multiphase alternating currents of very low periodicity, so that there will be a powerful and slowly revolving magnetic field through which the working current will be passing at right angles. This will cause the current to abandon the direct path across from carbon to carbon and to take a curved path as indicated by the dotted lines in the figure. But as the field is slowly revolving the current, like the arc, in its endeavor to get out of the magnetic field, will also revolve, describing an ellipsoid of revolution on the outer surface of the molten mass. In fact, it should go out as far as there is a conducting path for it. In this way it is designed to keep the current at work on new material continuously and build the nugget out laterally as well as longitudinally. It is almost obvious that if this plan is practicable on a very large scale, it will add greatly to the economy of the incandescent method.

THE BEDELL TRANSMISSION DYNAMOMETER.

AT the recent meeting of the American Society of Mechanical Engineers, Prof. R. H. Thurston described a transmission dynamometer designed by Dr. Frederick Bedell, which has been used for some years in a different form in experiments upon synchronous motors. The instrument has given such satisfaction that the application of the principle to the transmission dynamometer is advocated.

The dynamometer is shown in Figs. 1 and 2, which have been drawn to show the relation of the parts rather than the



FIGS. 1, 2 AND 3.—BEDELL TRANSMISSION DYNAMOMETER.

actual construction of the instrument. The shafts, S and S′, are the two shafts between which the power is transmitted; these are arranged in line and with ends abutting. The shafts are connected by any convenient system of springs; this system may consist of a single spring or a number of springs, which may be either for tension, torsion or compression. The annular disc, D, supported by the frame, G, is carried by the shaft, S. A similar disc, D′, supported by the frame or spider, F, is carried by the shaft, S′. In the particular form shown, the frame, G, carries four lugs, B, which are connected to the spider, F, by the springs, BC, which may be either springs for tension or compression.

Let us suppose that we have the shafts, S and S′ running, let us say, at a constant speed and with a variable load; that is, the shaft, S, is transmitting an unknown and varying amount of power to the shaft, S′. When the shafts are idle they have a certain angular position with relation to each other. When they transmit power, however, the shafts depart from the zero position with reference to each other by an angle which depends upon the strength of the springs and the torque between the two shafts.

In the disc, D, are slits, X, X, X, X; corresponding slits, X′, X′, X′, X′, are in the disc, D′. These slits are slightly curved, as shown in Fig. 2, the exact curvature necessary being explained later. The slits in one of the discs are the exact counterpart of the slits in the other disc, curving, however, in the opposite direction. The slits thus superposed give a single point of intersection. As the shaft, S′, is turned through a given angle with reference to the shaft, S, the slits, X, shift with reference to the slits, X, and the point of intersection of the two slits is accordingly moved inward or outward from the center of the discs. The openings formed by the intersections of the slits will show a continuous ring of light, Z, if the discs are illuminated from behind. For a constant torque the position of this ring of light will remain constant. The ring of light will, however, move inward or outward as the torque varies.

The slits are made of such a curvature that the change in the radius of the circle of light, Z, is directly proportional to the change in the angle—that is, to the torque.

The instrument may be direct reading, and experience has shown the following form to be convenient. An incandescent lamp is placed behind the discs. This lamp is enclosed in a suitable opaque box so that it illuminates only the disc. In front of the discs is a stationary opaque screen covering entirely the whole apparatus. In this screen is a ground-glass window, MN (see Fig. 2). The incandescent lamp is behind the two discs and directly opposite this window. Instead of a complete circle of light, Z, we only see a line of light across this window.

The scale at the side of this window shows the horse-power direct for a given speed, as shown in Fig. 3. As explained above, the slits are made of such a curvature that the divisions of the scale in Fig. 3 are equal. The position of the line, Z, in Fig. 3 indicates 6.3 h. p. at a speed, let us say, of 400 revolutions per minute. When the speed is not maintained constant, it is necessary to determine the speed and to correct the reading accordingly.

TESTING PICTURES BY THE ROENTGEN RAYS.

A correspondent of the London "Elect. Rev." says: In the possession of Herr Friedrich Burger, of Munich, is a fine old painting of the Saviour crowned with thorns, which has been generally ascribed to Albrecht Dürer, though some critics had expressed themselves as doubtful on this point. In 1893 the Grand Duke of Baden had discovered after a long and careful search the monogram of Dürer, and determined the date 1521. As this discovery did not satisfy all the sceptics, the owner of the painting conceived the novel plan of submitting the painting to the action of the Röntgen rays. After many unsuccessful attempts, success was at last attained. The magical picture produced by the Röntgen rays excited the greatest interest and astonishment. The picture of the thorn-crowned Christ was exactly reproduced with correct light and shade, also the cross nimbus surrounding the head and marked above with the initials A and D. Moreover a signature was discovered in late Gothic characters, and Dürer's monogram with the date 1521 as had already been made out by the Grand Duke of Baden. The picture was painted on silk stretched on an oaken board 2 cm. thick, covered with interlaced oak fibres, and these are all shown distinctly in the Röntgen image. This application of the Röntgen rays may prove of considerable value to picture dealers and others in detecting fraudulent imitations of valuable paintings.

THE ROENTGEN RAYS AND CARDIAC AFFECTIONS.

Before the Congress on internal diseases, at Berlin, Germany, Prof. Benedict, of Vienna, stated that the most important result of the employment of the X-rays in this department of medical science had been the ascertainment of the strength and extent of the heart's movements in healthy and unhealthy conditions. They had shown that the work performed by a sound heart had been greatly over-estimated, and they had thus rendered the vibrations of a diseased heart easier to understand. Doctors were now in a position to learn the size and position of the vital organ in cases where the former methods of ausculation and percussion had afforded them no help. By the Röntgen rays it was possible to observe deterioration of the valves at a much earlier stage than previously, and to gain exact information as to the relations between the heart and the diaphragm, as well as to observe the movements of the membrane. In the early diagnosis of disease of the lungs, stomach, and kidneys, the rays rendered doctors important assistance; and it would in future be possible to gain a knowledge of diseases at a stage at which they had previously entirely escaped detection.

VOL. XXIV NEW YORK, AUGUST 26, 1897. No. 486.

THE FIRE ALARM TELEGRAPH.

THE past record of the fire alarm telegraph in this country might well be termed ancient electrical history, yet the highly important part which it plays to-day in conserving life and property well entitles it to a reminiscent glance, and this has been given in the admirably concise historical paper read by Mr. Adam Bosch before the American Institute of Electrical Engineers at their recent meeting at Eliot, Me. Mr. Bosch's contribution was particularly apropos to the occasion and place, as to no one more than to Moses G. Farmer was due the ultimate successful establishment of the fire alarm telegraph system. As early as 1845 Dr. W. F. Channing had publicly advocated the establishment of such a system in Boston and had, indeed, with wonderful prescience, laid down its general principles. Yet it required the unremitting labors of both Farmer and Channing for seven long years before a system was developed sufficiently reliable for public use. Even then all the troubles were not eliminated, but experience and the continuous vigilance of the gifted projectors finally brought about success. It must be borne in mind that these early systems all included the striking of great alarm bells, controlled by electrical mechanism. This is considered a simple matter at the present time, but at that comparatively remote period—Channing's first suggestion was made barely a year after Morse's first telegraph line between Washington and Baltimore went into operation—all these trifling details had to be worked out from the very beginning with absolutely no data to go by. Gamewell, who shortly after appeared upon the scene, had his attention first directed to the fire alarm telegraph by Prof. Joseph Henry, who had helped many another to achieve fame and fortune by his advice and counsel so freely given to all comers. Gamewell at once recognized the great importance of the fire alarm telegraph, and lost no time in acquiring the rights in all existing patents on the subject. Armed with these he gathered about him a corps of able electricians and mechanicians, among them Edwin Rogers, James M. Gardiner, Moses G. Crane and John Polsey, and together these men developed much of what is now standard fire alarm apparatus, or which formed the basis for it. Nor must the name of Charles T. Chester be forgotten, to whom is due the automatic alarm box, invented in 1856,—previous to that time all signals being transmitted by hand in various ways. The first "non-interference pull" was also due to Stephen and Charles T. Chester. Then followed invention after invention, including many for controlling the doors of alarm boxes so as to prevent mischievous interference, and a variety of others, relating to central office, and to engine house apparatus, the combined effect of which has resulted in bringing about the marvelous results in rapidity and precision of transmission of fire alarms now the pride of most American cities. Mr. Bosch is of the opinion that one of the problems in fire alarm telegraphy has not yet been satisfactorily solved, and that is, making the signal boxes readily accessible to anyone in case of fire, and in a way that will not at the same time render it easy to give false alarms. Thus even in this well worked field the ultima Thule has not yet been reached, and there is still chance for the aspiring inventor.

THE SUCCESS AND FAILURE OF SCIENTIFIC MEETINGS.

THE enterprise of the British Association for the Advancement of Science in crossing the ocean this year, appears to have been rewarded by a very successful meeting, the papers being good, the attendance large and the hospitality profuse. As at Montreal in 1884, so at Toronto in 1897, the Canadians have extended a hearty welcome alike to kin from across the sea and to kin from across the border, and the result will be a stimulus to scientific work in the Dominion and to general interest in it. As a matter of fact, England is not a little desirous just now, and wisely so, to cultivate her friendly relations with the big "colony"; and while some among us feel that Canada will never attain the full growth of manhood until it is independent and self-governing, there is no cause for regret in the prosperity of the Dominion under English rule and encouragement, and none in the stability of political institutions under which her people are happy, even if they do not increase in number very rapidly. It is not unlikely that the British Association is in Canada with a political arriere pensee, but that is its own business, and meantime it has attended assiduously to its chief object in life, the promotion of science under the British flag, with most undeniable vigor and success.

When we turn to the meeting of the American Association at Detroit and contrast its meagre attendance with the bustling crowds at Toronto, the contrast is a little too sharp to be altogether pleasing. It might be said that it was so small a gathering because many of the members preferred this year to go and meet their British brethren; but, on the other hand, it is small every year, and many of the British brethren were public spirited enough to go to Detroit. What is the reason for the general failure of the American Association meeting as a scientific and social function? Why should not the membership be as large and the attendance as good as with the British Association?

There are reasons, of course. This is a large country and a great many people cannot travel long distances for such a purpose, either because of the strain on health or because of the drain on pocket. But even the local attendances are not large, nor do the local notabilities turn in bodily and do all they can to give the stamp of society to the affair. It may be that the explanation is the absence of the wealthier people, who to-day are interested largely in culture and are college bred—at the seaside, on the mountains, or in Europe. We take it for granted that most of the big houses in Detroit, or Buffalo, or Washington are closed at this season of the year.

One fact that stands out prominently in the British Association meeting is that it rallies not only the grand body of

scientific talent where its strength lies, but the leaders who do most to give ideas, catchwords and data to the whole army of investigators. Now, without desiring to offer the slightest ground for offence, or to make invidious distinctions between great men and men not quite so great, we must say that the American Association somehow does not get all its big stars out. It is possible that the "star" idea is as much to be deprecated for a scientific meeting as for a theatre, but can it be said that the British Association meetings suffer in any sense from the active participation of those who loom as large in the public eye as do Lord Salisbury, Sir John Lubbock, Lord Kelvin, Lord Lister, and others who now are sharing busily in the work at Toronto?

Other scientific and engineering societies besides the American Association in this country appear to experience the same difficulty in getting out their leaders, so that perhaps the trouble is not one for which the association alone is to be criticised, as for an individual and curable weakness. To go no further afield than electricity, it may be noted that neither Mr. Brush nor Mr. Edison has ever shared in a meeting of the American Institute of Electrical Engineers, of which both are members; and yet that growing society, in influence, dignity and desire to promote a high standard is deserving of all the encouragement that personal presence can give. Prof. A. G. Bell has never attended a meeting, and when he was elected its president did not even take the trouble to prepare an address inaugural or otherwise. Mr. Tesla has given the Institute some magnificent contributions, but he rarely shows up at the meetings. Mr. Edward Weston was president, but has never, out of his inexhaustible funds of endless experiment and deep observation, made a single notable contribution to the transactions of the Institute. Prof. Elihu Thomson is the only man among the electrical leaders who can be counted upon as a steady and ever willing participant in Institute work. Yet when one turns to England, the proceedings of the Institution of Electrical Engineers are found to bristle with the names of well known leaders, and their interest in its work never flags. We fancy that a not dissimilar condition and comparison could be discovered in regard to other societies here and those abroad, but it should suffice to distinguish these two conspicuous examples. We think it would be really interesting and helpful to know why, in science and engineering generally, as shown by the facts to which we have drawn attention, there is less genuine solidarity and intercommunion here in democratic America than in a country like England, which we are apt to regard as aristocratic chiefly because it has a titled class. Is it that the leaders, as an aristocracy of intellect, desire to hold aloof, and prefer to do so, because they are leaders; or far more likely, is it that something is lacking in the work of such societies to bring these men in closer relations with them? No doubt the British Association has its own problems, but it does at least justify its existence by getting out the captains of science, who thus help it advance scientific work in public estimation by their names, by the lustre of their achievements and by their frequent presence at its gatherings.

INSTRUCTION IN ELECTRICAL ENGINEERING.

THE rapid changes which are constantly going on in what are termed the modern sciences and industries have now become so commonplace and are taken as such matters of course that they scarcely attract attention. Yet we find that even among some of the oldest sciences the changes are not less rapid and almost revolutionary. Those who will take the trouble to inspect the work of an up-to-date public school and compare it with the work of a generation back will realize the changes that have taken place in pedagogic methods during that brief period. Indeed, there is hardly a meeting of teachers at which there is not some scheme of teaching proposed diametrically opposite to what has been deemed good standard practice for many years past. An illustration of this diversity of views among educators may be distinctly traced in comparing the contributions by Prof. Jackson and Prof. Owens, which appear in this issue. On the one hand we note the laying out and adherence to what might be called a fixed course, so far at least as it refers to one department of electrical college work, while on the other the aim is to give the student as much latitude as is possible, and in a large measure to let him work out his own education, as it were. There are arguments that can be brought to bear in favor of both methods, and we will be glad to open our columns to a discussion of this subject in the hope that it may lead to the elucidation of the results attained by the differing methods adopted in our various colleges devoted to electrical engineering.

THE POSTAL IN MEXICO.

IT is a matter of more than usual interest that the Postal Telegraph Company should at last have made its way into Mexico, and in a very effectual manner. It is announced that the two great railway systems, the Mexican National and the Mexican Central have turned their telegraph lines over to the Postal people, and thus become essentially and integrally a part of an American telegraph system. The Postal Company has been building Southward for a long time past, to the Mexican border, with a view to the closing of the arrangement just mentioned. It is now in touch with the Mexican Central system at El Paso and will presently connect with the National system at Laredo.

As telegraphy to Mexico has hitherto been under Western Union control by means of the submarine cable, there will now be two good competitive services available to the American and Mexican public, and lower rates are in order. The message rate from New York City to the City of Mexico will be $1.85 for ten words, and the cable rate from the City of Mexico to London will be reduced from 60 cents a word to 39 cents. An increase ought to follow not only in the amount of telegraph business, but in those lines of trade affected favorably by quickness and cheapness of intercommunication.

FAN MOTOR FANCIES.

IT is reported that during periods of dullness on the stock exchange, the brokers have amused themselves by numbering the blades of their fan motors, and betting on the number to stop at a given point. This game, with interesting variations, has, however, died a natural death since business began to pick up, and the brokers are now occupied with the vagaries of "dollar wheat" and the ups and downs of the "industrials." We do not know that electricity has, in reality, suffered any loss by this diversion. The cool weather this summer, while a boon to most people, has certainly kept the fan motor trade from booming, and in view of the low range of the thermometer in July and August it is strange that inventive genius should have been bestowed on the problem of making the fan motor breeze any cooler than it would be naturally. But the fact is that one user of a fan has put his motor in an ice box so contrived that the air passes over the melting ice and is expelled by the fan through an opening in the side of the box so that a little ice goes a long way in the shape of an extremely cooling breeze. This reduction to a small scale of practice pursued elsewhere on the large is creditable and will doubtless be imitated by those for whom even this frigid summer has not been cool enough.

ELECTRIC TRANSPORTATION

ELECTRICITY AS A MOTIVE POWER ON ELEVATED RAILWAYS.—IV.

BY PROF. S. H. SHORT.

(Concluded.)

MOTOR Best Suited to Elevated Service.—As there is neither dust nor water to contend with, the motor can be left entirely open, for the free circulation of air over the armature and field magnets, and not only thorough ventilation, but 20 per cent. more output, can be obtained from a given machine in this way. The open motor can be much more easily inspected and kept free from oil and grease.

The accompanying diagram (Fig. 17) shows the form of motor which we have designed for elevated railway service. This motor is intended to be taken apart by running the truck from under the car, and lifting the upper half of the magnetic ring by means of an overhead crane; this exposes the armature, left with its bearings in the motor frame, which is journaled to the car axle at one side and supported by the truck bolster at the other side. The motor frame has cast, integral with it, the lower half of the magnetic ring. Each half of the magnetic ring has two pole-pieces, wound with a few turns of heavy copper ribbon, so that the magnetic system of the motor is symmetrical, and of very large sectional area, to provide for the rapid acceleration control, which will be discussed later.

The magnetic ring is large in diameter and the axle is made to pass inside the ring, between the magnet coils, so that the distance between the gear centers is short. This makes the gears small in diameter, and gives a large clearance above the stringers inside the rails.

The armature is especially large and heavy, provided with deep slots to secure the bar winding, which makes but one turn per commutator bar. By this means the self-induction of the armature windings is reduced to a minimum, and there is a very low voltage between the commutator bars, providing for perfectly sparkless commutation.

Bronze is used for both the armature and axle bearings, and the lubricant is oil instead of grease. The brasses are so arranged that the thrust caused by the gears brings the shafts against solid unbroken surfaces. The oil is stored in cellars and is carried to the bearings by means of waste, which wipes the entire length of the shaft within the brasses.

Provision is made at the ends of the bearings to collect all of the oil which may escape and return it to the cellars to prevent a drip on the structure and street beneath. The bearings are made exceedingly long and the shafts are large in diameter, the pressure per square inch being reduced to the very low value of 37 pounds. The armature bearings are solid and are lifted out of the motor together with their oil cellars when the armature is removed by an overhead crane. The gear housing is made of heavy cast iron in halves, the lower half being permanently fastened to the motor frame, while the upper half may be lifted off independently by the overhead crane. The housing is grease-tight and the gears run in oil. The entire motor is cast from the best quality of steel.

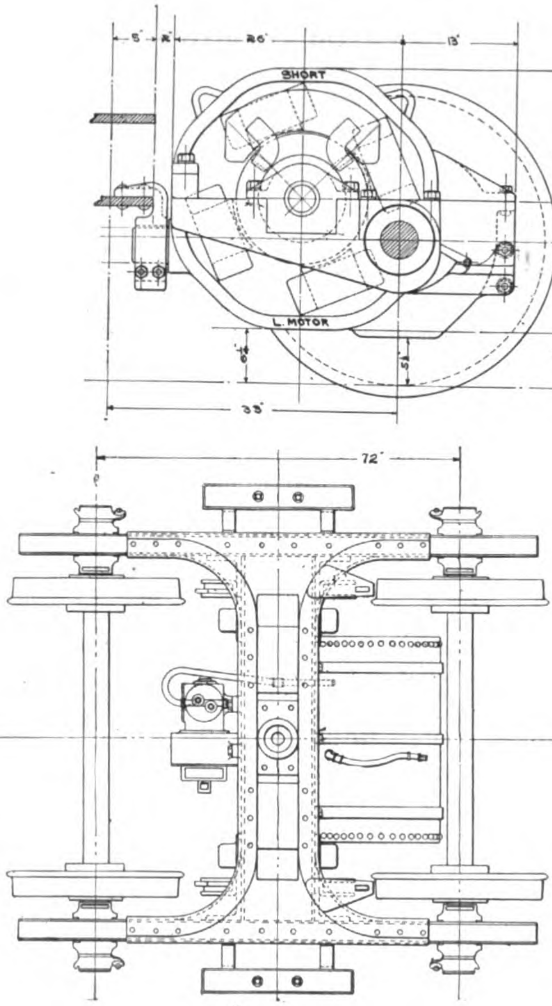

FIG. 19.

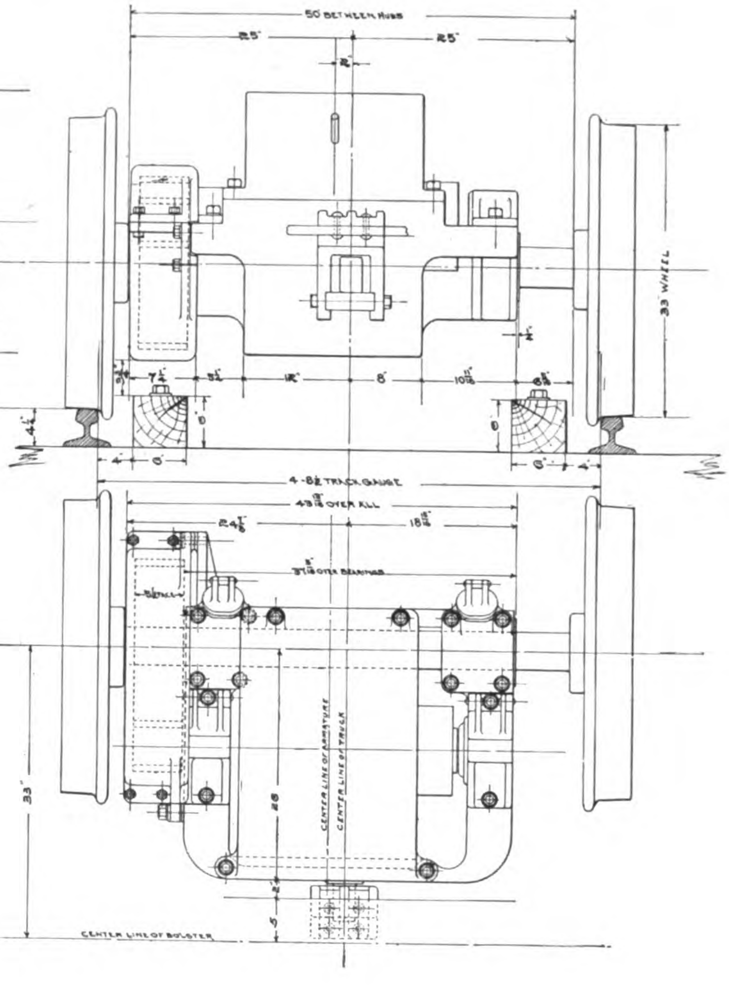

FIG. 17.

The Control.—The motors are controlled by a series-parallel controller, which provides for keeping a constant current through each of the motors, of such a quantity as will just avoid slipping the wheels during the time of acceleration. We have named this the maximum, constant current acceleration controller. In order to accomplish this kind of a control, the counter e. m. f. of the motors is prevented from rising until the train has reached the maximum speed at which it is desired to operate it. The counter e. m. f. is then

instantly raised to a point which reduces the current to a quantity which produces a horizontal effort sufficient to overcome the resistance of the train and maintain a constant speed.

The accompanying diagram (Fig. 18) shows the acceleration curve of an ordinary series-parallel controller and two series motors; also a curve of the constant current method of control, with two motors of the same size. The advantages of this latter method are apparent in the decrease of the schedule time and the decrease of power consumption.

The Brakes.—Westinghouse automatic air-brakes are used on all trains, with a brake applied to every wheel, enabling a train to be brought to a stop with a negative acceleration of 3 feet per second, which is not disagreeable to passengers.

The train pipe for this system of brakes is fed with air from a main reservoir attached to one side of the truck bolster (Fig. 19) of the idle truck of the motor car, as illustrated in the engraving. On the other side of the truck bolster is attached an electric motor air compressor, as illustrated. The motor is arranged to automatically stop and start under the influence of the varying pressure in the main reservoir. The object in putting the air-compressing apparatus on the truck instead of on the car body is to avoid the disagreeable noise due to the operation of the pump; and to facilitate repairs, as the truck with its entire air-compressing outfit is run out from under the car in the same manner as the motor truck.

Third Rail Feeder System.—A third rail of varying section should be mounted throughout the entire length of the road on substantial insulators. Heavy rails should be laid near the station and gradually taper off to the ends of the road. For most "L" roads it is not necessary to use auxiliary feeders of any kind, as the entire power necessary to operate all trains can be carried by the third rail. This rail should be placed on one side of the track with its head some inches above the track rails, so that sliding shoes, made of cast iron and attached to the trucks, may slide freely along their upper surface (Fig. 20).

The table (Fig. 21) below shows the amount of power which rails of different sections can carry, with a drop of 100 volts per mile, when all the power is delivered at the end of the mile. **Of course, the same amount of power can be distributed with the same drop over two miles of track. The table also shows the relative cost of this method of distribution as compared with copper feeders.**

Bonding.—All rails, as far as practicable, should be in 60 feet lengths. The third rail, as well as the track rail joints, should be bonded by a flexible copper bond, attached to the under side of the foot of the rail by means of a number of rivets, and the area of contact with the rail should be sufficient to provide that not more than 100 amperes per square inch should be required to pass through the joint between the steel and copper. The sectional area of the bond must be one-sixth the sectional area of the rail itself. The track rails should be electrically connected frequently with the elevated structure. Care should be taken that all joints between cop-

per and steel should be made with clear bright surfaces and no space be left to admit water or air to corrode the joints.

ELECTRIC TRAMWAYS WITH STATIONARY ACCUMULATORS.[1]

BY LUDWIG SCHROEDER.

IN February, 1896, an experiment was made on the Zürich-Hirslanden electric tramway to see if it were possible to connect the accumulator battery directly across the machine terminals without using the automatic cell switch. This trial proved very successful, and as a result the 270 cells have been connected directly to the machines during the last three-quarters of a year without any means of regulation other than that afforded by themselves. The connections are those shown in Fig. 1, and they are extremely simple. The voltmeter has been omitted so as not to confuse the diagram. The ammeter, A, is of the type with its zero in the center of the scale so that it indicates whether the cells are charging or discharging.

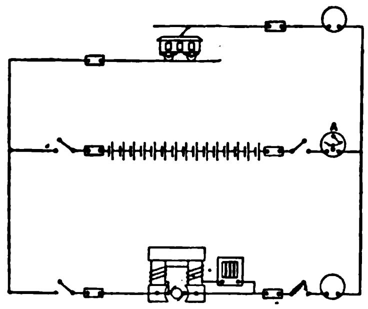

FIG. 1.

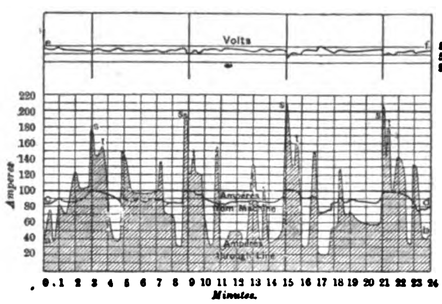

FIG. 2.

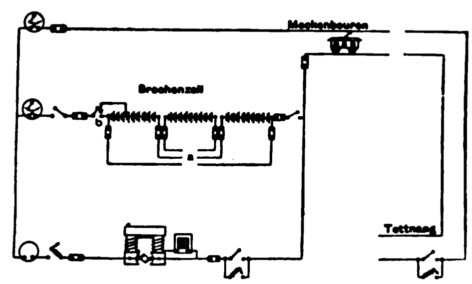

FIG. 3.

Fig. 2 shows the current and pressure curves obtained with this arrangement on the system in question, during a period of 24 minutes. The curves are self-explanatory: a b is the curve of current supplied to the trolley wire so that the shaded area is the consumption in ampere minutes. It is seen that the current varies from 20 to 210 amperes, and the six minutes' service is clearly shown by the peaks, s s, of the curve. One can also notice by the pairs of peaks, s and t, that the times of departure are not practically simultaneous at the two ends of the line. The curve, c d, represents the current generated by the machines. The mean value of this is 90 amperes, and the current only varies between 72 and 102 amperes. This maximum difference occurs only once in the 24 minutes, and during the greater part of the time the current remains between 85 and 90 amperes. The curve, e f, representing the pressure is very regular. The maximum variation is between 535 and 560, and these extreme values have only occurred once during the 24 minutes.

The above mentioned battery has been in use two and one-half years (during the last nine months of which it has been connected directly to the dynamo terminals), but it shows no trace of wear.

The author next describes the Tettnang electric railway. The demand for electric light and power supplied from the railway power station increased to such an extent that it became desirable to add to the plant, especially as the traffic on the line had also considerably increased. On the advice of Herr Oscar von Miller a battery of 318 Hagen cells was put down. This battery may be discharged for half an hour on the railway circuit, at 30 amperes, while momentary currents of 160 amperes are permissible. The full output of the machine, viz., 72 amperes, may be used as charging current. The connections are shown in Fig. 3, from which it is seen that they are on the same principle as the connections for the Zürich-Hirslanden line, shown in Fig. 1. The machine is compound-wound, but for working in parallel with accumulators the series-winding is disconnected. This machine is built for a pressure of 700 volts, and as this pressure may not be exceeded, the cells are only charged to 2.2 volts each during the day, which suffices for ordinary working. The cells must, however, be fully charged once a day, and a switch is provided at a for the purpose. The battery is divided into three groups of 106 cells; two of these are charged in series, while the other one remains switched out. At equal intervals of time the position of the three groups is changed, so that all get equally charged. The charging takes from one-quarter to one-half an hour, and it is done either before traffic on the line starts or after it has ceased.

There is a reserve steam plant at the other end of the line in case of failure of the hydraulically driven plant at the main power station at Brockenzell. The cells can also be worked in parallel with this plant, but then, as there is a drop of 50 volts in the main, 25 cells are switched out by means of the switch, b.

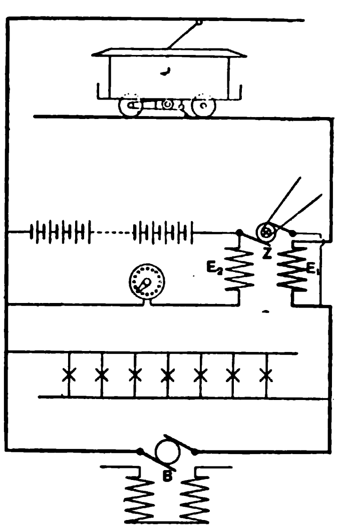

FIG. 4.

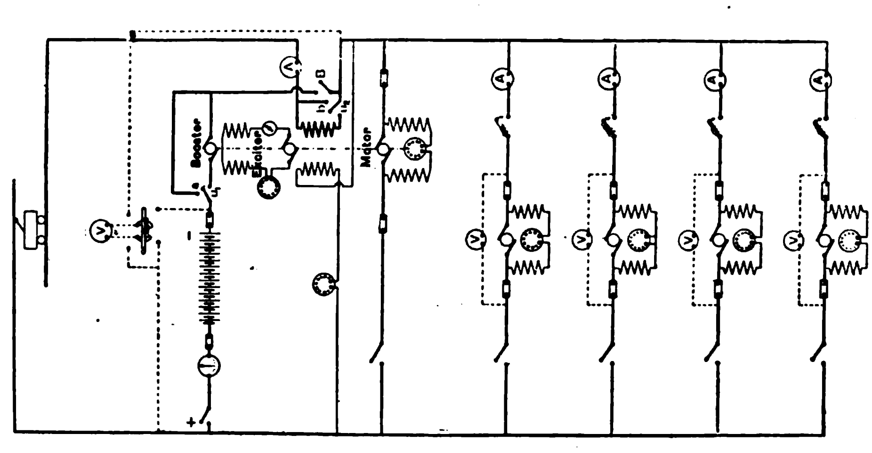

FIG. 5.

The Remscheid Electric Tramway.—The Remscheid electric line, which was built in 1892 by the Union Electricitäts Gesellschaft, has always excited considerable interest in view of the uneven nature of the ground. There is a difference in level of 350 feet, between two points on the line only 1½ miles apart, part of this section including a gradient of 10.6 per cent. There are, moreover, only 60 yards level on the whole 6.8 miles of line. To keep the pressure constant an arrangement, devised by Messrs. Siemens and Halske, was used. Fig.

[1]Abstract of a paper read before the Elektrotechnischer Verein.

4 is a diagram of the original method, and Fig. 5 the modification employed at Remscheid.

Referring to Fig. 4, the belt-driven booster, Z, has two field-windings in opposition to one another. The winding, E_2, is excited by the batteries, and the winding, E_1, is traversed by the current flowing from the dynamo. If the demand for current for the line is equal to the output of the chief generator, B, the battery must neither give nor receive current and the pressure at the terminals of Z must be zero, i. e., the currents through the two windings must neutralize one another's action. If the demand for current is less than the output of the machine, B, the effect of the winding, E_2, is the stronger, and in consequence the machine, Z, generates current in the right direction for charging the cells. If a current above the normal is required from the line, the winding, E_1, changes the polarity of the machine, Z, so that this adds to the pressure in the battery circuit, and the cells supply current to the line.

The arrangement at Remscheid only differs from this by the employment of a small additional machine, which serves as exciter for the booster, and is provided with the double field-winding instead of the booster itself. This is because of the size of the booster, which is designed to give 600 amperes at 100 volts for ten minutes. These two machines, the booster and its exciter, are driven by a direct-coupled 90 h. p. motor. In the diagram the motor is shown at the end of this combination. This has been done for clearness; actually the motor is between the exciter and the booster, which are directly coupled to it. The battery can be connected directly in parallel with the main machines if required, by switching on the switch, B, switching u_1 to a, and u_2 to b, and thus disconnecting the booster. The two latter switches are connected to one handle; they must be moved over at a moment when the current from the battery is exactly 0, so that it is best to stop the booster first.

The battery consists of 250 cells of the Hagen make, having a capacity of 648 ampere hours at a discharge rate of 216 amperes, though a current up to 420 amperes may be taken from them.

The dynamos are compound-wound, but a trial showed that they could generate 150 amperes at 500 volts without their series-windings, so they are used as ordinary shunt machines now that they are working in parallel with batteries.

At Remscheid it has been calculated that over 11 tons of coal are saved per week since the traction system was altered. But it is not only the coal consumption that must be considered, 200 h. p. of the dynamo output has been saved, and the battery that effected this saving only cost half as much as the machines which have been set at liberty, and are now available for any further increase in the load.

TELEPHONY AND TELEGRAPHY

INDEPENDENT TELEPHONY IN NEW ORLEANS.

MR. J. J. FOWLER, who was formerly with the Great Southern Telephone and Telegraph Company, is now busy organizing an independent telephone exchange, as already announced in these columns. This concern is to have a capital of $250,000 and will be known as the Louisiana Telephone, Telegraph and Construction Company. His intention is to place telephones in business houses at $50 per annum for the service and in private residences at $35 per annum. This includes the cost of the erection of the lines and maintenance of the instruments and apparatus, and these rates are to apply to all persons in the populated portions of the city. Mr. Fowler expects to place every share of the new company in New Orleans, so that the property shall be owned and operated there. He feels perfectly satisfied that the investment will yield dividends of at least 6 per cent., if not more. The $250,000 of capital stock will be amply sufficient to cover the city with the system and place the wires in the central portions of the city underground. Not one dollar is to be reserved for promoting interests, the entire capital stock being represented by stockholders, who have the privilege of selecting all the officers who will, in their judgment, best carry out their wishes, both as to the manner of investment and the results to be obtained from the permanency of construction and service. The construction of exterior lines, instruments, etc., as well as the equipment of the central exchange and all auxiliary offices are to be of the very highest standard. The service will consist entirely of metallic circuits.

Relative to placing the wires underground, Mr. Fowler says he apprehends no difficulties from the nature of the soil and other objections advanced by parties who oppose an underground system. He intends to have all the wires for a large area underground. He says this is entirely feasible by laying a system of subways, into which will be laid cables of, say, 200 wires each. Beyond this district pole lines are to be run, which, however, are to be changed into underground lines whenever the requirements, or the city authorities will so direct. In order that these pole lines should not be overloaded a system of branch offices will be established, which will be connected with the central exchange by a system of trunk lines, thus reducing to a minimum the number of wires leading from one section of the city to another.

Relative to the system of subways and cables which Mr. Fowler proposes to place underground, he said that while some contended that it was impossible to lay wires underground in New Orleans, he not only felt confident that this could be accomplished, but he had the opinion of the most expert constructing engineers in the country on the feasibility of laying underground wires here with every prospect of success. As regarded the kind of conduits which he would employ he said that he would use cypress. Its porousness would not be detrimental, and the lasting qualities of the wood underground are too well known to require repetition. Each cable is to contain 200 wires (100 subscribers), while the subways will be large enough to admit of expansion. Provision will be made for 3,000 subscribers. At every square (or where the blocks are short), every two squares, manholes will be located, which will be, say, 5½ feet deep. The present time would be most opportune for laying the underground system, as New Orleans is on the eve of making great permanent improvements in the matter of sewerage, drainage and permanent pavements, and the system will have been laid out of the way before the other improvements were commenced. The cost of maintaining the underground system would be much less (it would be as 6 to 18 or 20) in proportion, a fact which would also cut quite a figure in the charges for the service. This means a saving of $60,000 per annum to the telephone subscribers of New Orleans, and this, with the earnings of the company, would all remain there, as the citizens would own the property.

LONG DISTANCE TELEPHONY AND THE RAILROADS.

IT does not seem within the scope of the ordinary human understanding, says the Cincinnati "Enquirer," that the immense passenger traffic of a railroad of the marvelous extent of the Pennsylvania Company or any similar line could be visibly affected by the long distance telephone. Such a statement ordinarily would be received with ridicule and laughter by the common railroad officials, and treated with contempt by the higher authorities. Yet no lesser personage than James McCrea, the head of the western branches of the Pennsylvania system, told President M. E. Ingalls, of the Big Four and Chesapeake & Ohio railroads this week that the business of the famous limited train of their company had been practically ruined by this instrument. These two gentlemen met yesterday in consultation in reference to commercial relations between the two lines, and during their negotiations the subject of the falling off of the passenger traffic of the country was brought up. Various reasons were given, when Mr. McCrea made his decidedly sensational statement. It is well known that the Pennsylvania limited was originated and run in a measure for the benefit of the brokers and business men of Chicago and the Northwest, who needed quick action in the matter of travel. Their trips to New York were taken upon occasions of utmost importance, when time meant thousands of dollars. By means of the limited the broker or business man was taken to New York in the quickest possible way. There was no delay in getting there, it meant rapid business talk and equally as quick a return to Chicago. The business man was willing to pay the price assessed for the development in rapid transit displayed by the limited.

Then came the introduction of the long distance telephone. People were slow in realizing its benefit. Slowly but surely they have, however, acquired its significance. A broker in Chicago or a grain dealer in that city has an idea for a big deal; he telegraphs to New York asking for certain information: "Call me up by long distance telephone and give me your answer." The result is that for $15, perhaps $20, a talk is held with the New York man. He has had an opportunity to concentrate his expressions to the shortest possible statement; he has even jotted it down, and at the proper time calls up his

man and transacts business. So it is done every day. Mr. McCrea gave as an evidence that in the past he found it necessary to spend twenty days in the month on the road, leaving but ten days of his time at home. By aid of the long distance telephone now he has reversed matters; it requires but ten days of his time upon the road, giving him twenty days at home. The matter, when it came to the attention of an "Enquirer" representative, was presented to various business men upon the chamber of commerce and upon Third street. Half a dozen grain men, who have been in the habit of making two and three trips a week to Chicago, said: "Oh, yes, that has been the case with me; I have for $3 or $4 been able to transact business which otherwise meant a trip to Chicago or St. Louis." The same way with commission dealers and brokers. They indorsed the statements of the grain men and stated that the telephone had saved them numerous trips. The financial brokers and bankers of Third street use the telephone continually now; in fact, it is quite the feature of several of the more prominent brokers since they have their long distance telephone connections, but it has never become so prominent a factor in railway circles as has been stamped by Mr. McCrea's utterances. If it practically interferes with a great train like the limited a revolution is certainly taking place in railroad affairs.

NEWS AND NOTES

WELLMAN HOISTING MAGNETS IN THE ILLINOIS STEEL WORKS.

FROM time to time attention has been called to the desirability of employing the lifting power of magnets in various shop operations; and apparatus to that end has been devised and used both here and abroad, as noted in our columns. We now show the practical and successful type of apparatus of this class supplied by the Wellman-Seaver Engineering Company, of Cleveland, Ohio, to the Illinois Steel Company for their plate mill; and the illustrations are from the plates to be lifted the electric connection is made by means of an ordinary switch, placed in a convenient position in the operator's cage. The magnets are so designed that they are practically waterproof, and can be used for handling plates and other material out of doors. The double pole magnets in use at the Illinois Steel Company can handle with

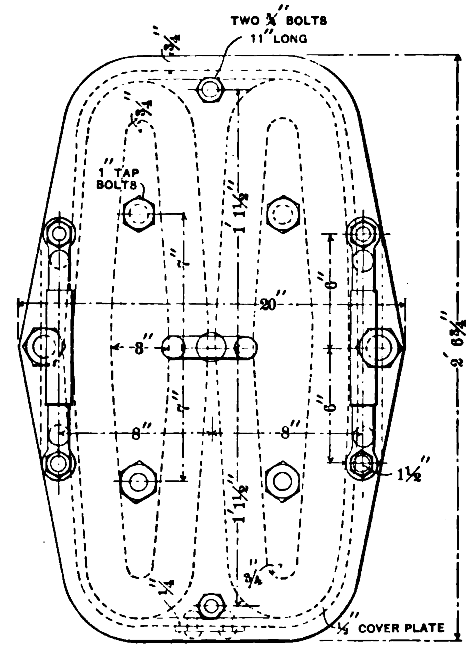

FIG. 2.

safety 5 tons, and only take about 4 amperes, with a 240 volt current.

Considerable difficulty was experienced on first starting the magnet in picking up single plates from a pile, as the magnetism was carried through several plates. The operator, however, in a very short time became expert in operating the switch. After the magnet has been lowered on to a pile of

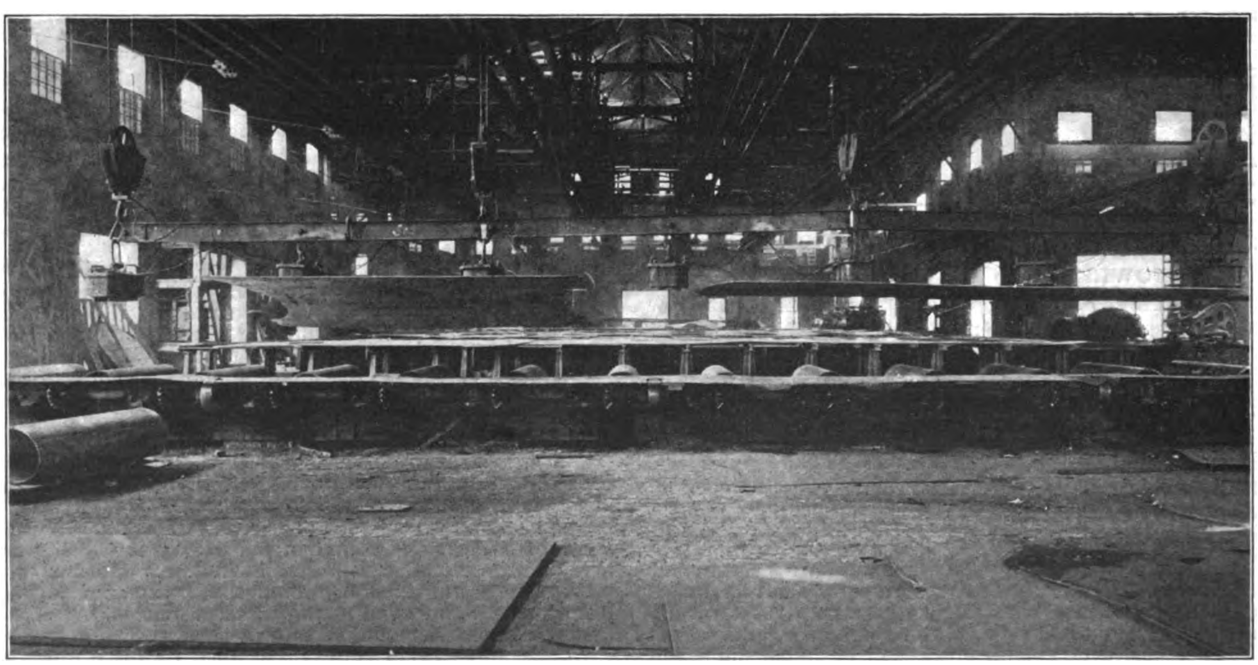

FIG. 1.—WELLMAN HOISTING MAGNETS IN ILLINOIS STEEL CO.'S PLATE MILL.

the "Iron Age." Magnets for this work in connection with an electric traveling crane are specially well adapted for handling plates, as the connections to the magnet are placed on the bridge of the crane in the same manner as the connections for the operating motors, and after the magnet is placed on plates and several plates have been taken up together, the operator simply pulls the switch out, thereby breaking the current for an instant. By this operation one or two plates can be dropped off at each breaking of the current, residual magnetism enough remaining in the plates next to the mag-

net to hold them until the current is again switched on. This operation is continued until only one plate remains attached. The concentric pole magnet, Fig. 4, was specially designed for handling hot plates and ingots, and there has been no difficulty in handling a 6,000 or 8,000-pound ingot at a low red heat.

The use of electric magnets has been very limited. But

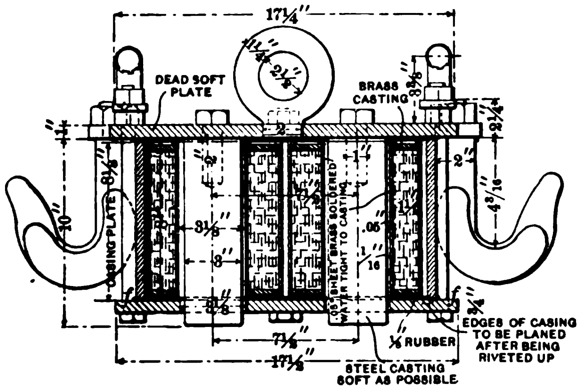

FIG. 3.

where the iron or steel to be handled is in such shape that it is possible to get a good contact, there is no doubt but that it is the most economical and rapid method of handling. A great many concerns have been afraid to put magnets into use on account of the apparent danger of dropping the material and thus endangering the men who may be at work. In the years of experience the Wellman-Seaver Company have had they do not know of a single case where any one has been injured by the material dropping, and they firmly believe it is the safest way possible to handle certain classes of

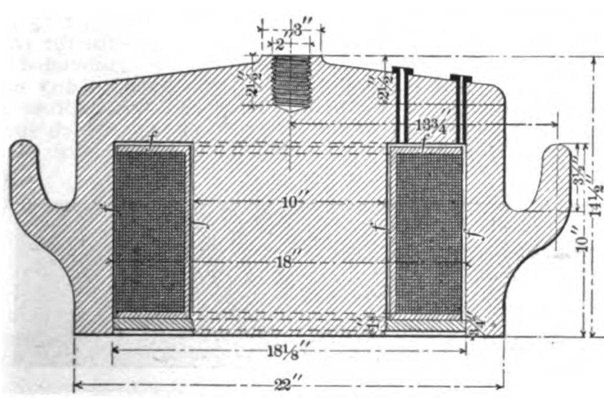

FIG. 4.

iron and steel product. The magnets are so designed that it is impossible for the men that are placing the magnets to receive a shock. It may be noted that in using magnets of this type at the Otis Works in 1889 to load billets from a stock-yard pile on to cars, it was found that the billets were too entangled in the heap to pull out with sufficient freedom.

PROF. SHORT'S DEVICE TO SECURE LOW RELUCTANCE.

AN interesting patent, No. 588,491, has just been issued to Prof. S. H. Short on his invention which has the object of furnishing a multipolar dynamo, motor or rotary transformer in which there are combined two advantages hitherto regarded as rather incompatible, namely, a very low reluctance or magnetic resistance and an absence of the hitherto consequent counter-currents in the armature, which cause bucking when the machine is started. Prof. Short has discovered that if he surrounds the magnetic circuit at various points in its length, outside the armature, with metallic bands or other closed conductors of very low electrical resistance, serious troubles are overcome and the desired result is attained. His drawing and patent specification illustrate and describe bands preferably of copper placed along the field yoke between the field magnet cores. They can be first formed and placed in the mold for the yoke, so that when the yoke is cast the surface will be flush. The principle involved is that an induced current results in a band in one direction when the magnetic flux is increased, and in the opposite direction when it is decreased. This induced current reacts upon the magnet core and reduces or increases the flux. The fluctuations of the magnetic flux and the consequent evils are therefore practically stopped. The same reasoning applies on similar lines to a motor or a rotary transformer.

THE BREAKDOWN OF THE COAL BINS IN THE EDISON STATION AT PATERSON, N. J.

A SINGULAR accident at the fine station of the Edison Electric Illuminating Company, of Paterson, N. J., last week deprived a large number of customers of light and power and suspended the operation of a good many miles of trolley lines which drew current from that source. It will be remembered that the station in question was described and

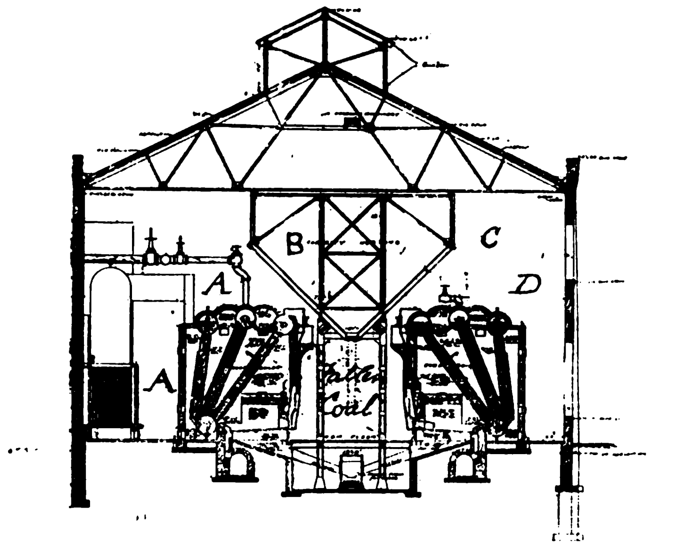

FIG. 1.—DIAGRAM, PATERSON, N. J., EDISON STATION BOILER ROOM.

profusely illustrated in The Electrical Engineer, of December 9, 1896. The accident was the sudden breakdown of the coal pockets in the building, over the boiler room, large quantities of coal thus literally swamping the boiler room. Fig. 1 shows the scene by diagram. Fig. 2 is from a photograph taken about forty-five hours after the accident, when the major portion of the coal and debris had been cleared out of the way.

The bin was designed and constructed about eighteen

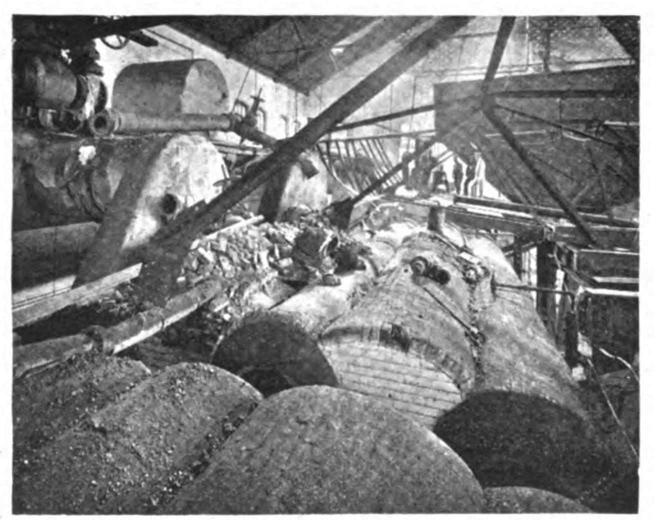

FIG. 2.—A VIEW OF THE COAL BINS AFTER THE ACCIDENT, PATERSON, N. J.

months ago. The space on the right, Fig. 1, is vacant, no boilers having as yet been placed on that side. At the time of the accident (which occurred at 4:30 p. m. on the 14th inst.) the bin contained approximately 1,000 tons of coal. The bin burst near the center on the right, at D, the moving mass of coal ripping off the entire side. The trussed ties thus losing their support, the left side of the bin with its contents of several hundred tons of coal toppled over on the boilers, carrying with it every foot of the 12-inch steam mains and every

boiler connection. The coal banked up against the boiler front 10 feet high, nearly filling the space, A, between the economizers and boilers and covering the feed-pumps. Probably 200 tons of coal remained in the wreckage on the boilers and bottom of bin. One hundred and fifty men in relays were immediately set to work shoveling coal which had to be moved practically three or four times. A force of men from the Passaic Rolling Mills, Paterson, and from Milliken Bros., New York, were promptly at work taking down the wreckage, while four sets of steamfitters were at work taking down pipe here, an elbow there, removing good flanges from broken pipe, the whole going to make up a complete connection for one boiler. Within twenty-eight hours from the hour of the collapse, General Manager W. M. Brock, had No. 1 boiler of the battery of six under steam and by midnight the city arc lamps and incandescent system were in service, and the street railways started on schedule time Monday morning.

By building a temporary 8-inch main from No. 1 boiler to No. 6, they were able to place the latter in service by 9 p. m. on the 16th. It might be interesting to note that during the greater part of Monday boiler No. 1 developed continuously from 1,400 to 1,700 h. p. at 150 pounds pressure under forced draught. It is doubted whether hotter fires were ever seen under a boiler. Based on the engine duty of about 18 pounds, the boiler would have a nominal capacity of about 830 h. p. The iron plating of the bin was pierced by every safety valve of five of the boilers.

LORD KELVIN AND THE NIAGARA POWER TRANSMISSION.

BY ORRIN E. DUNLAP.

LORD KELVIN, past president of the British Association for the Advancement of Science, has been to Niagara Falls, and in company with Dr. Coleman Sellers has looked upon the big turbines and generators. It will be recalled that Lord Kelvin, then Sir William Thomson, was president of the International Niagara Commission established in London, England, in June, 1890, for the purpose of examining plans for the then proposed Niagara development, and that the Niagara Falls Power Company acted upon the suggestions of the commission. Despite Lord Kelvin's prominent connection with the project in its early stages, he had never until Sunday, August 14, looked upon the results of the development other than in pictures. For this reason, if for no other, this initial visit of the noted scientist and electrician to the great power plant at Niagara was replete with interest. Dr. Sellers, who also was a member of the International Niagara Commission, and who is now president of the Niagara Falls Power Company, was at the Cataract House to be among the first to greet Lord Kelvin on his arrival at the Falls from New York. The greeting of the two great men was full of feeling. When they last met it was on Lord Kelvin's native shores, and now Dr. Sellers was the host representing his company at the request of President Adams, of the Cataract Construction Company, to extend courtesies to the members of the British Association.

Over two decades of years had passed since Lord Kelvin was at the Falls before, and what changes those years had wrought! The year was 1876. The idea of using the waters of the Niagara was in many minds. Much had been written upon it. Several comparatively small factories were using power from the hydraulic canal, but the total amount of power so used was very small. The above facts were recited by Lord Kelvin by way of introduction to the interview, and then he was asked: "You were originally inclined to believe that power could be transmitted much more economically by some new appliance rather than by shafting?"

"Yes. At the fiftieth annual meeting of the British Association in York, I gave estimates of appliances by which power could be transmitted from Niagara Falls to a distance of 300 miles by a single wire, but instead of a single wire 300 miles long, the calculation would be applied to transmit 150 miles by wire and return, insulated metallic circuit, and I showed that it was only a question of the voltage used what would be the loss of energy in the wire. I gave an estimate on transmission with 20,000 volts, and I think about 20 per cent. would be lost on the way. A voltage of 30,000 would be possible, but neither then nor now would I advise the adoption of so high a voltage as that. There would be no difficulty in using 20,000 volts for transmission to a distance of 20 miles, and a fairly economical transmission to a distance of 40 miles. Forty miles could be realized, but most probably it would be much better for the factories to come to the power, or to come within 10 miles of the power, than to transmit to a great distance."

"You think the future of Niagara Falls is more assured by this power development than by anything else?"

"Yes. I think we already see the beginning of what is destined to grow into a great industrial district around Niagara Falls, within ten or twenty miles of Niagara, both on the United States side and on the Canadian side. I do not prophecy anything, but I anticipate industry will advance on both sides of the border, and that the power of Niagara will be taken advantage of to any extent we may imagine. I have witnessed with great interest the advancement made by the Cataract Construction Company with the project of using 120,000 h. p., and the actual realization of a large part of the project. Also the prospect in the near future of 50,000 h. p. being actually generated by ten turbines and transmitted to distances from five to twenty miles—it may be further—and to shorter distances."

"These units of power are what you recommended to the International Niagara Commission? It was decided by the commission that 5,000 h. p. would be a possible amount of power to be transmitted?"

"I was chairman of the commission invited by the Cataract Construction Company to meet in London and consider the project. That commission decided, or concluded, that a 5,000 h. p. unit for development of the power by a single turbine was practicable, although the greatest amount of horse-power given by a single turbine before that was only 1,500 h. p. From this it will be seen that the Cataract Construction Company and the Commission had the courage to make a great step in advance of anything that had been done before. Still this was only looking into the future, and the commission left the development to the Cataract Construction Company after considering plans that had been given them by many of the greatest constructors of turbines and of electrical machinery. After carefully considering what could be done either by electricity or compressed air or by hydraulic pressure for transmitting power, the Commission strongly recommended the choice of electrical transmission in preference to any other known or conceivable method. They did not express any opinion as to the nature of the electrical current which should be used, as they believed at that time that the state of the art was one of transition. It might be in the future turned one way or the other, and no one could project exactly what could be developed.

LORD KELVIN'S AUTOGRAPH IN NIAGARA POWER REGISTER.

"Very much pleased to see the great success here achieved as the result of courageous undertaking and originality of invention and skillful design and construction. K."

"The Cataract Construction Company have carried out the project left in their hands, and have taken advantage of great developments in electrical engineering, which have grown up since the sittings of the commission. In the result as we now have it in the power house of the Niagara Falls Power Company, and in the several factories, chiefly at present electro-chemical, which have sprung up around it within the last four years; in the electric supply of the tramways between Niagara Falls and Buffalo on the one side and Lewiston on the other, and in the local lighting of Niagara Falls, we already have a splendid installment of the work projected and now in progress for utilizing the great natural power of the place.

"Positively, I have been intensely interested in all that I have seen here during the last three days, and I can scarcely find words adequate to express the great admiration which I feel for the inventiveness, the scientific care in design and the skill in execution which I have witnessed in the power house, and in some of the factories supplied by it. These results and the smooth and uninterrupted success in the actual working during the two years which have passed since the first of the dynamos commenced running, in August, 1895, are largely due to the hearty and harmonious co-operation of the great electrical construction companies and their generous

rivalry in assisting the scientific staffs of the Cataract Construction Company and the Niagara Falls Power Company."

"The originators of the work so far carried out and now in progress hold concessions for the development of 450,000 h. p. from the Niagara River. I do not myself believe any such limit will bind the use of this great natural gift and I look forward to the time when the whole water from Lake Erie will find its way to the lower level of Lake Ontario through machinery doing more good for the world than that great benefit which we now possess in the contemplation of the splendid scene which we have presented before us at the present time by the waterfall of Niagara. I wish I could think it possible that I could live to see this grand development."

A well known gentleman who was present and heard Lord Kelvin's words stated that it might be well for him to insert a saving clause in that statement, the gentleman having in mind the past unnecessary alarm about the beauty of the falls being impaired by power development, but Lord Kelvin warmed up as at no previous time in the interview and said:

"No. I do not hope that our children's children will ever see the Niagara cataract."

His enthusiasm over what he had seen while in the great power house was no doubt finding its way to expression, and these few words well portray how he enjoyed his visit at the Falls.

"I may add," continued he, "if it is not irrelevant to the questions you have put to me, that I look forward to a revival of both life and prosperity in the Highlands of Scotland, the present crofters being succeeded by a happy, industrial population, occupied largely in manufactories, to be rendered possible by the utilization of all the water-power of the country. The people there say that to do away with the Falls of Foyers is to replace the porters and guides of tourists by an industrious people. It seems to me a happy thought that the poor people of the country will be industrious artisans, rather than mere guides and assistants to tourists."

"Am I to understand that it is your belief that the limit of power transmission with present day apparatus is twenty miles?"

"Forty miles. Rather let the factories come to the power than the power go to the factory."

"How about lighting New York City by Niagara electricity?"

"Of course, with electric lighting that is another question. You cannot bring New York to the Falls to be lighted, but you can bring factories to the Falls to be operated."

"Do you think it possible, then, to light New York from Niagara?"

"It would be too expensive. It could be done, but more than half of the current would be lost in transmission."

"Will electrical apparatus, in your opinion, undergo great changes?"

"No doubt there will be great improvements. There has been enormous improvement during the last five years, and it is not unlikely that the next five will be less progressive than the last."

"In your opinion, what is most needed in the electrical science to-day?"

"More and more of it."

This ended the interview, and Lord Kelvin and party departed with William B. Rankine, secretary of the Cataract Construction Company, for a trip over the great gorge road and the Canadian Park road, where he had another opportunity to see what electricity is doing for the Niagara locality.

Mr. W. B. Rankine. Lady Kelvin. Dr. Coleman Sellers. Lord Kelvin. Dr. J. F. Bottomley. Mrs. Bottomley.

LORD KELVIN AND PARTY AT NIAGARA.

LETTERS TO THE EDITOR

LAMP RESISTANCES FOR ARCS IN MULTIPLE.

I note in your issue of the 19th of August an article headed: "Wasted Current in Arc Lamps," with the suggestion as to the substitution of an incandescent lamp for the dead resistance.

I beg to herewith hand you a price list of series incandescent lamps, by which you will see we have for some time past been making just such a lamp.

CONVERSE D. MARSH,
President Bryan-Marsh Company.

New York City, Aug. 20, 1897.

SOCIETY & CLUB NOTES

THE NINETEENTH ANNUAL CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

THE nineteenth annual clambake given by Mr. Eugene Phillips, as president of the American Electrical Works, Providence, R. I., to the electrical fraternity took place on Saturday, August 21, at the Pomham Club, near that city. There were 292 guests present, many from distant cities, showing the high esteem in which Mr. Phillips is held and the popularity of his clambake. After a pleasant half-hour's trolley ride from Providence the invited guests found themselves at the club, which is most delightfully situated on the Providence River. Lunch was served from 11:30 until 2 p. m., during which time the guests enjoyed themselves with all sorts of in and outdoor pleasures. Immediately before the clam dinner all of the guests arranged themselves in a group and were photographed. At about 2 o'clock p. m. the clam dinner, a decidedly elaborate affair, was served in the spacious hall of the club house. Every one present was by this time in a very jovial mood, and the speeches made were certainly an index to the happy frame of mind all were in. Mr. Phillips, speaking first, greeted his guests in a most cordial manner, and stated he was "heartily glad to see each and every one," and further on commented upon the enormous strides made in the electrical field. Mr. Samuel Powers, of the New England Telephone Company, was called upon to act as toastmaster of the occasion. Representing the "telegraph interests," Mr. Samuel A. Duncan, of the Postal Telegraph Company, was thereupon requested to make a speech. Mr. Duncan responded in a humorous way, connecting the Phillips family, and Mr. Eugene Phillips in particular, with the Morse system of telegraph. Mr. H. F. Wood, of the West End Street Railway of Boston, dwelt upon the many miles of electric railways built in this country and the cheapness of transportation. Responding to the toast of "Electrical Journalism," Mr. Robert F. Ross made a neat speech. His Honor Mayor McGinnis, of Providence, then spoke regarding the many large manufacturers in that city and the successful establishment of which Mr. Phillips is the president. In behalf of the Electric Light Association, Vice-President Stetson responded in a decidedly humorous vein. In like manner Mr. Stetson was followed by Capt. John C. White, who spoke in high praise of Mr. Phillips and commented at length on his enterprise and generosity. The after-dinner speeches closed with remarks again by Mr. Samuel Powers, the toast-master, thanking Mr. Phillips, and the bake ended with many cheers by the assembled guests. The day was an ideal one for the event, and will certainly be remembered by all who were present. Handsome souvenir canes were distributed.

OFFICERS OF THE AM. ASSOC. AD. SCI.

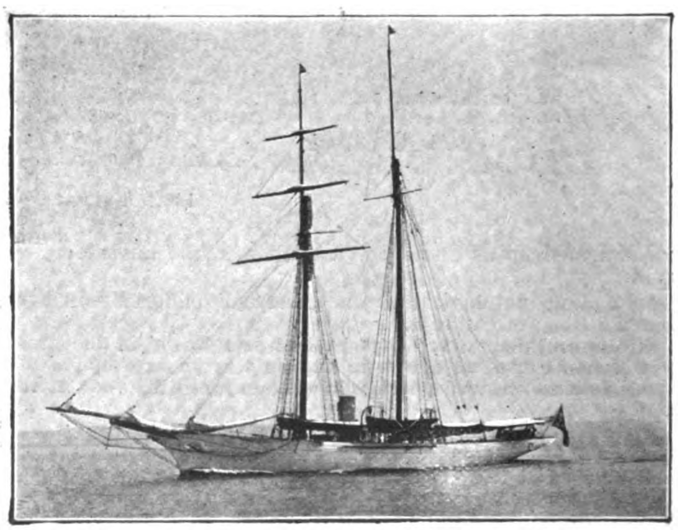
The new officers of the American Association for the Advancement of Science are the following: President, F. W. Putnam, Cambridge, Mass.; permanent secretary, L. O. Howard, Washington, D. C.; general secretary, D. S. Kellicott, Columbus, O.; council secretary, F. Bedell, Ithaca, N. Y.; treasurer, R. S. Woodward, New York; vice-presidents, mathematics and astronomy, E. E. Barnard, University of Chicago; physics, Frank P. Whitman, Adelbert College, Cleveland; chemistry, Edgar F. Smith, University of Pennsylvania; mechanical science and engineering, M. E. Cooley, University of Michigan; economic science and statistics, Archibald Blue, director of Bureau of Mines, Toronto, Canada; secretaries of the sections, mathematics and astronomy, Alexander Ziwet, University of Michigan; physics, E. B. Ross, Wesleyan University; chemistry, Charles Baskerville, University of North Carolina; mechanical science and engineering, William S. Aldrich, University of West Virginia; economic science and statistics, Marcus Benjamin, United States National Museum, Washington, D. C.

TORONTO MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE Toronto meeting of the British Association began last week at the University Building, Toronto, and continues during the present week until Wednesday. The attendance is very good, the number registering being not less than 1,500, inclusive of a great many Americans. The regular work of the Association appears to be fully up to the record, and has been accompanied by several social entertainments and functions of a delightful character. Last Saturday was an exceedingly busy day at the power house of the Niagara Falls Power Company, at Niagara Falls, the occasion being the visit of the members of the British Association, who went over from Toronto, Ont., to see the installation. It was about 11 a. m. when the first of the delegation arrived, and they were rapidly followed by others. When the members and their friends reached the power house, they were met by Dr. Sellers, president of the Niagara Falls Power Company, W. B. Rankine, secretary of the Cataract Construction Company, Resident Engineer W. A. Brackenridge, Superintendent Lincoln, Mr. W. K. Dunlap and others connected with the plant, and were escorted about the interior of the building, every part being most carefully explained by the always courteous officials. The generators, the governors, the switchboard and other parts of the installation all came in for careful inspection, after which the party boarded a train and were carried over the Junction Railway and to some of the plants thrown open to their inspection. All were intensely enthusiastic over what they saw, and some took occasion to inscribe in the autograph book of the company their appreciation of the attention Dr. Sellers had shown them. Some of the visitors on leaving the power house turned their attention to scenic Niagara and hurried away to the beautiful State reservation. Many of the party remained at the Falls over Sunday, returning to Toronto Monday morning. Abstracts of the more interesting papers will appear in our columns next week.

THE SAFETY CO.'S EXCURSION ON THE HILDEGARDE.

A NOVEL and very delightful excursion was given last Wednesday, August 18, by the Safety Insulated Wire and Cable Company to a large number of their electrical friends, on board the fine auxiliary steam yacht "Hildegarde," formerly the property of the Prince of Wales, and placed at the disposal of the company by its president, Mr. B. M. Whitlock, rear commodore of the Atlantic Yacht Club. The party went down to the waters off Sandy Hook, where all conveniences were handy for fishing, and the net results of the efforts of the whole party were 50 blue fish, some flounders and a few sharks. For the general amusement, music was given by the Neapolitan Mandolin Quartette, by colored minstrels and by a humorist. Refreshments were provided with lavish hand, and the comfort of the guests was assiduously looked after by Mr. Whitlock, General Manager L. F. Requa, and the staff of



THE AUXILIARY STEAM YACHT "HILDEGARDE."

the Safety Company. Hearty resolutions of congratulation and thanks were presented to the graceful entertainers for a charming day, before the party left Sandy Hook, and on the return of the yacht, further hospitality was extended in the shape of dinner at the Atlantic Yacht Club House. The "Safety" brand of excursion was voted an immense success. It should be added that the invitations were most artistic and will certainly be preserved by all as souvenirs.

MASS. STATE CONVENTION N. A. S. E.

The second State Convention of the National Association of Stationary Engineers was held at Engineers' Hall, Boston, Mass., on August 6, when a large amount of routine and other business was disposed of. The secretary's report showed a large and flattering growth. In the evening a complimentary dinner was given to the delegates at the Castle Square Hotel. The following day a trip was made down the bay to the drainage stations and Deer Island. Other excursions also took place. The attendance was very good. The press was represented by Messrs. F. R. Lowe, editor of "Power"; J. O. Sullivan, Boston "Globe," and A. J. Guernsey, The Electrical Engineer. The president of the association is Mr. P. H. Hogan, the engineer of the Institute of Technology.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.

The fifth annual meeting of the Society was held last week at Toronto, in connection with the meeting of the British Association. The president, Dr. H. T. Eddy, was in the chair, and papers were presented on methods of teaching, by Prof. W. H. P. Creighton; calculus for engineering students, by Prof. F. W. McNair; teaching of machine design, by Prof. J. J. Flather; chemical technology, by Prof. H. Bunte, of Germany; chemical engineering, by Dr. J. M. Ordway; technical versus literary training, by Prof. T. C. Mendenhall; French and German for engineers, by Prof. A. N. Van Daell; electrical engineering study, by Prof. R. B. Owens, and helping students in specific research, by Prof. C. D. Marx. The paper by Prof. Owens is given in this issue.

THE STOCK MARKET

CHEERFUL NEWS.

THE most noteworthy feature in current affairs has been the great rise in the price of American wheat, which has already crossed the dollar mark, and at this writing is well on its way to another quarter.

In view of this fact, more than in regard to any other condition, the volume of general trade is growing and prices are hardening. Bank clearings are 40 per cent. heavier than in the corresponding week of last year, and railroad earnings are steadily improving. The number of business failures last week was 214, or half of what it was in the same week of the panic year, 1893. Silver has definitely parted company with wheat, and the two prices are shown absolutely to have no relationship. Silver to-day is lower than ever, being only 52 cents for commercial bar, per ounce.

Quotations on the New York stock market have been steady since the last great rise a week ago. Of Western Union, 28,-545 shares were sold, closing at 91¾. General Electric sold around 36½, on 9,940 shares. American Bell telephone is steady, at 237, on sales of a few score shares. New York Metropolitan Traction new 5s. are firm around 113. New York Edison is steady at 123½, and Chicago Edison is about the same figure.

COPPER is firm around 11¼ cents for Lake ingot, 10⅞ to 11⅛ for electrolytic and 10⅝ for ordinary casting stock. Statistics show a falling off in production of not less than 3,000 tons below the average for the first half of the year.

STEEL RAILS are quoted at $21 and upward for light sections. Heavy rail mills are said to be behind their orders. Bessemer pig iron is 25 cents higher.

EDISON COMPANY, New York City, show a gain in July of $1,763 net for the month and $88,945 for the seven months, being a very substantial increase over 1896.

INVENTORS' RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUGUST 10, 1897.

Alarms and Signals:—

SIGNAL RECEIVING APPARATUS. W. F. Banks, Milford, Conn., 587,693. Filed October 1, 1896.
A two-part apparatus, the first part being arranged to respond to all impulses, and the second to only special impulses.

SWITCH BOX. Jas. C. Mock, Wilkinsburg, Pa., 587,746. Filed June 10, 1896.
Employed for making and breaking the track-circuits in accordance with the position of the switch-rails.

BURGLAR ALARM. C. Coleman, Chicago, Ill., 587,931. Filed January 11, 1897.
An electrical barrier consisting of overlapping parallel insulating-strips and parallel conducting-strips secured to the insulating-strips.

ELECTRO-PNEUMATIC ALARM. Geo. W. MacKenzie, Beaver, Pa., 587,998. Filed April 15, 1897.
Designed to operate by atmospheric disturbance.

ELECTRIC ALARM. R. Penney, National Military Home, O., 588,-004. Filed January 2, 1897.
Adapted to produce a loud musical sound, for use on street cars.

Batteries, Secondary:—

PROCESS OF TREATING ALLOYS FOR MANUFACTURING ELECTRODES. L. P. Hulin, Modane, France, 587,829. Filed December 21, 1894.
Consists in alloying a heavy metal with barium, and treating the alloy with a liquid to eliminate the barium and produce a spongy-metal electrode.

Conductors, Conduits and Insulators:—

INSULATOR FOR WIRES. Geo. Ashby, Hamilton, Can., 588,048. Filed December 24, 1896.
Consists of a stem provided with an arm having a lug, a bolt connected with the stem and a cylindrical piece mounted upon the bolt.

Dynamos and Motors:—

WIRE FOR ARMATURE-WINDINGS. S. H. Short, Cleveland, O., 587,764. Filed March 19, 1896.
Composed of more than two wires twisted together and having plane surfaces in contact at every point.

ARMATURE FOR DYNAMO-ELECTRIC MACHINES. S. H. Short, Cleveland, O., 587,765. Filed March 29, 1897.
Embodies a laminated core, the inner edges of the laminations being straight, and adjacent layers being lap-jointed.

ELECTRIC MOTOR. Julius L. Thoma, Kansas City, Mo., 587,769. Filed August 17, 1896.
Embodies duplicate armatures one above and the other below the poles of the field-coils.

COMMUTATOR AND LEAD. S. H. Short, Cleveland, O., 587,868. Filed March 12, 1897.
Method of insulating the commutator-bars and their leads.

FIELD-MAGNET FOR DYNAMO-ELECTRIC MACHINES. S. H. Short, Cleveland, O., 587,869. Filed March 12, 1897.
Composed of solid magnet-cores, each having one end furcated by intersecting slots, combined with a yoke cast about the furcated ends of the magnet-cores.

ARMATURE. S. H. Short, Cleveland, O., 587,871. Filed March 13, 1897.
Comprises a slotted core, and an end ring at each end of the core having peripheries adapted to support the armature-inductors beyond the core.

APPARATUS FOR GENERATING CONSTANT ELECTRIC CURRENTS. Chas. N. Black, New Haven, Conn., 587,921. Filed April 26, 1897.
Comprises a multi-circuit constant current dynamo, a steam engine having a fixed point of cut-off and an automatic steam cut-off.

Electro-Metallurgy:—

ELECTROLYTIC APPARATUS. Wm. Thum, Newark, N. J., 588,-035. Filed October 8, 1896.
Adapted for the deposition of metals in a crystalline form.

PROCESS OF TREATING SULFID ORE. B. Mohr, London, Eng., 588,076. Filed June 14, 1897.
The pulverized ore is treated with acid sodium so as to obtain a solution of sulfate of zinc depositing the zinc by electrolysis, recovering the acid alkali sulfate, and treating the insoluble residue obtained by the lixiviation for recovery of the other metals.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. J. McLaughlin, Chicago, Ill., 587,750. Filed August 26, 1895.
Feed mechanism.

Measurement:

ELECTRIC METER. Jean F. De Bauw, Brussels, Belgium, 587,-798. Filed April 26, 1897.
Solenoid instrument. Details of construction.

Miscellaneous:—

APPARATUS FOR ELECTROLYSIS. A. E. W. Boucher, Prilly, Switzerland, 587,696. Filed August 13, 1896.
Consists in the use of an electrode having combined in one structure a positive and negative element insulated from one another.

APPARATUS FOR DETECTING ELECTROLYSIS OF UNDERGROUND PIPES AND LOCATING TRANSMISSION LOSSES. H. T. Brown, New York, N. Y., 587,698. Filed January 27, 1896.
Details of method.

APPARATUS FOR CAUSING CHEMICAL CHANGES IN GASES. N. Vander Sleen and A. Schneller, Alfenoudshoorn, Netherlands, 587,770. Filed January 18, 1895.
Details of construction.

ELECTRO-DEPOSITING DEVICE. John Bossard, Dubuque, Ia., 587,782. Filed June 1, 1896.

Employs a screw threaded shaft above the tank upon which the holders rest and are advanced by its rotation.

PROCESS OF AND APPARATUS FOR MANUFACTURING METALLIC PEROXIDS AND CAUSTIC ALKALIES. L. P. Hulin, Modane, France, 587,830. Filed December 26, 1894.

Details of process.

DEVICE FOR EXAMINING JEWELS BY ROENTGEN RAYS. Elihu Thomson, Swampscott, Mass., 587,883. Filed September 4, 1896.

Consists of a source of Röntgen rays, a support for the jewel, a fluorescent screen beneath the support, a mirror at an angle beneath the screen, and adjustable eye-pieces for observing the reflected image in the mirror.

PROCESS OF AND APPARATUS FOR MAKING METALLIC CARBIDS. I. L. Roberts, Brooklyn, N. Y., 588,012. Filed Sept. 14, 1896.

Consists in moving beneath a horizontal electric arc the metallic compound and carbon to be converted, and in reflecting the heat of the arc downward.

PROCESS OF AND APPARATUS FOR ELECTROCHEMICAL TREATMENT OF STRAW OR OTHER FIBROUS MATERIALS. G. H. Pond, Ashburnham, Mass., 588,084. Filed Sept. 15, 1896.

The straw is treated by the electrochemical decomposition of a solution of chlorid of sodium.

METHOD AND APPARATUS FOR ELECTROCHEMICAL TREATMENT OF FIBROUS MATERIAL. G. H. Pond, Ashburnham, Mass., 588,085. Filed Feb. 12, 1897.

Similar to above.

ELECTRICALLY-OPERATED LOOM. E. D. Chaplin, Cambridge, and H. G. Talloran, Boston, Mass., 588,101. Filed July 16, 1896.

Details of construction.

THERAPEUTIC APPARATUS. H. Sanche, Detroit, Mich., 588,-091. Filed July 7, 1892.

Consists of a connecting filament of porous material with absorbent terminals.

IGNITER FOR EXPLOSIVE ENGINES. Philip Murller, Decatur, Ill., 587,747. Filed Dec. 18, 1896.

Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. S. D. Field, Stockbridge, Mass., 587,720. Filed Nov. 21, 1891.

Employs a conductor of flexible magnetic metal suspended on insulators within a slotted conduit.

ELECTRIC CONTROLLER. S. Harris, Johnstown, Pa., 587,733. Filed Jan. 7, 1897.

Comprises a rotable drum carrying contacts, and a coil surrounding a part of the drum and electrically connected to any suitable part of the circuit.

TROLLEY WIRE HANGER AND SPLICER. C. K. King, Mansfield, O., 587,740. Filed April 13, 1897.

Comprises a flanged hanger having a slot to receive the trolley wire in which it is retained by rivets.

ELECTRIC RAILWAY. R. L. Caldwell, Cleveland, O., 587,792. Filed Jan. 21, 1897.

Device to insure the trolley wheel taking the proper conductor at a switch.

TROLLEY HANGER. Theo. Fletcher, St. Louis, Mo., 587,805. Filed Oct. 10, 1896.

Comprises a longitudinal flexible strand adapted to be secured to a trolley wire and means for suspending the hanger by the flexible strand.

TROLLEY. S. H. Short, Cleveland, O., 587,870. Filed Feb. 16, 1897.

Comprises a long flangeless roller which is mounted in the forked upper end of the trolley arm.

OVERHEAD TROLLEY SYSTEM FOR ELECTRIC RAILWAYS. S. H. Cauffiel, Johnstown, Pa., 588,053. Filed July 24, 1896.

A structure for cross lines of wire.

ELECTRIC RAILWAY SYSTEM. L. E. Walkins, Springfield, Mass., 588,097. Filed April 15, 1897.

Third-rail system for long roads.

ELECTRIC LOCOMOTIVE. R. Eickemeyer, Yonkers, N. Y., R. Eickemeyer, Jr., executor of said R. Eickemeyer, deceased, 588,-104. Filed May 9, 1892.

Relates to a braking system.

CURRENT-COLLECTING DEVICE FOR ELECTRIC RAILWAYS. R. M. Hunter, Philadelphia, Pa., 588,111. Filed Feb. 4, 1897.

Comprises an insulated undermining and guiding device, and a contact device to collect the current.

ELECTRIC RAILWAY SWITCH. M. J. M. O'Hara, Wilmington, Mass., 587,752. Filed March 27, 1897.

Operated by electromagnets energized by current supplied through the trolley.

ELECTRIC LOCOMOTIVE. Rudolph Eickemeyer, Yonkers, N. Y., Rudolph Eickemeyer, Jr., executor, 588,105. Filed Aug. 23, 1892.

Method of suspending motor to the car.

Regulation:—

AUTOMATIC ELECTRICAL REGULATING DEVICE. E. W. G. C. Hoffman, Charlottenburg, and J. H. F. Görges, Berlin, Germany, 587,822. Filed April 17, 1896.

Employs a clutch to operate a contact controlling the resistance in the dynamo field circuit.

REGULATING ELECTRIC MOTORS. A. G. Davis, Washington, D. C., 587,937. Filed Nov. 17, 1896.

A method of increasing the torque of a tandem motor system, consisting in neutralizing by a phase-advancing device, part of the lag of the intermediate circuits.

MEANS FOR CONTROLLING ELECTRIC MOTORS. S. H. Short, Cleveland, O., 588,021. Filed May 7, 1896.

Means whereby a variable counter electromotive force in the motor circuit can be generated and utilized to regulate the amount of current flowing to the motor.

Switches, Cut-Outs, Etc.

LIGHTNING-ARRESTER. Edw. M. Hewlett, Schenectady, N. Y., 587,816. Filed March 16, 1897.

Of the magnetic blow-out type.

CIRCUIT-BREAKER. H. Lemp, Lynn, Mass., 587,838. Filed April 3, 1897.

A contact device for induction coils, comprising a pair of fixed terminals with a bridge consisting of a rotatable disc nominally closing the circuit.

Telegraphs:—

PRINTING-TELEGRAPH. E. M. D. Andre, Méru, France, 588,046. Filed Oct. 1, 1896.

Apparatus capable of being used either as a transmitter or as a receiver.

Telephones:—

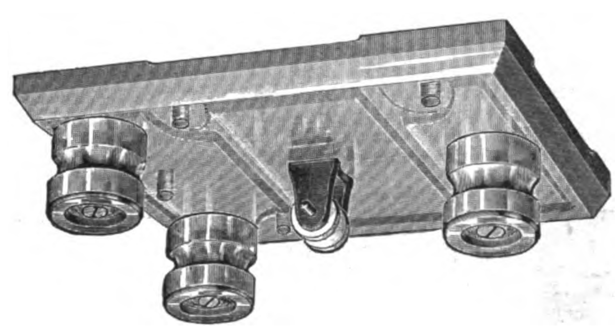
TELEPHONE-BOOTH. E. B. Cadwell, Jamestown, N. Y., 587,700. Filed Oct. 22, 1896.

Constructed with double walls distanced by wooden blocks and interposed sound deadening material between the blocks and the walls.

TRADE NOTES & NOVELTIES

THE McDONALD GLASS HANGER BOARD.

THE insulation of appliances used in high tension series arc lighting is always of the greatest importance, and particularly for inside arc light wiring where a dangerous voltage is carried into the building and directly to the lamp. A large number of arc light hanger boards have been designed from time to time, having for their object better insulation, and, for a newcomer, the McDonald glass hanger, are now claimed the most striking results. As shown in the accompanying illustration, the hanger board consists of glass insulating knobs mounted on a glass base or support. This secures a perfect insulation, which will always remain the same, as moisture or corrosion is not possible. This hanger makes a bright, clean appearance, and can always be kept in that condition. The extra holes shown in the base, allow the board to be used with three insulators, as shown; or with



McDONALD GLASS HANGER BOARD.

only two insulators, one at each end of the board. When a series of lamps is being hung, the board at the end of the series may be used with two insulators, while all the other boards should be used with three insulators. Thus, when the wire reaches the first board it is tied to the first of the two insulators at the double end. From this point a loop is made for the lamp, and the line wire leaves from the other insulator on the double end. This is repeated on each board of the series, until the last board having only two insulators is reached. On this board the line goes first to the insulator at one end of the board, then through the lamp to the insulator at the other end. From this point it starts back out of the building, using as support the free insulators on all of the boards having three insulating knobs. This makes a neat arrangement of the loops and at the same time a perfect insulation of both wires. The McDonald glass hanger board is being placed on the market by the Electric Appliance Company, of Chicago.

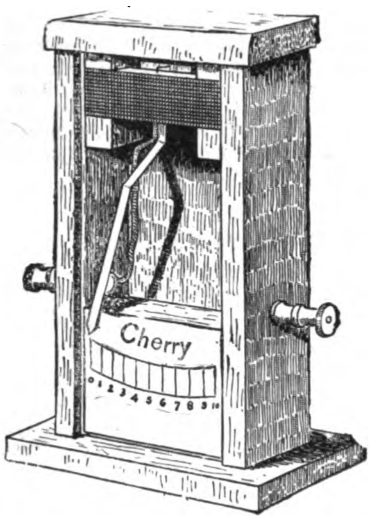
BALL & WOOD ENGINE CO.'S NEW CATALOGUE.

We have received from the Ball & Wood Engine Company, 120 Liberty street, New York, a copy of their new catalogue just issued. It is in oblong form, 9 inches by 12, in a handsome maroon embossed cover, and contains 52 pages of text and illustrations. This company, as is well known, have been highly successful in developing and introducing, first, their simple and compound horizontal engines, their tandem and cross-compound types, and, later, their vertical engines. All these varieties are shown and a great amount of useful and interesting data is given in regard to them and upon the general subject of steam engineering. The views of compound condensing verticals, with valve gear, and those showing the application to dynamos direct or to rope drive, will arrest attention and thought. The company are to be congratulated upon their success and the quality of work and engineering skill with which they have earned it.

CHERRY DIRECT CURRENT AMMETERS AND VOLT METERS.

Electrical measuring instruments are usually beyond the reach of amateurs and students owing to the high price at which they are sold, but the type illustrated herewith is an exception to this statement, its cost being so low as to bring it within the reach of the most slender purse.

As will be seen from the illustration, the instrument consists of a neat wooden case, with a glass face, behind which is the indicating mechanism. The latter is very simple, consisting of a coil at the top of the case, in which is a magnet that takes up a position corresponding to the amount of current passing. To the magnet is attached an index, which moves over a calibrated scale, indicating amperes or volts, according to the winding of the coil used. All metal parts of the instrument are handsomely nickel-plated. The voltmeter reads up to 10 volts and the ammeter up to 10 amperes.



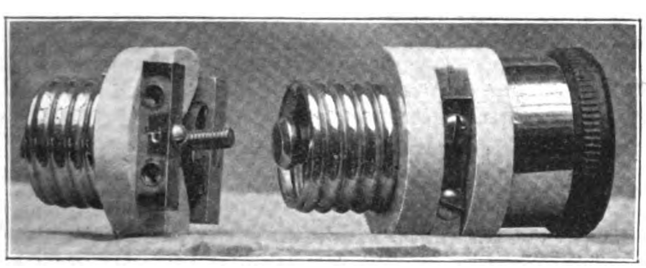
The Cherry Ammeter.

This simple and inexpensive instrument is made by the Cherry Electric Works, 25-27 Third avenue, New York.

THE VETTER CURRENT TAP.

The Vetter current tap, made by J. C. Vetter & Co., 104 East Twenty-third street, New York, is useful wherever there is incandescent electric lighting, as it facilitates the transmission of current to any desired point in the vicinity of the fixture, and thus greatly increases its capacity.

Many offices are supplied with only one or two single wall brackets, and the use of a drop light or fan motor generally means the loss of the lamp, by the substitution of the socket plug for the same at the fixture. The Vetter current tap, however, leaves the lamp where it is, and carries the current to any desired spot; in fact, from a single wall bracket can be obtained by the tap a wall light, a drop light and current for a fan motor. This adaptability makes it very valuable in the sick room, as well as in factories or workrooms, where a good light may be needed directly over an object somewhat removed from the lamp bracket, without losing the light from the lamp bracket itself.



Vetter Current Tap.

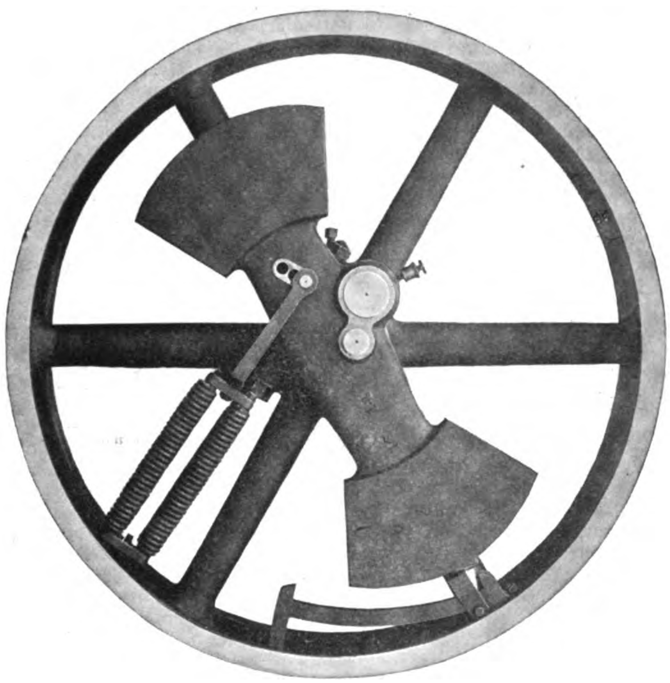
In the medical operating room, the current tap enables the practitioner to have instantly and easily available a portable hand lamp for diagnostic illumination.

The accompanying engraving shows the tap complete, and also the half section. It is made of the best porcelain with hard rubber socket rings.

THE NEW GOVERNOR OF THE BALL ENGINE.

Recent developments in connection with electric lighting in office buildings, insist on such exacting service as to allow only the minutest variation of speed under widely varying loads and changing pressures. Not only must the speed be uniform, but it must remain so during the period of the change. To meet these new and rigid requirements, the Ball Engine Company, Erie, Pa., has, after months of experiment, perfected a governor which in every way fulfils the demands referred to, with the additional beauty of extreme simplicity. This governor, which is an adaptation of the Rites governor system, not only regulates to the very highest degree of perfection, but with an extraordinarily rapid adjustment and without the slightest instability or surging.

Technically stated, the centrifugal element upon which the degree of the refinement of regulation of all governors depends, is combined with an inertia element, relatively so great that instant and extreme changes of load are immediately provided for without waiting for the otherwise necessary manifestation of centrifugal force. The entire governor consists of but a single moving piece, suspended upon one pivotal point, thereby reducing the friction to a minimum, and with no joints to interfere with the best action of the governor. The suspension pin or pivotal point is made of hardened crucible steel. The suspension pin eye is lined with phosphor bronze, and the little lubrication that is required is accomplished by forcing grease by means of a compression grease cup, into a number of recesses arranged around the bore of the bushings. The extreme simplicity of this governor will recommend it to users of engines.



New Ball Engine Governor.

ROWAND'S ORE SEPARATOR.

Mr. Lewis G. Rowand, electrician of the Universal Fire Alarm Company, has recently perfected an entirely new method of electro-magnetic ore separation. The apparatus consists of a belt to carry the ore and two magnets side by side moving at right angles to the belt. By means of a special switch, the magnets deposit the material conveniently which they have attracted as they passed the belt, while the non-magnetic debris is carried further on to be dumped where designated. The machine is specially suited to the separation of ores of low magnetic attractability; and persons wishing to have ores sampled gratis can secure the opportunity by addressing Mr. Henry C. Stewart, secretary and treasurer, 925 Chestnut street, Philadelphia.

NEWTON APPLIANCE COMPANY, 120 Liberty street, New York City, makers of the Newton flush switch, report the following recent large installations of their specialty: Astoria Hotel, Columbia University, the new Delmonico's, Sherry's and the new house of the New York Athletic Club.

RUBERINE PAINT FOR ROOF COATING.

Mr. F. S. De Ronde, general sales agent for the Standard Paint Company, 81-83 John street, sends us the following letter with regard to their ruberine paint: Perhaps it is not known to many of your readers or yourselves, that in addition to the P. & B. compounds and preservative paints manufactured by this company, we also make a specialty of roof coating. We claim to make the best paint in the market for coating and preserving tin and iron roofs. It is the only coating we know of that will effectually fill up large holes that there may be in a metal roof. Suppose for instance, your tin roof was punched full of holes and some one should tell you that they would give you a paint that would fill up these holes. You would no doubt be inclined to disbelieve them. Our Ruberine paint, however, will do this very thing, in addition to which you will note that it possesses extreme elastic properties, which it retains even in very cold weather. We take the liberty of handing you a sample of tin coated with this paint. Same speaks for itself. We should be glad to send to anyone who wishes it, one of these samples along with a good sized package of the paint itself, so that the doubtful ones can make the necessary tests and convince themselves that our material is all that we claim for it. These same remarks as regards to sending samples, also apply to such people as might not know about our P. & B. armature varnish, insulating compounds and tape, if there be any such in the United States. We might say that these latter materials are constantly increasing in popularity, and we are to-day selling more than ever before.

The letter is accompanied by a tin roof treated successfully, beyond any cavil, in the way described.

WESTERN NOTES

CENTRAL ELECTRIC COMPANY, of Chicago, are issuing a very neat and comprehensive small catalogue of electric railway quick break snap fusible switches. These are made in various designs for controlling car light circuits, also in combinations, so that one switch will control two headlights, as well as the car light circuit. The company are distributing these catalogues, to their patrons, and are pleased to furnish them upon request. They are also sending out with these catalogues, circulars of their changeable electric headlights. They have equipped a great many roads with these headlights, and, in every instance, satisfaction has been the result.

J. HOLT GATES & CO., Chicago agents, report good business in the Wagner single-phase alternating current motors. A number are now being installed in the West and giving great satisfaction. This solves the problem of operating power from single-phase circuits. W. D. Ball & Co., consulting engineers, Chicago, who recently installed a motor for pumping water in a large flat building, speak very highly of the performance of the Wagner single-phase motor.

CHICAGO GENERAL FIXTURE COMPANY, 169 Adams street, Chicago, have recently issued a new catalogue of the various electrical fixtures which they carry in stock, which include electroliers, hall lanterns, newels, brackets, portable and ceiling fixtures, pendants, shades and sundry other articles which are used for incandescent electric lighting purposes in offices, buildings or private residences. The catalogue is very tastefully got up and contains a large number of cuts with explanatory reading matter neatly printed in color on plate paper with heavy paper covers. Users of these goods will find a copy of this catalogue useful to have for reference.

ADVERTISERS' HINTS

L. A. CHASE & CO., sole agents for the Elden alternating current circuit breakers, have been receiving numerous communications from users of the instruments testifying to the extreme satisfaction which they give.

ZAMEL ARC LIGHT METER is advertised as a thoroughly reliable device for timing the use of arc lights as well as effecting economy in the consumption of current. The instrument is placed on the market by a company of the same name.

SIEMENS & HALSKE ELECTRIC COMPANY are advertising some new designs and sizes of machinery in the various types which they place on the market.

THE CITY OF NIAGARA FALLS is advertising for bids for the furnishing of arc lights for a period of five years from November 1, 1898. Bids will be received by the Common Council up to and including November 1, 1897.

THE AMERICAN MANUFACTURING COMPANY call attention to the Globe water motor fan, which they are placing on the market, particularly for use where electric current is not available, or the expense of running electric fans is so great as to cause electric motors to be undesirable. The Globe motor is handsome in appearance as well as economical, and is particularly adapted for use in residences.

MR. WALTER C. McKINLOCK, 1108 Fort Dearborn Building, Chicago, is prepared to take hold of a full line of electrical merchandise and is negotiating with several concerns to become their agent. Mr. McKinlock has been connected with the electrical trade for many years, and has a large number of acquaintances and friends throughout the Western territory. He is well known as a man of businesslike nature and sterling qualities.

VOL. XXIV. SEPTEMBER 2, 1897. No. 487.

ELECTRIC TRANSPORTATION

OPENING OF THE BOSTON SUBWAY FOR THE WEST END TROLLEY CARS.

BY H. W. WELLER, C. E.

After twenty-nine months of continuous and unremitting labor, and the grappling with problems which have taxed the energies of Chief Engineer Carson and his corps of skilled assistants to the utmost, the Boston Subway, or at least a part of it, is about to be opened to public travel. This week the cars of the West End Street Railway are to begin to pass down the incline at the Public Gardens and under the Boylston and Tremont Malls of the Common as far as the loop at Park street. Everyone, from the transit commisioners, chief engineers, and contractors, down to the laborers toiling in the dirt, must be congratulated on the achievement of the first half of the undertaking. Many vexatious but unavoidable delays have been experienced, due to strikes and other causes, besides which many special details of construction have had to be worked out as the various necessities have arisen, and all are to be felicitated upon the result.

The portion now open to public travel includes Sections I., II., III., IV. and V. These consist of a two-track subway commencing at the foot of the incline in the Public Gardens just west of the Westerly line of Charles street and crossing easterly under Charles street and running under the Boylston street Mall of Boston Common to the intersection of Boylston and Tremont streets, where the Boylston street station is located. The four-track subway extends northerly from this station under the Tremont street Mall to a point opposite Temple place where the tracks are spread out and form the Park street station with a two-track loop to accommodate the cars, which formerly ran to the old Tremont House and then returned, while the two outer tracks form the north and south bound tracks for the cars running to and from Scollay square, and Adams square and the Union station. The Shawmut avenue and Tremont street cars will enter the subway by the two two-track inclines forming Section 5, between Pleasant and Warrenton streets, and, after a short length of four-track subway merge into a two-track, which connects at Boylston station with the Boylston street line. It is interesting to note that two sub-subways have been constructed in order to avoid grade crossings, one opposite Common street, to carry the south bound Shawmut avenue cars under the Tremont street tracks, and the other at Boylston station, to carry the south bound Shawmut avenue and Tremont street cars under the West Boylston street tracks. This piece of construction is very instructive from an engineering standpoint.

Having thus briefly described the route a short description of the work in detail may be interesting.

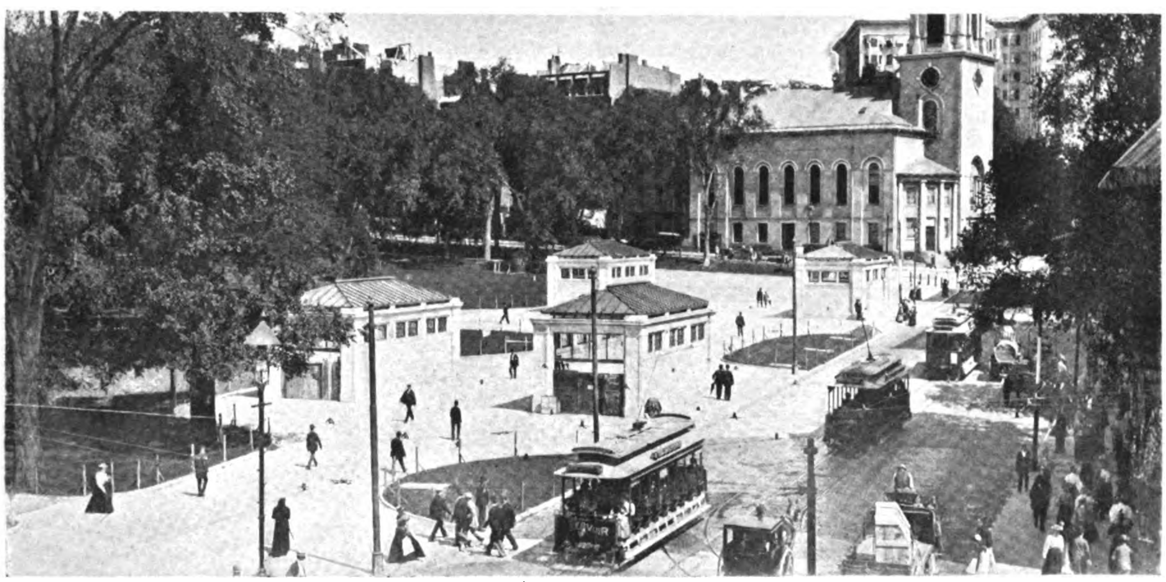
Section I.—On March 23, 1895, the contract for the construction of this section was let to Messrs. Jones & Meehan, and that for the steel to the Pennsylvania Steel Company. The work was commenced at a point in the Public Gardens just west of Charles street, on March 28, 1895.

This section consists of 318 feet of open incline in the Public Gardens, 685 feet of two-track subway from the end of the incline to a point opposite the old Public Library on Boylston street, and 408 feet of four-track subway from the Boylston station under the Tremont street Mall of the Common, ending near West street.

The open incline was excavated in the usual way and substantial granite retaining walls were constructed upon concrete foundations, piling being driven where necessary, with a masonry invert upon which the ballast is laid to carry the ties of the tracks.

In the two-track subway, after the excavations were made in open cut, the masonry and concrete foundations for the steel work were put in and the steel work erected upon them. This portion of the subway consists of steel posts, 6 feet apart along either side, with concrete around and between them. The steel cross beams for the roof are supported on these posts, and trussed or braced across the angles, and the spaces between the beams are filled in with brick arches upon which concrete is laid and waterproofed, and the surface material filled in. The invert is of masonry and cement concrete with an open channel with flag stone cover running along the middle to provide for proper drainage. A vitrified stoneware drain was laid below the level of the invert, to carry any drainage water during construction to the pump well in the Public Gardens. This drain and the various relief drains were afterwards carefully plugged. A four-inch course of concrete was laid below the masonry invert, wherever below the ground water level, and then covered with an asphalt layer extending to and joining the asphalt waterproofing behind the side walls. The concrete forming the side walls was carefully plastered with Portland cement and a coating of asphalt applied, and this asphalt waterproofing was continued over the roof.

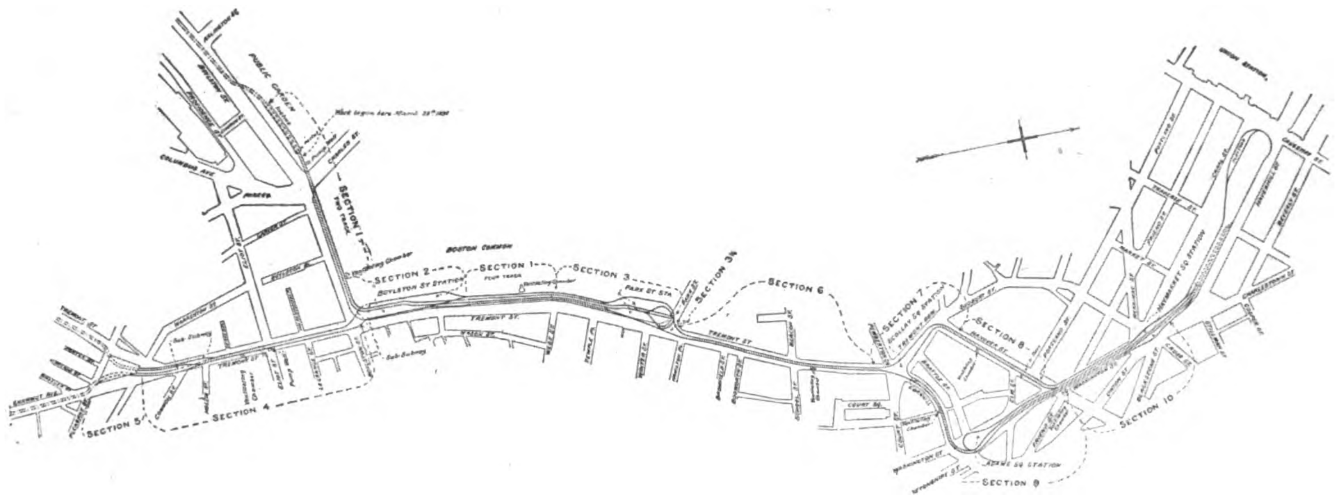
In order to further protect the steel from moisture a vertical course of ribbed tiles was carried up outside the waterproofing



Boston Subway Station Entrances, Park Street, Boston.

to the height of the ground water level, and behind this again was laid a course of brick covered with asphalt. Every 6 feet a 2 inch stoneware pipe was laid through the side walls from the bottom of the ribbed tile to the inside of the subway, thereby preventing any water from collecting behind the walls. The pump chamber in the Public Gardens is connected with the adjacent street sewers by an 18 inch drain, with the necessary manholes. An automatic back flap valve is provided to prevent the passage of water from the sewer back to the pump chamber.

The four-track subway consists of an open excavation the full width of the work, the opposite banks being braced against each other, across the trench, during the construction of the side walls. At the commencement, three trenches were made down to the grade, one on each side and one in the middle for the centre line of columns, but it was soon found practicable to open the entire width at once. The footing stones for the columns or posts were laid on concrete, and the iron work, consisting of the three longitudinal rows of columns supporting the roof beams, were erected upon them. From the hollow in the grade, south of West street, a 15 inch drain carries any drainage to the pump well at Eliot and Tremont streets.



Map of the Boston Subway for the West End Trolley Cars.

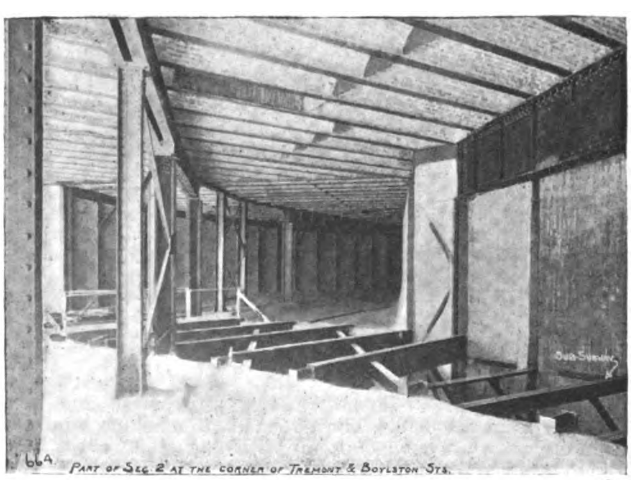
A masonry ventilating chamber has been constructed near the old burying ground in the Common and is supplied with a 7-foot fan, to be driven by a 500 volt General Electric motor. A similar but larger chamber is located in the west side of the four-track subway, a little south of West street, in which is installed an 8-foot fan to be belted to another 500 volt General Electric motor.

Section II.—This section practically consists of the Boylston station and approaches. It also includes a two-track subway of about 210 feet in length under the Boylston street Mall, connecting the two-track portion of Section 1 with the above station. The station section proper is 634 feet in length and connects at its northerly end with the four-track portion of Section 1, under the Tremont street mall. The station consists of four tracks and two island platforms, each about 30 feet wide. The platform nearest Boylston street and on the east side of the subway is for the north bound passengers and is about 340 feet in length, and that opposite Mason street and on the west side of the subway is for south bound passengers and is about 230 feet in length. The two platforms are connected by a sub passageway, 6 feet wide with a short flight of stairs at either end. Four wide stairways are provided leading to the surface of the Tremont street mall, two to each platform. The outward bound Tremont street track descends from the southerly end of the southward bound platform by an 8 per cent. grade, and round a necessary curve, passes easterly under the two Boylston street tracks, and then ascends a 4½ per cent. grade to its proper level. Numerous sidewalk lights are provided in the roof to help to light the station.

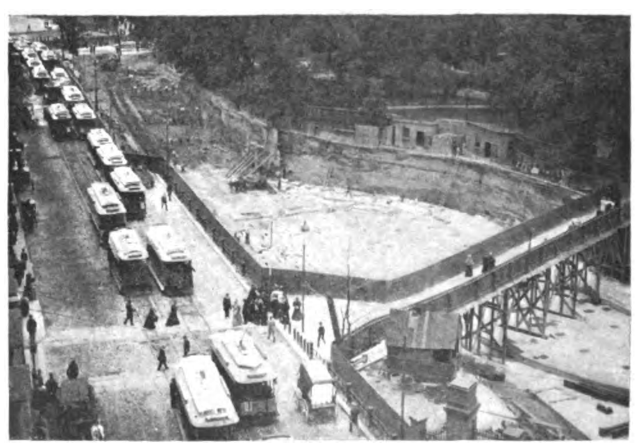
The same general design of construction of steel and concrete and masonry is followed as in Section 1. The concrete filling for the top of the arches is sloped from the middle to each side, to shed the water, and the roof and sidewalls are coated with asphalt mastic ½ inch to ¾ inch thick. Wherever the subway is less than 10 feet above mean low tide it is protected with hollow ribbed tiles coated with asphalt on each side. The whole of the drainage is conducted by stoneware pipes to the pump wells at Eliot street and in the Public Garden.

The Charles street pump well, near the Public Gardens, is provided with two 5 h. p. 500 volt motors, Gen. Elec. make, with automatic float control, and two No. 3 B. pumps, made by the Lawrence Machine Co., and at the Eliot street pump well are installed one 5 h. p. similar motor, connected to one No. 3 B. pump, made by the Lawrence Machine Co., and one 10 h. p. motor connected to a No. 4 B. pump, also made by the Lawrence Machine Co.

One of the many difficulties met with in the work was the



Building Section 2: Corner of Tremont and Boylston Streets.



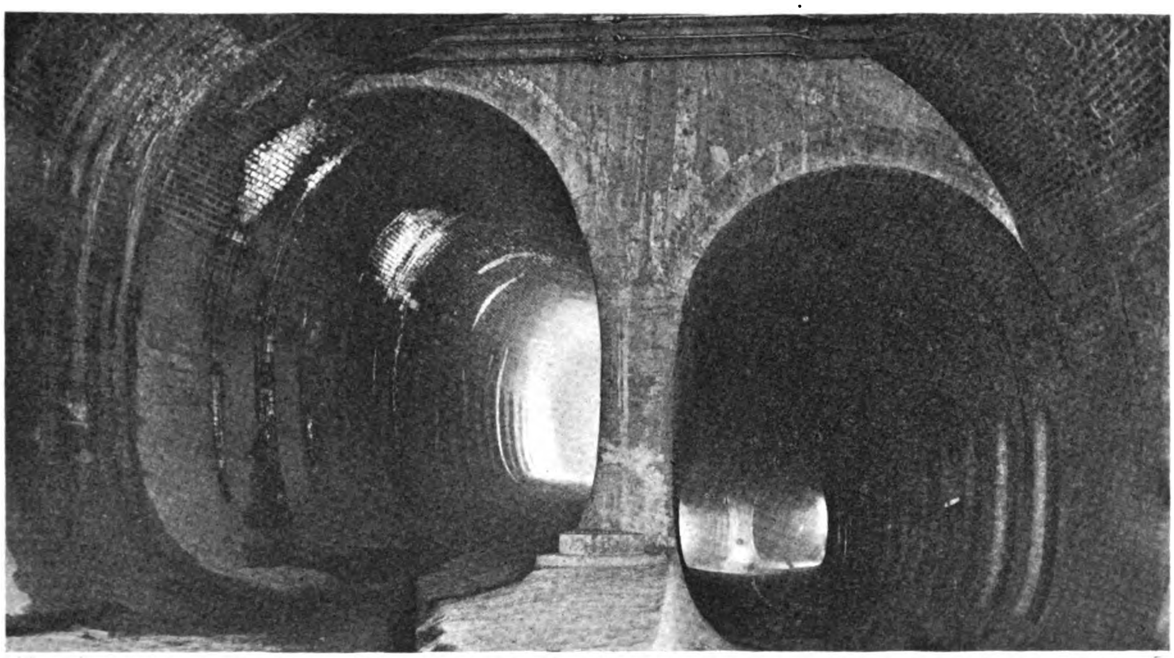
Preparing the Subway.—Looking Southerly on Tremont Street —Car Blockade.

crossing of two large water mains, 30 inches and 40 inches in diameter, respectively, diagonally across the line of the subway, a little south of Mason street. As these pipes were at a level below the roof of the subway and 15 or 16 feet above the invert, it was necessary to construct a syphon to pass down and under the invert and up again to the proper level. To provide for this in a proper manner, a concrete and brick conduit 10 feet in diameter was constructed in which the pipes could be laid and at the same time be accessible for repairs. The water mains are carried vertically downward at either end about 23 feet, and laid through this conduit. The conduit has built into it a series of steel bands or hoops, 2 inches wide and ⅛ inch thick, to strengthen it in case of serious leaks from the water mains. Special construction of "I" beams and brickwork is provided wherever the subway columns are near or resting on the conduit. A chamber, 10 feet by 18 feet, is provided at each end of the conduit for ready access for repairs. Two ⅛ bends are used to change the direction of the pipes from vertical to horizontal and vice versa. The upper elbows are trussed by steel harness connected to "I" beams anchored in the concrete.

Section 3.—This section consists of a four-track subway, about 300 feet in length, from the four-track portion of Section 1, north of the Boylston street station and the Park street station, or as it is more generally called the "Park street loop." The station consists of two island platforms, the easterly one, about 250 feet in length, being for the north bound, and the westerly, about 275 feet long, for the south bound, traffic. These platforms are irregular in shape, their greatest width being about 40 feet. Each platform is connected with the street by two independent stairways. The loops are provided so that cars on routes terminating at Park street can be sent on their return journey without switching and its attendant delays. Proper side tracks for holding extra cars or cripples are provided inside the loops, together with suitable pits under the tracks for inspection of motors and temporary repairs. The construction of the four-track portion is similar to that of Section 1, and that of the Park street station is practically the same as for the Boylston station. At the northern end of the station the two outside tracks, after passing around the loop, converge into two separate single track subways (Section 3½), which join Section 6 in the bell mouth opposite the Park Street Church. In connection with the construction of Section 3 the historic soil of Boston Common was trespassed on by the cars of the West End Street Railway Co., while the easterly portion of the station was being completed.

Section 3½.—This section, consisting of two short portions of single track work, was constructed at the same time the extensive changes in the sewers adjacent to Park street were made, hence the necessity for treating these as a separate section.

Section 4.—This section connects the Boylston station with the station at the junction of Shawmut avenue and Tremont street. It consists of two separate single track subways, one for the south bound cars at a lower level, 39 feet below the street at Boylston street, that for the north bound cars being only 23 feet below the surface. These two subways converge into a double barrel subway opposite the new Hotel Touraine, both being brought to the same level before reaching Eliot street, where the two tracks are carried in a wide single arch subway, and near Hollis street the westerly track is depressed and branches into another double bell mouth, one side for the south bound Tremont street cars and the other for the south bound Shawmut avenue cars, while the easterly barrel rises until it crosses over the south bound Shawmut avenue subway to carry the north bound Tremont street cars without a grade crossing. This portion of the work represents considerable engineering skill and thought, and the result is highly gratifying. From Boylston street to Common street this section consists of concrete sides and floors with brick arches filled in with concrete for the roof. In the wide arch subway, iron tie rods, 1¾ inches thick, are placed two feet apart to protect the brick arch from spreading. Refuge niches are provided every 6 feet. Vertical "I" beams are imbedded in the concrete in the two track subway to strengthen it, and these, like the rest of the iron work, are connected with tinned copper wires, and proper provision is made to guard against electrolysis. The rest of this section, southerly, consists of side walls of steel posts and concrete, with iron roof girders and brick and concrete arches. In order to interfere as little as possible with the daily traffic on the streets, this portion of the work was carried out by the slice method, as it is called, or in other words, short lengths at intervals, were opened up and constructed and ultimately joined together by the completion of the intervening slices. This also considerably lessened the chances of damage to adjacent buildings, etc.



SECTION 4.—HIGH AND LOW LEVEL TUNNELS CROSSING.

Section 5.—This section consists of the two 2-track inclines at the junction of Shawmut avenue and Tremont street, and the short length of four-track subway connecting these inclines with the southerly end of Section 4. The triangle enclosed by the two inclines will be arranged so that it can be used as a station with a wide platform between the two inclines, and two narrower ones on the outer side of each incline. This station will also be adapted for building over it a fireproof structure of several stories in height which can be used for an apartment block. This triangle was covered with old buildings which were removed under contract by Messrs. Elston & Sons, early in May of last year.

The remainder of the subway, most of which is completed but not yet open for traffic, comprises Sections 6, 7, 8, 8½, 9 and 10, with the necessary stations at Scollay, Adams and Haymarket squares.

ELECTRIC CONDUITS.—Considerable work in removing and replacing, or relocating the electric conduits had to be carried out besides the various changes in the water and sewer pipes, in many cases special provisions having to be made to

accommodate them. The following gives the number of lineal feet of duct which was relocated in Section 2, 3 and 4:

	Removed, feet.	Laid, feet.
Edison Illuminating Company:		
Section 2.—2½ inch duct	277	273
" 3.—2½ inch duct	52	52
" 4.—2½ inch duct	91.5	92.5
" 4.—3 inch duct	168	170.5
Boston Electric Light Company:		
Section 4.—3 inch temporary	...	591
" 4.—4 duct conduit	404	...
" 4.—2 duct conduit	87	...
New England Telephone & Telegraph Co.:		
Section 4.—3 inch temporary	...	146
" 4.—3 duct conduit	146	...
" 4.—2 duct conduit	45	...
Totals	2,906.5	1,415

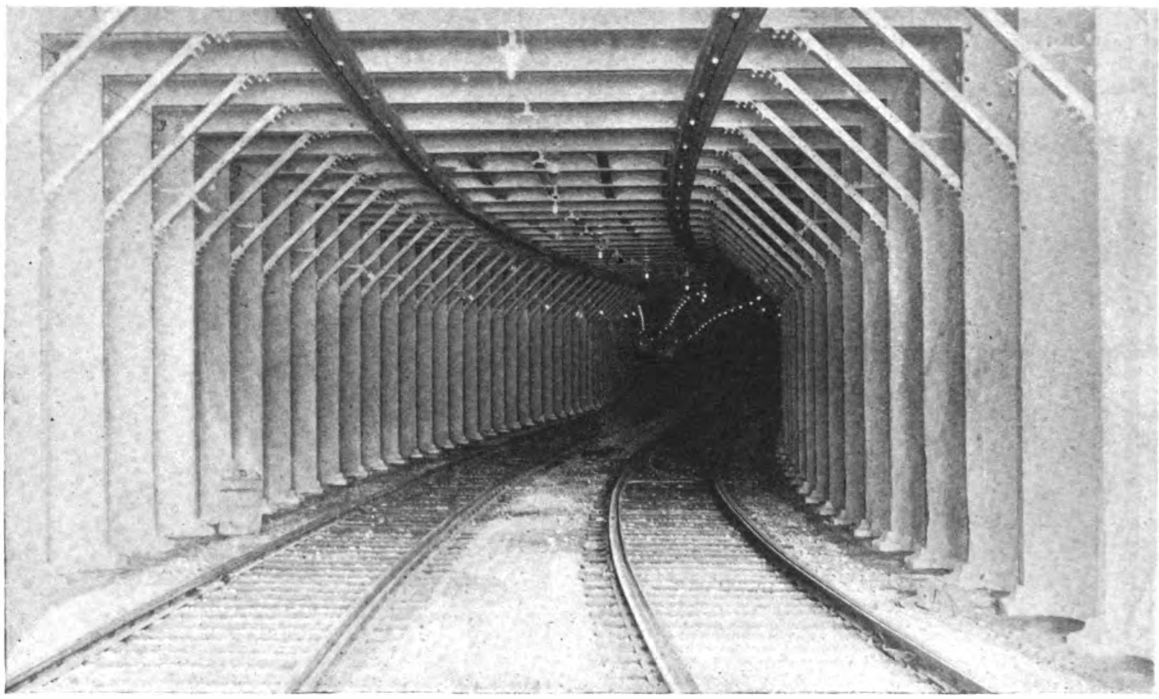
Much of the work necessitated by the construction of the subway, but not a part of the subway proper, while very interesting, containing so many and varied problems, each of which had to be taken up and decided on its own individual requirements, hardly falls within the scope of this article, but the underpinning of high buildings, the raising of large water mains, changing the location of sewers and electrical conduits, and even the lifting and transplanting of living forest trees, were undertaken and carried out with success.

The contractors for the steelwork and construction on the various sections are as follows:

Section.	Steelwork.	Construction.
1	Penn. Steel Company	Jones & Meehan.
2	" " "	E. W. Everson.
3	" " "	F. E. Shaw.
3¼	Boston Bridge Works.	
4	N. J. Steel and Iron Co.	Metropolitan Construction Co.
5	Boston Bridge Works	Wm. H. Keyes.
6	Berlin Iron Bridge Co.	R. A. Malone.
7	Carnegie Steel Co.	Shailer & Schniglau.
8, 8¼	A. & P. Roberts Co. Pencoyd Iron Works	Metropolitan Construction Co.
9	" " "	Richardson & Young.
10	Carnegie Steel Co.	Shailer & Schniglau.

THE TRACK.—The track is laid with tee rails, Am. S. C. E. standard, weighing 85 pounds to the yard, with continuous joints. Each rail is protected for its entire length by a guard rail of special section weighing 45 pounds to the yard, being bolted to it. The rails are spiked to oak ties which have been thoroughly treated with "Woodaline," to shed moisture and thereby ensure their proper insulation, and increase their durability. The ties are laid on broken stone and carefully ballasted with it. Each rail joint is connected with two 4-0 copper bonds, and every 500 feet all the tracks are properly bonded together and cross connected, and returned to the station by 500,000 c. m. cables. If found necessary a separate return to the power station will be established for any leakage current that may be collected from the ironwork of the subway, in order to prevent electrolysis.

OVERHEAD WORK.—A suitable inverted wooden trough is securely fastened to the ironwork of the roof and insulated with sheet rubber. Car barn hangers are set in flush into this trough and insulated with sheet rubber between the hanger and the trough. An insulating bolt of the Anderson pattern, and carrying a special mechanical clip designed by the engineers of the West End Company, supports the trolley wire, which is of special "figure of 8" shape, section having an area of about 360,000 c. m. These hangers are placed 12 feet apart on straight track, and 6 feet apart on curves. This construction is at once very rigid, simple, and workmanlike, and almost entirely eliminates the arcing of the trolley, so noticeable on the Nantasket Beach line, where the "figure of 8" wire is used, but suspended differently. The current is taken temporarily from the present underground feeder system of the West End Railway Company, but in the near future a new conduit with 500,000 c. m. cables will be laid direct to the central power station for supplying power to the subway alone. The whole of this portion of the subway from the entrance to the Park street loop is controlled from one section box, but any one track can be cut out at will, when necessary.



Boston Subway: Method of Illumination and Trolley Suspension.

LIGHTING SYSTEM.—The subway is lighted throughout by electricity, both incandescent and arc lamps being used. There are, in the opened portion of the subway, 600 incandescent lamps of the Bryan-Marsh make, and fifty-five enclosed arcs, some of them of the well known "Manhattan" make, and some supplied by the General Electric Company. Besides these there are 20 direct current high tension arcs, supplied by the Boston Electric Light Company. The incandescent lamps are run in lines on either side of the subway and also between the tracks. The lamps are placed about 36 feet apart on the lines, and the line circuits are alternated so as to properly distribute the lamps. The regular railway circuit is used, but the power for one of the circuits or lines is supplied from the Dorchester power station, and that for the other lines from the Central power station. The lamps are run 5 in series.

The enclosed arcs are used for lighting the subway stations, and are run from the same power stations, and are also 5 in series.

There are also 20 direct current arcs, in the stations, run from the lines of the Boston Electric Light Company. These will probably be operated for 12 hours per day, and will al-

ways insure light in the stations in case of any blowouts in the railway power stations.

The switchboard for all the lighting of this portion of the subway is placed in a large room, beneath the junction of Boylston and Tremont streets, and consists of three black marbleized slate panels installed by the General Electric Company fitted with three of their type of automatic circuit breakers of a capacity of 500 amperes each. One of these is connected to the 500 volt incandescent circuit of the Boston Electric Light Company, one to the Dorchester power station, and one to the Central Power Station. The switchboard is also supplied with three round pattern Weston ammeters, and with six double-pole double-throw switches, which can be used in emergency to throw all the incandescent lamps on to the service of the Boston Electric Light Company, although all these will ordinarily be run from the West End Company's power station.

The power can also be taken entirely from the Dorchester or the Central Power Station at any time by the opening and closing of the switches.

In the rear of the switchboard is a feeder board having 22 quick-break, knife-blade switches, together with porcelain cut-outs, which handle the various circuits, and putting the entire control of the lighting of the subway South of Park street in the care of the operator at this switchboard.

There is also a system of electric block signalling in process of installation to guard against accidents to cars standing in the Boylston street station. This is more or less an experiment, but if successful, it will be operated permanently.

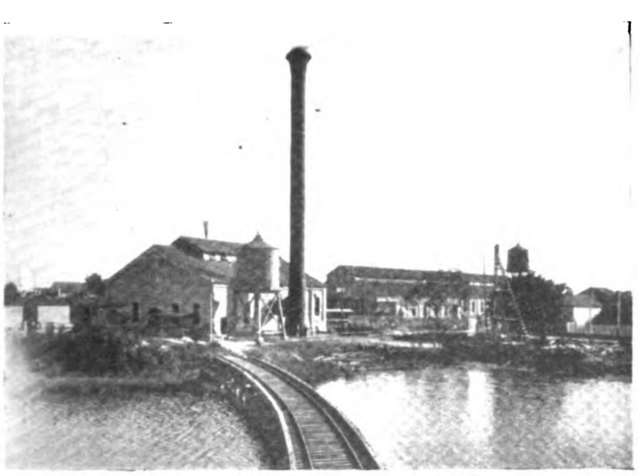
Electric heaters are located in the ticket offices, but the stations are not heated at present, as it is expected the temperature will not fall low enough to require it, even in the coldest weather.

The electrical and track work has been laid out and installed by the West End Street Railway Company under the direction of Mr. C. F. Baker, their able master mechanic.

In conclusion the writer wishes to express his thanks to Chief Engineer Howard A. Carson for his courtesy and permission to inspect the works from time to time, and also to Mr. G. P. Goodman, his photographic assistant, for his valuable help.

THE POWER HOUSE AND CAR BARN OF THE CHARLESTON CITY RAILWAY COMPANY, CHARLESTON, SOUTH CAROLINA.

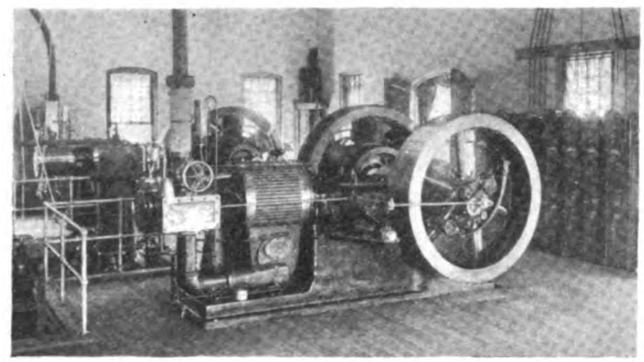
ONE of the latest of the larger cities in the South to adopt electric traction has been Charleston, S. C., but in this respect that much-tried city has been very fortunate, as it is certainly benefitting by all the latest experience and study of the subject. The service that it now enjoys will compare most favorably with that in any part of the Union, and the instant popularity of it has proved that it meets a demand of the most pronounced character. The Charleston City Railway Company, owned now by New York capitalists, absorbed the



Power House and Car Barn, Charleston, S. C., City Railway.

other roads in the city, so that the public has the advantage of a strong management and of the best facilities for local inter-communications, due to the reforms rendered necessary in changing over from a slow and intermittent mule service to a rapid, frequent electrical system. The whole work, both of a consulting and of a contracting character, has been done by the firm of J. G. White Co., New York City, in whose hands every detail has received as usual the most thorough care and attention, as will be seen from the accompanying data and illustrations:

CAR HOUSE.—The car house is located on a lot 184 feet by 312 feet, at the corner of Meeting and Pointset streets. It is built of brick and its outside dimensions are 255 feet 3 inches by 67 feet 8 inches. An office building 71 feet 4 inches by 17 feet 4 inches is built alongside the car house. The distance from top of rails to under side of roof trusses is 18 feet. The



Ball & Wood Engines, Direct Connected, Charleston, S. C., Railway Plant.

car room is 209 feet 4 inches by 65 feet, and there are armature and store rooms and a repair shop at the rear end of the building. The main car room contains three pits, each 100 feet long, and the repair shop contains two pits 26 feet long. The elevation of the floor of the car barn is 11.5 feet above low tide.

On excavating for the foundations, water was encountered a few feet below the surface, and the ground was found to be a fine sand, mixed with loam, and of very little supporting power. To avoid piling, the foundations were not carried more than 2½ feet to 3 feet below the surface.

Test pits, excavated to a depth of six feet, led to the conclusion that shallow foundations would be likely to cause less trouble from settlement than deep ones.

Under all the exterior walls there was laid a footing of Portland cement concrete 3 feet 4 inches wide and 2 feet thick. On this concrete footing the brick footings were laid and the structure was completed in the usual manner—no other precautions being taken to prevent settlement or cracking of walls.

Below the ground line, all the brick work was laid in cement mortar, and above the ground line in lime mortar.

All the interior partition walls are brick and rest upon concrete footings, similar to those under exterior walls. The walls of the pits are brick, laid in cement mortar, and all pits have concrete bottoms.

The floor of the car room and the floor of the paint shop are concrete, with a finishing coat of Portland cement mortar, troweled smooth and flush with the tops of the rails. All exterior walls are 12 inches thick in panels, and are 20 inches thick at pilasters. The roof trusses are steel, and the roof covering is No. 20 corrugated iron. A monitor 27 feet wide extends the whole length of the building, and all sashes are arranged to be opened and closed from the floor.

The interior walls are kalsomined, and the trusses and under side of corrugated covering are painted a light color.

The car house contains five tracks, 11 feet 6 inches apart center to center, and the center of one side track is 12 feet from side wall of building to allow room for convenient handling of repair parts and to form a passage way to the rear of the car room.

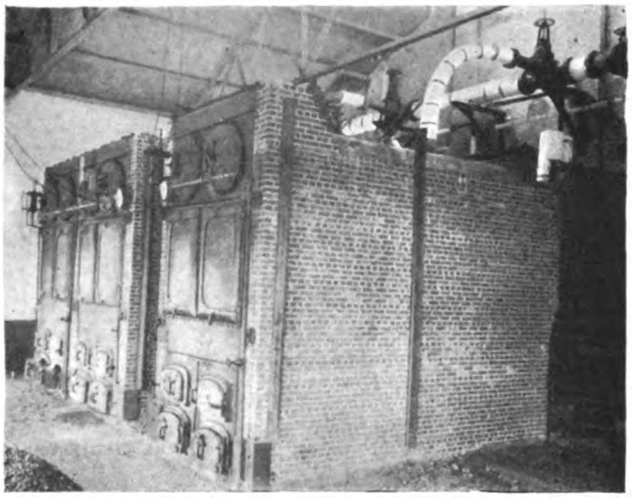
The office building contains superintendent's office, conductors' and locker room, and shower baths. Basins and shower baths have been liberally provided for the purpose of encouraging personal cleanliness on the part of the employés.

POWER HOUSE.—This is located on a lot 300 feet by 355 feet, fronting on Meeting street, and extending from Centre street to Coolblow street. This lot is directly opposite the lot on which the car house is built, and about half the lot is under water.

In designing the power plant the object aimed at was to secure a thoroughly substantial and reliable plant, with the least possible expenditure of money. The building is a plain, substantial, brick structure, designed for the sole purpose of housing the machinery.

The power house is 85 feet by 68 feet 4 inches, and contains

a boiler room 45 feet by 65 feet and an engine room 36 feet by 65 feet. The exterior walls are brick, 16 inches in panels, and 20 inches thick in pilasters. The foundations and concrete footings are similar to those of the car house. The partition wall between the boiler and engine rooms is brick, 12 inches thick, with pilasters 16 inches thick. The clear height between floor of boiler room and under side of roof trusses is 22 feet. The engine room floor is 4 feet 6 inches above the boiler room floor. The roof trusses are steel, and the roof covering is No. 20 corrugated iron. The roof is continuous over



BABCOCK & WILCOX BOILERS, CHARLESTON POWER HOUSE.

both the engine and the boiler rooms, and a monitor 27 feet wide extends nearly the entire length of the building.

The floor of the engine room is constructed of 10 inch by 12 inch joists on brick piers; the under floor is 4 inch thick plank, and the top floor is 1 inch maple. The floor of the boiler room is brick, laid on edge on a 4 inch thick bed of concrete and grouted flush.

All interior walls are rubbed smooth and kalsomined in a light color. That part of the roof over the engine room is ceiled with hard pine, nailed to spiking pieces, which are bolted to the steel purlins, and the ceiling is finished in hard oil finish.

The boiler room contains two 200 h. p. Babcock & Wilcox boilers, set in one battery, and one 200 h. p. B. & W. boiler, in a separate setting. Provision has been made for two 300 h. p. B. & W. boilers, which will be installed later. There are two Deane 7½ inch by 4½ inch by 10 inch duplex boiler feed pumps, and one 7½ inch by 6 inch by 10 inch duplex tank pump. The engine room contains two Ball & Wood 14 inch by 27 inch by 16 inch tandem compound condensing engines, and two direct connected 200 k. w. G. E. generators, running at 200 revolutions. The foundations for the engines are carried on piles, about three feet apart and "driven to refusal." Piles were also driven for foundations for a 500 h. p. engine to be installed later. The heads of the piles under each engine are encased in a bed of Portland cement concrete, 3 feet thick, and forming footings on which to commence the brick foundations proper. The footings for the partition wall between engine and boiler room are carried about 8 feet below the floor of the boiler room, and form one wall oof the condenser pit in the engine room.

STEAM DETAILS.—The walls of the condenser pit are brick, laid in Portland cement mortar, and the bottom is Portland cement concrete 18 inches thick. Owing to the bottom of the condenser pit being level with high tide, and at least three feet below the ground water level, it was necessary to construct it water tight and to provide a steam ejector for removing any water which might escape from the pumps and condenser.

The walls of the pit are independent of engine foundations. The condenser is a 14 inch by 22 inch by 24 inch horizontal single Deane jet condenser. The boilers, piping, engines and auxiliaries were designed to be operated under 175 pounds steam pressure. All piping is full weight standard pipe, or extra heavy, and all steam fittings, larger than 2½ inch, are gun iron, having a tensile strength of not less than 29,000 pounds.

Stratton separators are used on the steam pipes to the engines, not so much to take care of condensation as for protection against possible priming due to bad water.

There is one 600 h. p. vertical Goubert feed water heater in the condenser pit, and the exhaust piping from the engine is arranged so that the exhaust may be passed through the primary heater and condenser, or through the primary heater to the atmospheric exhaust, or directly to the condenser, or directly to the atmospheric exhaust.

The injection water inlet to the condenser is 19 feet above the supply. A 4 inch priming pipe connects with the general water supply system, and enables the condenser to be readily started.

A bridge spans the condenser pit at the point at which the valves in the injection, priming and steam pipes are located. The steam supply to the condenser is led around so that all the valves controlling the operation of the condenser are located within easy reach of the operator when standing on the bridge referred to. A valve is also placed in the steam pipe close to the condenser, so that its operation may be controlled from the floor of the pit.

The exhausts from the condenser, and from all pumps, discharge into an auxiliary exhaust pipe which connects with a 600 h. p. vertical Goubert supplementary heater, set in boiler room, and with the atmospheric exhaust. The main atmospheric exhaust pipe is 14 inches in diameter, and extends above the roof of the power house, where it terminates in a condenser head. The valves are all of the Chapman make.

All drips from the high pressure steam system are led to a Deane receiver and Duplex plunger pump, which automatically returns to the boilers the water of condensation. The feed water piping is 3 inch extra heavy and is arranged to pass the feed water through the primary and supplementary heaters, or through either of them, or directly to the boilers. Owing to the fact that the best feed water obtainable contains a large amount of salt and scale forming impurities, provision has been made for installing a feed water purifier later, if it should be found necessary to do so. In the engine room there is a gauge board, having steam and vacuum, needle and recording gauges.

There is a steel chimney 125 feet high and 7 feet diameter at top, erected on one side of boiler room, about five feet from building, and a plate iron breeching connects the boiler settings with the chimney. The main damper in the breeching is controlled by a Spencer automatic damper regulator, placed in the engine room. The steel chimney is lined throughout and the flaring bottom section is filled in solidly to increase stability. The chimney foundation consists of piles, capped with a bed of concrete, 21 feet square, supporting the brick base as shown. The chimney was built E. Keeler & Son.

A 30,000 gallon wooden tank erected on a wooden tower, 20 feet high, alongside the power house, supplies feed water for the boilers. A 30,000 gallon wooden tank, erected on a steel tower 39 feet high, alongside the car house, furnishes water supply for car washing and fire protection; 2½ inch hose valves are located in the car house and in the power house. The discharges from the three pumps in the boiler room are so arranged that any one, or all of the pumps, can be used to feed

TRACK CONSTRUCTION, BROAD AND MEETING STREETS, LOOKING NORTHEAST, CHARLESTON, S. C.

boilers, or to pump into either of the tanks and in the fire protection system of piping. The tank on the 39-foot tower alongside the car house is supplied through the general fire protection system of piping. The 6 inch rising pipe connects directly with the bottom of the tank alongside the car house. The 2½ inch general supply passes through the bottom

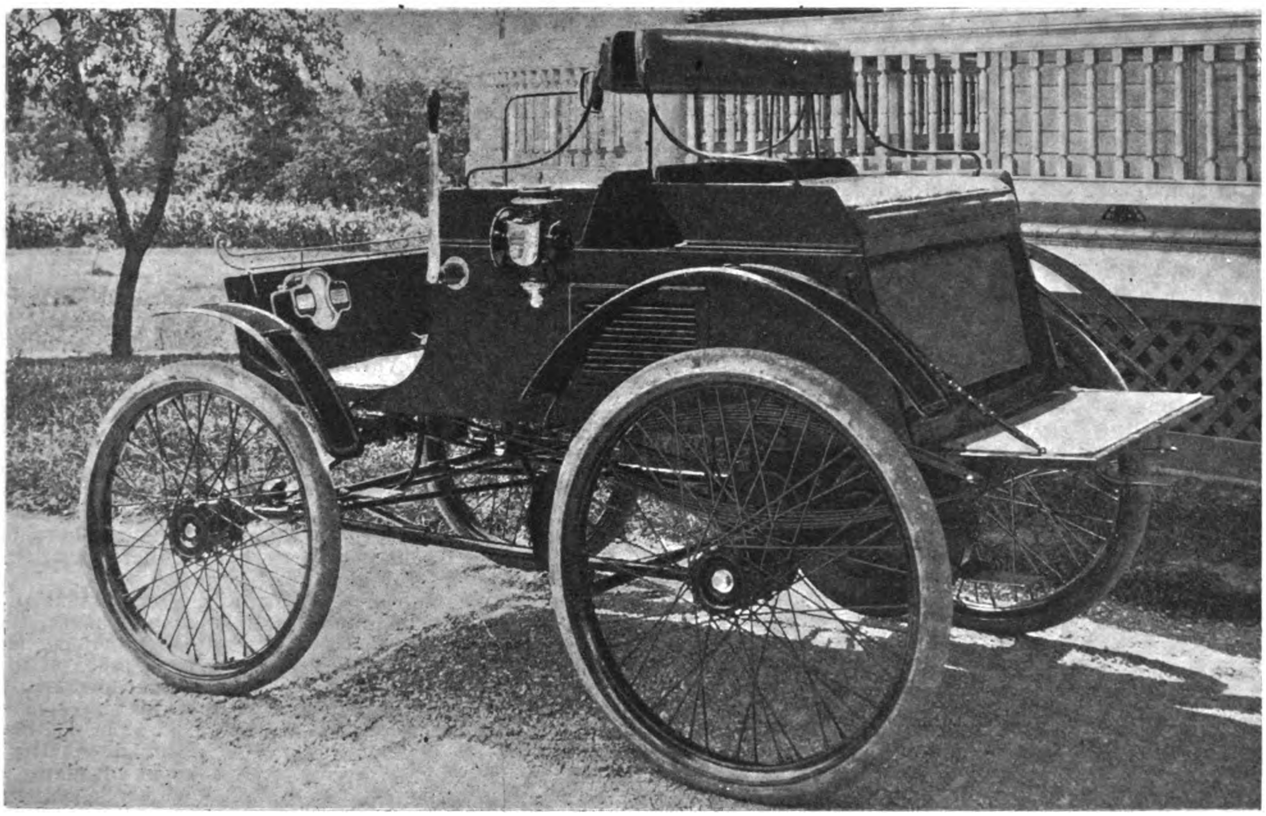
and terminates about eight feet above the bottom of this tank. This 2½ inch general supply furnishes water for car washing and other purposes, and the object in carrying it 8 feet above the bottom of the tank was to prevent the possibility of the tank being emptied through this pipe, leaving no water for use in case of fire. In order to obtain for fire purposes a head of water due to a 100-foot tank tower, and at the same time save the difference in cost between a tank on a 100-foot tower and one on a 39-foot tower, a special arrangement of piping was devised. With all hose valves closed the pumps deliver into the fire protection system of piping until the pressure reaches 50 pounds, at which pressure the automatic relief valve opens and the water passes through it and into the tank, through the 6 inch rising pipe. In case of fire, occurring at a time when the pumps are not delivering into the fire protection system of piping, on opening any of the hose valves water would be supplied from the tank through the 6 inch horizontal swinging check valve until the pumps were started and delivered more water than could be discharged through hose, when the horizontal swinging check will close and the pressure rise to 50 pounds, and the surplus water pass through the relief valve to the tank. In case of an accident to the pumps during a fire, the horizontal swinging check valve would render all the water in the tank available, but under reduced pressure. Each hose valve is provided with 100 feet of 2½ inch hose, and 1 inch nozzle, with the exception of the two hose valves in the engine room. The two hose valves in the engine room turn down and discharge directly on the floor. A base about 4 inches high has been constructed around the condenser pit to support a railing, and to act as a dam in case it should be necessary to flood the floor of the eingine room on account of fire. The floor of the engine room being the only combustible part, provision was made for flooding it and hose excluded.

MAIL BOXES ON STREET CARS.

The Postoffice Department has received a report from Des Moines, Iowa, where an experiment is being tried of having letter boxes attached to all the street cars and a large share of mail collection taken up by them. The cars in Des Moines all run past the postoffice. They stop at all places to receive a letter or other mail matter and, as they come by the postoffice, a carrier takes the mail from the boxes. During July there were collected by this means 29,237 letters, 6,059 cards and 441 pieces of second, third and fourth class mail matter. It shows an increase of 1,300 pieces over June, and the postmaster thinks that, as many cars were open and no boxes attached, not so much was collected by this means as if all the cars were closed. If the experiment be successful, it will be tried in other cities.

NEW RIKER ELECTRIC CARRIAGE.

MR. A. L. RIKER, of the Riker Electric Motor Company, Brooklyn, has brought out a new and interesting type of his electric carriage, which is illustrated in the accompanying engraving. As will be seen, it is a four-wheel, four-seated vehicle, with low front dashboard, and with seats back to back across the carriage. The weight complete is 1,800 pounds only. The wheels are 32 inches in front and 36 inches rear, fitted with 3-inch pneumatic tires. The body is black and the running gear dark green with red stripes. There is one Riker motor, normal 2 k. w. capacity, weight 142 pounds, driving upon the rear axle, 1,000 revolutions per minute, and making single reduction at a ratio of 9 to 1. The motor and gear case are entirely enclosed, being waterproof and dust proof. The axle is double, the motor being fixed upon the outer stationary axle or sleeve. The batteries are of the zinc-lead type, of special design, and weigh 760 pounds, there being 36 cells, each 7 inches long, 3½ inches wide and 9 inches high. They give 150 ampere hours at the 10-hour rate of discharge and 120 at the 4-hour rate. They are apparently both cheap and durable, and Mr. Riker expects a great deal from them.



RIKER'S NEW ELECTRIC "STANHOPE."

The steering is done by the vertical handle seen in front, which has so light a movement that finger pressure will govern it. It applies by toggle joints to the wheels of the front axle and makes an extremely neat and quick turn with the wheels, independently of the position of the carriage body. The controller is the lever seen on the left of the carriage. It works backward and forward, and the direction of its travel corresponds with that of the carriage. There are three regular speeds, and the carriage can, if necessary, be run as high as 25 miles an hour. On the dashboard in front of the driver, is a combination testing instrument, reading for both volts and amperes, and so legible that the driver can easily see the indications from his seat. This instrument has been specally built by the Weston Electrical Instrument Co. The carriage has also an electric bell, headlight and two side

lights. It operates very smoothly, and Mr. Riker says he has endeavored to free it from conventional lines, so that the driver or passenger would never know from looking at it, that such an animal as the horse was once in existence. The charging connections are under the flap of the rear seat, and the rheostat enables the carriage to be charged on any straight, multiple circuit it is likely to find available anywhere, from 80 volts to 500. A number of these handsome carriages have already been ordered, and Mr. Riker thinks that their price does much to bring the horseless vehicle within the reach of every-day users. He is also building delivery wagons on the same general lines.

EDUCATIONAL BONDS.

BY PROF W. M. STINE.

IN The Electrical Engineer for July 29 there appeared an editorial, "Colleges in Poverty," which was full of suggestion. It presented a problem which is yearly growing more apparent. The past two decades have been pre-eminently distinguished by the number and amounts of endowments for founding or enlarging institutions of higher literary and professional training. Of the most notable gifts, scarcely one has escaped more or less serious financial depreciation and loss; and it is apparently an easier task to secure a large endowment than it is to invest it advantageously and permanently.

Several years since President Thwing pointed out several pertinent facts relating to the investment of college funds. The college funds of the country are invested with more uniform success than those of other corporate bodies. They call to their aid the best financial judgment and experience of many of the ablest commercial advisers.

"The college," he states, "has no right to run financial risks," yet as he reviews the financial status of our colleges, it is all too apparent that risks are often assumed with consequent losses. In spite of the wisest counsels, mistakes in investment are frequent. Men who have accumulated large fortunes and have been benefactors of their time by founding and endowing colleges, have been confronted by a new financial consideration, the permanence of investment.

Briefly, the investment of funds for a college presents an aspect differing greatly from the usual business procedure. The investment must be conservative and permanent, and not changed with fluctuating markets. Colleges are not able to carry large reserve funds, and severely feel the loss when any part of them becomes unproductive. Of the half-dozen or so great institutions founded in recent years for the promotion of higher culture and the technical study of the sciences, all, with one exception, have suffered more or less financial losses through depreciated investments. In some cases this has occurred through the mistaken judgment of the donors, who, with the conservative grasp of large wealth, have been unwilling to donate funds unreservedly to a constituted board of trustees, preferring rather to retain the investment in their own hands. Confronted by conditions and problems radically different from those encountered in the usual routine of business, it is not surprising that they have erred in judgment and that their institutions have suffered.

The failures of the endowments invested in two great railway systems have been conspicuous. At the time such investments were made, railway bonds were justly considered stable and satisfactory. But times have changed; competition and the retribution of dishonest financiering have brought disaster and railway holdings are no longer profitable.

The depreciation of real estate values, litigation in the settlement of estates, have each added their share to the general distress. Much of the distress of the afflicted institutions has never reached the public; only those in college circles know the severity of the ordeal.

The relation of these colleges to the public at large is generously appreciated. The rapid growth of our country in its material and intellectual development depends largely upon such institutions for its existence and increase. Probably it will not be disputed that the technical school is one of the most potent factors in the material progress of to-day. In this broad view, each college and technical school is a factor in national progress, and is only sectional in a restricted sense.

What shall be the remedy for the present depressed financial outlook of our institutions of learning? Whatever form the remedy assumes, one of its features is in guaranteed investment, so permanent in its nature that the donors of endowments shall be assured that their gifts will be safe, whatever the conditions of the railways and real estate markets, and that widespread panic conditions will not affect them. A college must be permanent before it can acquire the services of distinguished and able professors. It is essential that departmental incomes shall be so fixed and assured that plans for development may be far-reaching. It is a debt owed young men and women that the courses of study, covering often seven and eight years, shall not be broken in upon and curtailed by financial fluctuations of the funds.

The proper education of the youth of the country being a matter of such national concern, it would be only just, in spite of our well known aversion to paternalism, that the permanence needed be in some way assured by the general government. The obligation would be met by the issuance of some form of educational government bonds. Such bonds might be of the usual denominations, and bear interest of at least 4 per cent., the rate of interest to be perpetual. The bonds should be sold directly to the purchaser at face value, and be redeemable but not transferable. This may be regarded as equivalent to the purchase of a taxation support from the government, but if it be such, wherein is the objection to it? In practice a serious obstacle might arise from the extent of the application, all organized charities claiming the same permanent protection. But the wheels of progress have been too often stayed by such reasoning.

These bonds would doubtless result in a great increase in the endowments of the colleges. Many persons of limited means would prefer to leave moneys for such purposes could they be assured of the permanence of the bequest, and that the individual gift would not be quickly absorbed in the general fund for running expenses. Men who, all through their careers, have felt the lack of such training, would respond more generously. Various other advantages readily suggest themselves.

There may be some fear that such procedure would result in a gigantic protected monopoly for the colleges, and that they would become excessively wealthy. This is certainly not the present condition of affairs, for the aggregate value of the real estate and endowments of the colleges is a less sum than the aggregate investments in electrical street railways alone. It is further a question if institutions should not possess large incomes, so large, indeed, that education should incur no fees of any kind whatever.

Aside from the enormous expenses of equipment of laboratories and their maintenance, more, much more, money is needed for scholarships, to develop the promising men and women who throng our colleges, and save much of the priceless energy which is now so lavishly expended in the mere struggles for existence. If it be thought that some of our laboratories cost excessive sums of money, in contrast there is not a laboratory in this or any foreign country whose equipment has cost the sum yearly spent by many wealthy individuals in the maintenance of a summer home, or a magnificent yacht.

THE ELECTRICAL LABORATORY OF THE UNIVERSITY OF WISCONSIN.

RECOGNIZING a fully equipped laboratory as one of the essential features of technical training, the University of Wisconsin has been continually adding to the equipment of the electrical laboratory, and, in addition to appropriations made each year for the purpose, the collection of machines and electrical supplies has been materially increased by donations of various electrical manufacturers who find it to their interests to have their products represented.

The collection of dynamos and motors has been made with the view of obtaining a large variety of machines rather than large machines, with the purpose of enabling the student to become familiar with any type of dynamo or motor which he is likely to meet in practice. Among the machines installed are 12 direct current constant potential dynamos and motors of different types, ranging from 1 to 10 h. p. capacity, 4 railway motors, 3 arc machines of different types, alternating and direct current arc lamps, single and polyphase alternating current dynamos and alternating current motors of the three-phase, two-phase and self-starting synchronous types. Current from the monocyclic generator of the city lighting station is available for experimental work, as well as that from the 500 volt railway circuit. The various dynamos in the labo-

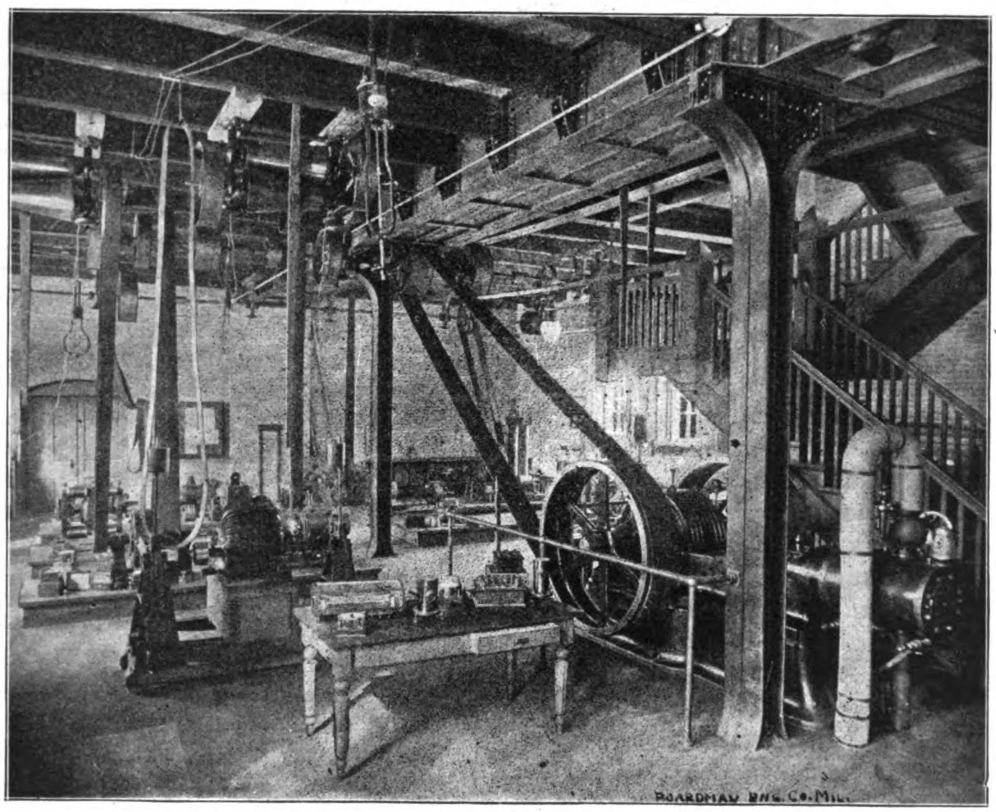
ratory are belted to overhead shafting and are run from a Weston engine, which regulates excellently for constant speed.

The bank of transformers represents the type of nearly every manufacturer in this country as well as that of several foreign makers. For measuring purposes, a number of wall ammeters and voltmeters are conveniently located, and the instrument shelves show portable ammeters, voltmeters and wattmeters of the Weston, Whitney and other types, a portable electrostatic voltmeter and a variety of other instruments which need not be enumerated. The recording wattmeters include a Thomson instrument for street car testing and a bank of recording wattmeters which are useful testing instruments, as well as offering an opportunity of studying their relative merits. The laboratory is well equipped for making measurements of the magnetic qualities of iron and steel, having a Ewing hysteresis curve tracer, a Ewing magnetic bridge and a Ewing hysteresis tester. A 1 h. p. 1,000 volt dynamo, together with galvanometers and accessories, serves for measuring the insulation resistance of wires, cables, etc.

A convenient method of absorbing power and of conveniently varying it at will is very necessary in such a laboratory, and after trying various liquid, iron and german silver rheostats, three lamp banks containing 100 incandescent lamps each, capable of absorbing 10 electrical h. p., were made, and are all that can be desired in the way of convenience. The fields and armatures of each machine, the wall instruments and the rheostats are connected by wires laid beneath the floor to a switchboard, enabling any combination of instruments and machines to be easily and quickly made.

A division of the electrical instruction which has recently been developed and for which suitable laboratory equipment has been installed, is that of electrochemistry and electrometallurgy. For the electro-deposition of metals, eight enameled iron tanks are used, with iron vats for hot water and lye, lead-lined tanks with running water, and grinding and polishing lathes for cleaning and polishing the metal surfaces. The current used for this work is supplied by a rotary transformer, transforming from 110 to 6 volts. Three electric furnaces of different types are used for experimental work with high temperatures and for the electrolysis of molten substances. The accompanying half-tone shows a portion of the dynamo laboratory, and the electrolytic laboratory is located on the second floor of the same building.

The experimental work in the laboratory is planned with the view of acquainting the student with the various types of electrical apparatus, use of electrical instruments, and special attention is given to familiarizing him with the most approved methods of commercial testing which are frequently used in practice.



DYNAMO LABORATORY, UNIVERSITY OF WISCONSIN.

ROENTGEN RAYS

MAGNETIC DEFLECTION OF CATHODE RAYS.

If the lines of force of a uniform magnetic field are at right angles to the rectilinear path of cathode rays, the rays are deflected in such a manner that their path assumes the shape of a circular arc, whose plane is normal to the direction of the lines of force. The extent of the deflection depends upon the field, and also upon a variety of other conditions, such as the degree of exhaustion, the chemical nature of the gas, the dimensions of the tube and the presence or absence of spark gaps. W. Kaufmann, in "Wiedemann's Annalen," claims to have proved that all these conditions are simply secondary, and may be reduced to the influence of the discharge potential between anode and cathode. He also proves that the deflection is inversely proportional to the square root of the difference of potential between the electrodes. The cathode rays were generated in a wide cylinder provided with a narrower tube containing the cathode at the end and the anode at the junction with the cylinder. Thus the shadow of the anode was thrown upon the other end of the cylinder, which consisted of plate glass with a thin layer of fluorescent chalk. The cylinder was surrounded by a coil of wire wound on a zinc cylinder, which produced a uniform field at right angles to the cathode rays. Separate series of measurements were made to determine the influence of the material of the cathode, the distance between the electrodes, the nature of the gas and the presence of spark gaps. In every case the curvature of the rays, divided by the square root of the difference of potential, was found to be constant within 1 per cent.

VOL. XXIV. NEW YORK, SEPTEMBER 2, 1897. No. 487

ELECTRICAL MACHINERY AND LABOR.

NO one who follows the course of events in the applications of electrical machinery and apparatus of all kinds can fail to recognize the important position which these appliances have already assumed in the economy of civilized communities and the still greater importance to which they are destined in the future. As many electrical appliances may be classed under what is known as labor-saving machinery, it seems opportune to inquire as to the probable effect of the increasing adoption of such machinery, upon the status of the so-called laboring man, or, better, the "wage-earner." In the light of the experience of the past one hundred years such an inquiry might appear to be unnecessary but when so representative a man as Bishop Potter of New York, as he recently did, lays at the door of the labor-saving device many of the bad social conditions and much of the discontent of the masses, it seems indeed worth while to cast a glance at the state of affairs. What, as a matter of fact, has been the effect upon labor, so called, of the labor-saving machine? For answer we must look to reliable statistics, and these are afforded in a brief, but admirable review of the question contained in the August Chautauquan, by the pen of the Hon. Carroll D. Wright, U. S. Commissioner of Labor. As a statistical analyst, Mr. Wright will be conceded to rank without a superior in the United States and the figures he brings to bear upon the subject prove conclusively, not only that labor-saving machinery does not deprive men of labor, but that it broadens the fields of their activity to a marked degree. Look in whatever direction we will, it is found that wherever machinery has gained its highest development, and greatest employment, there also are the greatest number of men at work. This statement alone, as Mr. Wright says truly, ought to be sufficient to answer society that the introduction of machinery has not deprived men of labor. Among the many specific examples cited by Mr. Wright, those relating to electrical branches will appeal particularly to our readers. Thus it is shown that thousands and thousands of people are employed in telegraphy where not a single individual has been displaced. These thousands find remunerative employment in the construction of telegraph lines, the manufacture of telegraph instruments, the operation of lines, etc. The telephone has added to this vast accumulation, while who can estimate the numbers that have been directly benefited since the introduction of the dynamo, the electric motor, the electric light and the electric car. Perhaps as good an example of the lesson he seeks to convey, and as good a contradiction to the common belief—if it really be common—as could be well found, is the experience cited by Mr. Wright during a visit to Minneapolis and St. Paul a couple of years ago. The electric line between these twin cities, by the superior facilities offered by it, caused the suspension of the steam road which had theretofore been in operation. Having been informed by a fellow-passenger, a mechanic, that the brakemen and other train hands of the old steam road had been thrown out of employment, he questioned his informant more closely and finally elicited the information that only six or eight people were practically injured by the new order of things, while it took eight or ten times the number of men to run the frequent electric cars. But what is more, a low grade man, says Mr. Wright, cannot run an electric car; he must have intelligence enough to understand and comprehend the methods necessary for the propulsion of the cars, and as an intelligent being he is vastly superior to the man required to drive the horses of an ordinary horse street car. So much for those who look upon machinery as soul-deadening and intellect-killing devices. Mr. Wright also proves conclusively that with the greater skill required to handle machinery come higher wages, and shorter working hours. He mig..t have gone further but he has brought enough facts to bear to disprove absolutely that lingering barbarism and misguided opinion that caused the mob of spinners to destroy Hargreave's newly-invented jenny. We have probably not heard the last of such folly, but the philosophy of history is so strong in its indications that error can now be little else than wilful.

WHERE THE TELEPHONE COMES IN.

ONE of the peculiar features of the telephone is that it takes intelligent people so long to find out the ease with which they can accomplish the purposes of business and pleasure when they resort to its use. To be bedridden is popularly supposed to be the height of seclusion and deprivation, but with the telephone the invalid and valetudinarian become the people who can enjoy more things that are going on than anybody else. It looks as though the bicycle had arrived just in time to preserve in pristine vigor and symmetry the legs of the human family; for the telegraph and telephone, supplemented by the horseless vehicle and the "thunderbolt express," had threatened to render legs as superfluous as the atrophied tail. The ability of the ubiquitous telephone is little short of supernatural. Down in Kansas, at Wichita, Superintendent W. E. Stanley, with a broken thigh, and, therefore, unable to leave his bed, has been telephonically conducting the largest Sunday-school in a State whose very heresies are Brobdignagian. Mr. Stanley, lying on his back, talked to the school, gave out the hymns, delivered a little address, listened to the singing, and expressed his delight; while in the evening the performance was reversed, and he took in the sermon of the Rev. Dr. Slutz. The injunction of the Great Healer, "Take up thy bed and walk" is abundantly amplified in the modern version of science, "Lie in thy bed and talk." Curiously enough from Kansas, where just now, happy to relate, they are learn-

ing a good many things they did not know last year, comes the statement that at Fort Scott, "for the first time," testimony has been received by telephone, in a case where two witnesses were absent. It is to be hoped that this practice, new to Kansas, but not new to other parts of the country, will spread and grow, and that juries as well as witnesses can be spared the tedium and annoyance of attendance in court. If there is one hollow sham and wretched nuisance to-day, it is that of giving and hearing evidence in the law court, and every honorable, sensible man abhors the whole proceeding. With the telephone, however, we can change all that. Just what can be done in this direction was indicated in New York the other day, under circumstances which deserve to be given with a little minuteness. The sheriff had received an attachment for $2,200 against George P. Altenburg, banker and broker, at Cincinnati, Ohio, in favor of Frank A. Rothier, and a deputy sheriff had levied upon money in the hands of Purnell, Hageman & Co., bankers. The attachment was obtained only by taking an affidavit of the plaintiff over the long distance telephone direct to Cincinnati. The suit was brought to recover money deposited by the plaintiff with the defendant, individually, to invest for him in Western Union and other shares. He alleged that Altenburg did not invest the money given him, and refused, when asked, to return it. As Rothier desired to attach property in New York City belonging to Altenburg, it was necessary for him to make an affidavit that the facts, as alleged, were true. His counsel, Horace E. Deming, was anxious to act upon the attachment at once, but was puzzled how to do so. when Joseph G. Dean, of counsel for the plaintiff, suggested that they should take his affidavit by telephone. This was agreed to, but another difficulty then arose. Neither of the lawyers here knew Rothier's voice, and were aware that without being able to prove that the plaintiff was the person making affidavit over the wire, the attachment could not be obtained. Mr. Dean knew a gentleman in Cincinnati named A. K. Stello. The latter was called to the telephone and requested to bring Rothier to the sender. Mr. Dean stated that he recognized Stello's voice, and next spoke to Rothier, whom Stello identified as Frank A. Rothier. This man proceeded to make the necessary affidavit, but when it was concluded, another puzzle confronted Mr. Dean. It was how to have the affidavit signed and sworn to before a New York notary public. Mr. Dean administered the oath usual in such cases to Rothier, and then affixed his name to the affidavit, stating it was sworn before him. Stello made an affidavit swearing to Rothier's identity, and Mr. Dean made a third affidavit setting out all the facts as to the proceeding. Upon this testimony the attachment on which the levy was made was granted. If this splendid illustration of the way in which the law's delays can be abbreviated and circumvented, by the telephone, does not have some effect, we shall be greatly in error and sadly disappointed.

MAXIM'S NEW INCANDESCENT LAMP.

A CABLE dispatch to the New York "Journal" last week announced that Mr. H. S. Maxim had invented "the finest, cheapest and strongest electric light ever made, with nearly three times the candle-power of the ordinary incandescent light." We are also informed that it lasts more than twice as long as, and requires less than half the energy of, the present type of incandescent lamp. We will not go into the details of the economy of the lamp as given in the dispatch, as they are somewhat mixed, and we would not care to hold Mr. Maxim responsible for the vagaries of the newspaper correspondent. But what is most important is the fact that the new Maxim lamp is said to have a mineral filament. Although the name of the mineral is not given, it is safe to infer that the substance is derived from some of the rare earths containing zirconium, caesium and their related elements. Lamps of this type have been made in the past, but have not come into general use for various reasons, principal among which is their high cost. We are informed that Mr. Maxim's new mineral filament costs 1 cent. While this figure is relatively considerably higher than the cost of a carbon filament, it would by no means be prohibitory, if the new lamp answered other practical requirements of efficiency and life. As to the former point, we believe that tests have shown decided economy, but we know of no authentic life tests on this type of lamp. The carbon filament has held its own remarkably well during the ceaseless struggles for a better filament, but that is no reason why one should give up hope of ever beating it. The Welsbach mantle, a mineral filament, as it were, has certainly given gas a decided impetus, and there is no reason why electrical engineers should not call the rare earths to their aid to put the electric incandescent lamp still further above competition. Mr. Maxim's lamp will bear watching. At least, there is nothing chimerical about it.

GOVERNMENT TELEGRAPHS AND OTHER THINGS.

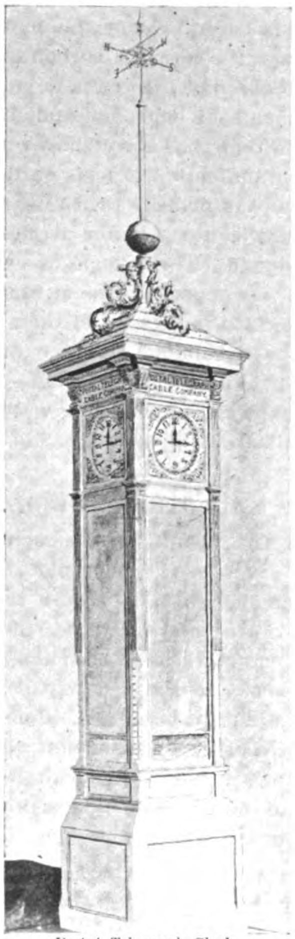
JUST at a time when the New Orleans "Times-Democrat" is extolling the beauties of government telegraphs, the operators in England are "kicking like steers" because they are dissatisfied with the state of things; and in France there is a scandal because the government wires have been tapped to sell news for the London "Times" to Paris newspapers. These unhappy coincidences should not be permitted. Consul Monaghan, at Chemnitz, Germany, has sent to the State Department a report which, speaking of the government railroads, says: "No other branch of public property pays so surely and well. . . . Their quasi-public character has helped the people to understand that they should be controlled at least, if not owned, by the State." At this very juncture appears a letter in the "Evening Post," which, in speaking of unfavorable conditions in Germany, says that among the causes responsible for the unsound condition of agriculture in the eastern half of Germany "the unreasonably high freight rates charged by the railroads, owned by the State, mind you, are among the most important. These freight rates are so high that they double, treble and even quadruple the original prices." The letter goes on to explain why this country is thus able to flood Germany with apples, and why the inland Germans get so little sea fish and shell fish, even when the salt water is only fifty miles away. Mr. Monaghan had better study his theme deeper or come home.

PRICES GOING UP.

SO many articles of everyday use are now advancing in price, it is only reasonable to expect that electrical materials and apparatus will soon fall in line. Some of the quotations on electrical goods, such as wire, dynamos, motors, are little short of absurd, and, as we said the other day, there must be a change. The competition that has existed for some time past in the endeavor to find some lower depth yet for prices, has now got to cease very soon. It may be questioned whether so large an amount of material, for example, has ever been sold on so minute a margin of profit, as has been seen in the case of electrical wire during the last two years. Nobody has benefited in the slightest degree, not even the purchasers, and they should be among the first to enjoy good results from a return to the normal conditions of cost and profit.

TELEPHONY AND TELEGRAPHY

THE POSTAL TELEGRAPH CLOCK.



Postal Telegraph Clock.

A VERY ingenious and useful innovation in the direction of furnishing the public with the correct time, free of cost, has been made by the U. S. Time and Weather Service Co. of this city. The idea involved in the plan is to set up in different and prominent places in each city a number of tall, handsome clocks, which shall give exact United States time, and which drop a ball at high noon. This scheme has been successfully worked out in connection with the Postal Telegraph Cable Company, over whose wires the time service is sent and whose name is placed conspicuously on each clock. A large number of these clocks have already been set up in the West, the number in use by January will be between 100 and 200, and the Postal Building in Broadway is to have one placed before it immediately. Mr. F. E. Sutton, the secretary and treasurer of the Time Company, tells us that the service is proving very popular, and that "Postal time" is already a standard, well known phrase in many a Western city.

We illustrate the clock herewith. It stands about 18 feet high, all told, and the gilt ball, 10 inches in diameter, under the weather vane is dropped three feet at noon exactly each day by the usual method of time signaling. Over the clock dials is the name of the Postal Company. Under the clocks are large panels, about 18 inches by 63, which are filled up with local and special advertising. Beneath these are smaller panels which give each morning the latest United States weather reports, two or three hours before they appear in the afternoon papers. At the corners of the stand on the street side are a thermometer and a barometer. The clock stands are made of cast iron, bolted securely to the sidewalk paving, and are handsomely painted white and gold, or sage green, etc., as may be desired. Ordinarily the streets on which the clocks are placed are well enough lit to enable the time to be read easily without extra light, but arrangements have also been made, when necessary, to illuminate by electricity the clock faces and also the advertising panels. So pleasing is the general effect of these clocks, they have already been ordered to be placed in front of several city halls. The United States Time Company has organized three or four sub companies to take care of the business in different sections of the country.

THE BEAUTIES OF GOVERNMENT TELEGRAPHY.

Even if the reports from densely populated European countries like England and Germany should prove as favorable as 'could be desired, they would afford little argument for the establishment of a Government telegraph system in this country under vastly different conditions. But apart from the enormous burden of such an attachment to the Government machine, there are other considerations which might well give pause to the most enthusiastic advocate of Paternalism. Take one example of the practical operation of the system: Fourth of July last fell on Sunday, as is the case frequently in a series of years. In some places the postoffices were closed, in observance of the holiday, on Saturday, July 3, and in others on Monday, July 5. As a consequence, there was a serious interruption of mail communication for three days of the week. But, fortunately, the private telegraph offices were open on all three days, and thus afforded much relief to business in the postal blockade.

Let the Government seize the monopoly of the telegraph, and the telegraph offices, like the postoffices, would be closed on every holiday. It need not be urged that the Government telegraph monopoly and the private telegraph companies cannot exist, here or in any country, side by side. In lowering the rate for telegrams (which appears to be the great desideratum with the champions of this scheme of Paternalism) the Government would make up the deficit out of the Federal Treasury, as is the case with the enormous and constantly growing postoffice deficit. But the private telegraph companies, having no such resource, must depend upon their earnings; and in competition with the Government machine they would soon be driven to the wall. The establishment of a Government monopoly would amount to the destruction of the capital invested by private telegraph companies. Whether a Government of equity can perform such an act toward its citizens is a question of public morality.

Under the Government postoffice system, which excites so much admiration on the part of the votaries of Paternalism, there is no responsibility for the loss of missives carried by mail. The kindly Paternal Government will register your letters, and if the money contents shall be rifled by one of its agents you may whistle for your loss. Express companies and all other common carriers guarantee the safe delivery of all articles entrusted to their care; Paternal Government alone is exempt from such obligation. Private telegraph companies are responsible for any loss or injury caused by the neglect of their agents in transmitting dispatches; under the Government telegraph monopoly the responsibility would cease. It may be said that the Government could make provision for making good all losses caused by its telegraph agents, but sad experience has taught the difference between the settlement of a claim for damages against a private company and the fate of a claim against the Government.—Philadelphia Record.

LITERATURE

L'ECLAIRAGE A L'ACETYLENE.—(Lighting by Acetylene.) By G. Pellissier. Geo. Carre & C. Naud, Paris, 1897. 238 pp. 5½ x 8½ in. 102 illustrations. Felixble cover. Price, $1.50.

The author has sought to present as favorable an exposé as possible, of the actual state of the acetylene industry, devoting particular attention on the points of general interest, such as the possible dangers, the conditions to be fulfilled in the rational preparation and utilization of acetylene, etc. The subject is introduced by a brief description of the various electric furnaces which have been proposed and constructed for the production of calcium carbide, from which acetylene is produced. The preparation of acetylene for its commercial utilization occupies several chapters, containing descriptions of a variety of generators, some of which are of considerable ingenuity. The part devoted to the dangers of acetylene will make interesting reading to the advocates of electric lighting. We also notice a description of various types of acetylene burners. M. Pellissier has a very happy style of expression, and the book is interesting as well as instructive.

VORLESUNGEN UBER DIE ELECTRO-MAGNETISCHE THEORIE DES LICHTES. (Lectures on the Electro-Magnetic Theory of Light.) By H. von Helmholtz. Edited by Arthur Koenig and Carl Runge. Leipzig, 1897. Leopold Voss. 370 pp., 6½ x 10 in. 54 illus. Paper. Price, $2.50.

The present volume of the lectures of the late H. von Helmholtz is the fifth of the series of his lectures on Theoretical Physics, and is published from the stenographic notes of Dr. Borchardt, taken in the winter semester of 1892-93, and in its greater part has been personally revised by the late Helmholtz. It gives the theory of light in its completed form, exemplified by formulas and equations, together with a historical review of the theory of emission and undulation.

MISCELLANEOUS

ON SOME NEW FORMS OF GAS BATTERIES AND A NEW CARBON CONSUMING BATTERY.[1]

BY WILLARD E. CASE.

IN 1839, Grove announced his discovery of the gas battery, considering it the most simple arrangement to produce electricity. He never considered it a practical way to generate electrical energy. Grove used platinum sponge or platinum black as the absorbent to facilitate the combination of the gases. The following experimental determinations by the author will show, as far as they extend, that platinum or its compounds are not necessary to produce the combination of the gases in the production of electrical energy, so doing away with one of the most expensive drawbacks to the gas battery. The experiments also prove that carbon is oxidized to CO_2 at normal temperature without the application of heat, with the production of electrical energy.

In these experiments, it will be noted that platinum is not essential to the reactions. Both electrodes in each case can be carbon tubes or plates. The physical condition of the carbon in its many forms plays a most important part.

The Chlorine-Carbon Cell.—A porous carbon-tube electrode, into which chlorine gas was passed, opposed to a carbon rod, which had been heated red hot, was placed in hydrochloric acid, of specific gravity 1.10. An e. m. f. of from 0.50 to 0.54 volt was obtained, depending on the condition of the carbons.

The carbon electrodes, after being heated, were again assembled and placed in distilled water. With no gas passing through, they gave an e, m. f. of 0. When the chlorine gas was passed into the carbon tube, at slightly above atmospheric pressure, the e. m. f. gradually increased to 0.44 volt at the end of twenty-six hours. On short circuit, 0.04 ampere was obtained, but it dropped rapidly to 0.02. The internal resistance was very high. The electrodes were taken out and the solution analyzed. It was found to contain hydrochloric acid and carbon dioxide. The same experiment was repeated in a dark case, to see if the action took place in the absence of light. The chlorine gas was made in the dark and passed through the electrode. The electromotive force gradually increased, as in the first case, showing that the action took place in the dark.

A carbon electrode, through which chlorine was passed, and a negative platinum electrode opposed to it, in dilute hydrochloric acid, gave 0.4 volt, but the electromotive force did not hold up through the voltmeter circuit. Both electrodes were covered with gas after short circuiting, and the e. m. f. dropped to 0.24 volt. On shaking, the voltage jumped to 0.4.

A negative carbon electrode was substituted for the negative platinum. It had been heated red hot and was very porous, the surface soft and rough. The e. m. f. reached 0.58 volt, and gave on short circuit 1.24 amperes, but dropped slowly to 0.3. The negative carbon electrode was oxidized.

A platinum electrode in a paper envelope, opposed to powdered carbon in the bottom of a glass jar in hydrochloric acid, chlorine being passed into the solution near the platinum. An e. m. f. of 0.60 volt, and on short circuit 0.9 ampere, were obtained. The current remained fairly steady. The surface of each electrode was about 45 square inches.

A cell made up as above, but with graphite instead of carbon, gave 0.54 volt, but dropped rapidly on short circuit, the graphite not oxidizing fast enough to give a steady current. A dense carbon rod opposed to powdered carbon gave 0.4 volt and on short circuit 0.2 ampere. The rod was encased in filter paper to protect it from floating particles of powdered carbon, and the chlorine passed into the solution near it.

Two small glass beakers connected by an inverted U-tube and containing hydrochloric acid, with a carbon rod in one and platinum plate in the other. When chlorine was passed into the vessel with the platinum, an e. m. f. of 0.48 volt was obtained. When chlorine was passed into the beaker containing the carbon rod, an e. m. f. of 0.14 was obtained, but it dropped almost immediately to zero. When chlorine was passed into both beakers, no e. m. f. was obtained.

The chemical reaction of the chlorine-carbon cell was as follows: $H_2O + Cl_2 = 2HCl + O$, the oxygen of the decomposed water attacking the carbon, and hydrochloric acid and carbon dioxide being formed.

[1]Read before the British Association, Toronto.

Carbon Monoxide-Chlorine Cell.—Cell made as follows: A glass tube, 2.25-inch bore and 6 inches long, corked at each end, with a porous tube, 1 inch outside diameter, passing through the glass tube and corks, and corked at each end, carbon rods and gas inlet and outlet tubes let into each chamber, which were filled with dry animal charcoal previously treated with hydrochloric acid. The porous tube was saturated with concentrated hydrochloric acid. Chlorine gas was passed through the outer tube. An e. m. f. of 0.18 volt was obtained. Then carbon monoxide gas was passed through the inner tube, and the voltage increased to 0.33 volt. A slight increase of the pressure of the gases increased the voltage. The glass tube became hot. This reaction would produce carbon oxychloride.

Marsh Gas-Chlorine Cell.—Two carbon tube electrodes, ¾ inches in diameter and 4 inches long, opposed to one another in a solution of hydrochloric acid, with chlorine passed into one and marsh gas into the other, gave an e. m. f. of between 0.6 and 0.7 volt, varying with the condition of the carbon. A current of 0.7 ampere was obtained on short circuit, but the cell rapidly polarized. Afterward, fresh carbon electrodes, with the gases passing through them, were placed in distilled water, and the e. m. f. gradually increased from zero to 0.14 in twelve hours. On testing the solution, hydrochloric acid and carbon dioxide were found to be present. The chemical reaction of this cell is as follows:

$$CH_4 + 4Cl_2 + 2H_2O = CO_2 + 8HCl.$$

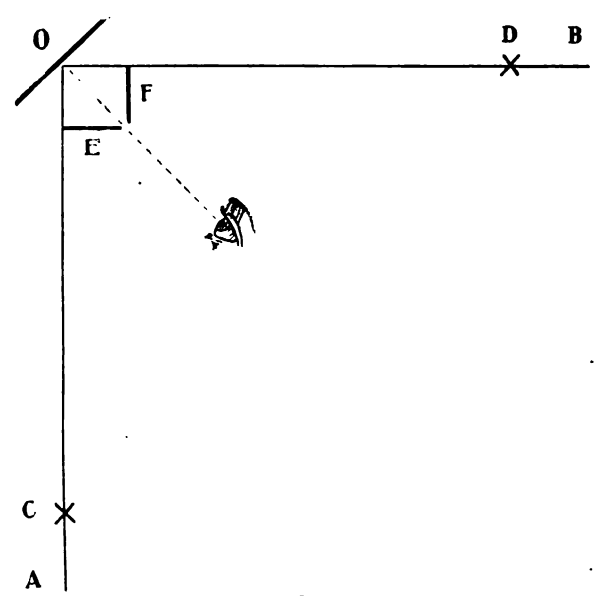
The calculated e. m. f. of this cell is 0.65 volt.

In making these determinations of electromotive force and current, a Weston direct reading voltmeter and mil-ammeter were used. Resistance of voltmeter, 352 ohms, reading from 0.01 to 3 volts. The ammeter read from 0.01 to 2.00 amperes. In all the experiments, the gases used were but slightly above atmospheric pressure. Owing to limited time, the author is not able to furnish further data. Experiments to determine the many interesting questions involved are being conducted.

Mr. C. E. Timmerman, of Cornell University, who has assisted me, has taken great care, with the limited time at our disposal, to verify these results.

PROF. S. P. THOMPSON'S NEW PHOTOMETER.

AT the Friday meeting of Section "A" of the British Ass'n, Prof. Silvanus P. Thompson described an ingenious and simple form of photometer, the main advantage of which is that it occupies less space than the usual forms in which the bench is quite straight. The new photometer bench consists of two parts, OA and OB, the joint O being conveniently placed in one corner of a small room, and the lights to be compared are placed at C and D. At O a flat disk or plate of white blotting paper is placed, screens at E and F serving to permit of one-half of the blotting paper being illuminated



THOMPSON PHOTOMETER.

by each source of light respectively. According to the well-known cosine law, if OD and OC are equal, and if the white screen be rotated until illuminated equally by the two sources of light on its two halves respectively, the intensities of the lights will be proportional to the tangent of the angle which

the blotting paper screen makes with one axis of the photometer bar. The material of the white screen must be destitute of specular reflection, and white blotting paper of not too smooth a surface has been found to be the most suitable.

ON THE FUEL SUPPLY AND AIR SUPPLY OF THE WORLD.[1]

BY LORD KELVIN.

LORD KELVIN commenced by sketching briefly the origin of fuel on the earth. He stated that the source of fuel is ancient vegetation, and classifies animal fuel also as vegetation, as all animals primarily feed on vegetable diet. He stated that probably no fuel existed on earth prior to the commencement of life on this planet, which he placed at less than 20,000,000 years ago. As a standard fuel he took one which required three times its weight of oxygen to consume it, and estimating the total amount of oxygen in the atmosphere he thus arrived at an estimate of the maximum possible amount of fuel in the planet. He neglected, however, the oxygen in the waters and solid matter of the earth. The total oxygen thus amounted to 1,020,000,000,000 tons, from which the weight of fuel was estimated to be not more than 340,000,000,000 tons.

After briefly sketching the process of solidification of the molten earth and the crystalization of primary rock, Lord Kelvin made some comments on the fuel supply of Great Britain, which he stated was greater than could possibly be burned by the total amount of oxygen in the air lying immediately over the British Islands. The effect of sunlight in storing energy and fuel was next reviewed, and the interesting statement made that two tons of vegetation per square meter per thousand years is about the average power of sunlight, whether in German forests or in English hay fields.

THE SPECIFIC HEAT OF SUPERHEATED STEAM.[1]

BY PROFS. EWING, F. R. S., AND STANLEY DUNKERLEY.

IN these researches the mean specific heat of superheated steam between the saturation temperature and a few degrees above saturation was measured by throttling dry saturated steam at a pressure above the atmosphere through a porous plug down to atmospheric pressure, and observing the differences of temperature and of pressure on the two sides of the plug. The plug consisted of rolled silk, and the steam passed through it at sufficiently slow rate to obviate any errors arising from the velocity of the steam. The extraordinary result was obtained that the specific heat of superheated steam is lower for temperatures near the temperature of saturation than for temperatures considerably above the saturation point, a result which appears at first sight to be contrary to the usual conception of the properties of steam just beyond the saturation point. These researches have not yet been completed and the value of the specific heat has not yet been absolutely determined. It is intended to pursue the investigation in regard to steam throttled down to pressures higher than that of the atmosphere.

THE ELECTRICAL DETERMINATION OF SPECIFIC HEAT.[1]

BY PROFS. H. L. CALLENDER, F. R. S., AND H. T. BARNES.

THE paper described a new method of determining the specific heat of a liquid in terms of the International Electrical Units. The researches were the outcome of the circular issued at the Liverpool meeting of the British Association last year, in which a method of evaluating the unit of heat was specified. The method adopted by the authors is an electrical one and consists in balancing the heat generated by a current against the heat carried away by a steady stream of liquid. The method has the advantage that all the conditions are steady. The electrical measurements were made with a Thomson-Varley slide box, and the temperature measurement by means of two platinum thermometers. In order to minimize the loss of heat by radiation a vacuum jacket surrounded the apparatus in which the heat was generated. The main object of the research was to find the variation of specific heat with temperature, but this part of the work has not yet been completed. The paper is accompanied by the following table:

Specific Heat of Mercury.

Rise of temperature = $d\theta$.	Liquid flow = Q.	$= 0.1600\,Q\,d\theta$.	Watts = EC.	Diff. = EC—$0.1400\,Qd\theta$
12°.301	4.594	7.912	8.488	0.576
11°.872	6.740	11.202	11.696	0.494
11°.764	8.753	14.418	14.862	0.444

The value of the sp. ht. of mercury at 28° C. was found to be 0.13905.

[1]Abstract of a paper read before Section "A" of the British Association at Toronto.

PROTECTION AGAINST LIGHTNING.

BY PHILIP ATKINSON.

THE dense ignorance, prejudice and misapprehension which prevails in regard to lightning rods, even among well informed electrical people, are responsible for most of the loss of life and damage to property caused by lightning. In nearly every electric storm, whether in the city or country, buildings are struck and often burned, and people hurt or killed. The cases of this kind reported in the daily papers show that, in the aggregate, this loss of life and property is enormous; and yet people, with ample and efficient means of protection at hand, submit to it, as something inevitable, the general impression prevailing that the lightning rod affords no protection, but is rather an additional source of danger.

An instance of this came under my observation recently. A friend consulted me in regard to the erection of a lightning rod on his house; and after giving him full and explicit instructions as to its construction, I sent him to a man whose specialty was wiring buildings, for information in regard to the nature of the copper which I recommended. This man, as I afterward learned, had certain antiquated notions in regard to lightning and lightning rods, and instead of giving the desired information, expatiated on the terrible risk and danger which would be incurred by erecting the rod, and so frightened my friend that he abandoned the project.

It is undoubtedly true that a badly constructed rod may be very dangerous, and worse than none; and that such rods are often erected by ignorant and unscrupulous men. But it is equally true that a good rod, properly erected, affords ample protection, and that such rods are exceedingly simple in construction, and can be obtained at very small cost.

Copper, in the form of ribbon, or tape, is the best and most convenient conductor for attachment to the house, as it lies close to the surface, fits snugly around cornices and other inequalities, does not mar architectural beauty by conspicuity, and is easily put up. But it must be soldered to an upright copper rod, extending 6 or 8 feet above the highest part of the roof, and terminating in one or more points; the lower end extending down to permanently moist earth, or a mass of iron.

If such ribbon is not easily obtained, the next best thing is copper rod, or wire, not less than No. 000 size, which can easily be had of sufficient length to extend from top to bottom without joints, which are always undesirable, and it can easily be bent into the proper shape to fit inequalities of surface.

The conductor, whether of ribbon or rod, should not be less in weight than six ounces to the foot, and should be attached to the building by straps of copper or galvanized iron, so as to be electrically connected with every part of it, especially with pipes, troughs and other metal parts, and not insulated from them, as is often erroneously done.

No better rule in regard to the height and number of the terminals projecting above the building, has been found than the old one, that the rod is supposed to protect a cone-shaped space whose base is twice the diameter of the height of the rod.

In these days when copper rod, or wire, of any size and of the best quality is cheap and abundant, there is no excuse for leaving a building exposed to lightning. Any one accustomed to wiring can easily construct and erect such a rod as here described at less than one-third the price usually asked by lightning rod peddlers for a rod which may be worse than worthless. The main terminal point can be made on the rod itself with a file, and a cluster of smaller points below it, by drilling two holes at right angles to each other, inserting cross-wires, which can then be soldered in place, turned up, and sharpened with the file.

With your house properly protected in this way, you and your family can go to sleep with a feeling of perfect security while the lightning flashes and the thunder crashes in close proximity above you.

On our modern high office buildings of steel and terra cotta it would doubtless be quite sufficient to extend copper termi-

nals from the top of the building and connect them with the mass of steel which forms the frame; as a charge of lightning, no matter how heavy, would distribute itself through this mass of steel, and pass off into the earth without damage, or any perceptible effect whatever; while, in the absence of such protection, it is liable to damage the non-conducting terra cotta and firebrick in which the steel is enclosed, or, perhaps, kill or maim the occupants. It is not long since one of the high office buildings in Chicago was struck by lightning and one of the ornamental turrets damaged.

RELATIVE ECONOMY OF WELSBACH LIGHTS.

BY G. I. K.

IN looking over The Electrical Engineer of June 23, 1897, I noticed an article on the subject of "Welsbach and Fuel Gas." As far as the fuel gas question was mentioned, I believe that the writer took the correct view, but as to the comparison between the Welsbachs and the incandescent electric lights, the statements in the above article are apt to be misleading.

I refer in particular to the report of G. W. Baird, U. S. N. It would appear from this report and comparison that this gentleman has not had any extended or practical experience with Welsbachs, as his deductions (as briefly summarized) in the matter are not substantiated by the experience of others, at least with the Improved Welsbach Light.

The basis of 3.2 watts per candle-power is seldom accomplished in actual practice, but assuming this as a comparative standard, we will look to the gas side of the question. 3,200 candle-power hours per thousand feet of gas means "sixteen candle" gas. This is not a fair rating, as the average candle-power of gas as now generally supplied is nearer 22 candle-power. This would make 4,400 candle-power hours per thousand feet, instead of 3,200.

Now take this thousand feet of gas and use a Welsbach light and the result is that we get fully sixty candles per burner (photometric test) and consuming not to exceed three feet per hour. This equals 20,000 candle-power hours per thousand feet, as against 11,200 candle-power hours of the electric incandescent, on the "dollar basis." In the matter of renewals, my own experience and what I have been able to learn from sources where the lights are used extensively, it has been found that the average of one mantle and chimney per 3,000 feet of gas consumed is practically correct. This is based upon their use for interior lighting, both commercial and residence. This makes the cost of renewals about one cent per 1,000 candle-power hours.

With the average life of the electric incandescent light, if the same is burned to its approximate candle-power, the cost of renewals (at 20 cents per 16 candle-power lamp) would be about one cent per 500 candle-power hours.

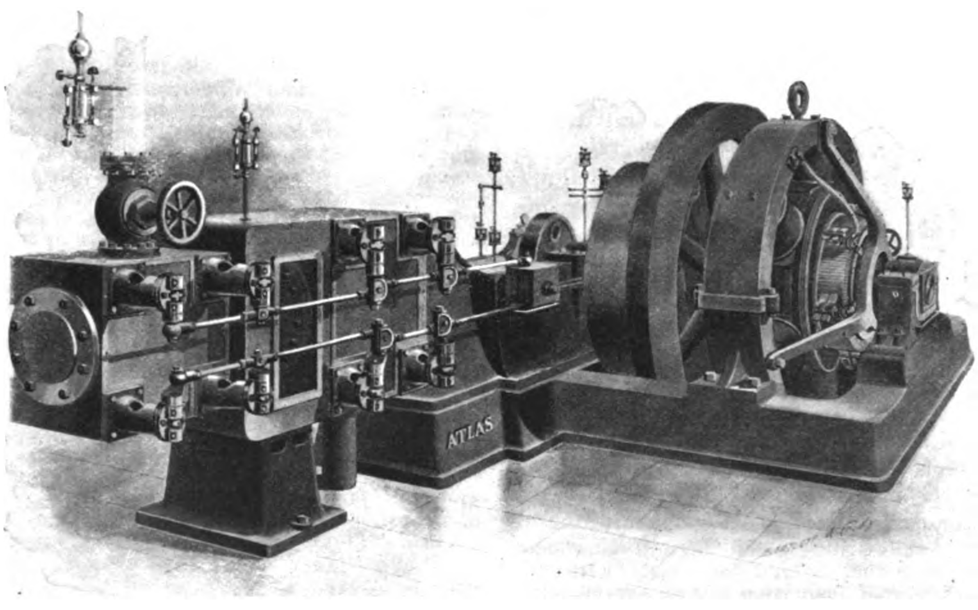
As to the gas companies looking upon Welsbachs with disfavor, it seems a short sighted policy, as anything that improves or cheapens a lighting service either in gas or electricity will ultimately result in a larger and better business for the manufacturer. Neither gas or electrical companies can afford to use or advocate obsolete apparatus or methods, and as the manufacture and distribution of "light, heat and power" in these two lines are becoming more closely allied, and the field of each more clearly defined, there is less ground for controversy, and the success and advancement of either branch will develop a greater field for both.

ATLAS CYCLOIDAL ENGINE IN ELECTRICAL WORK.

THE Cycloidal heavy duty engine, illustrated by half-tone cut on this page, was designed to meet the demand for a moderately high speed engine, which can be directly coupled to electric generators and operated with high steam economy. The showing which this engine has already made for itself is very satisfactory and has commanded the attention of steam and electrical engineers. Careful tests are said to have shown it to be more economical than the Corliss type of engine, and without having the restriction of comparatively slow speeds imperative with the familiar Corliss style of releasing valve gear.

The general appearance of a tandem-compound direct coupled unit is shown by the cut. The engine is designed for the heaviest kind of duty; the bed plate is very massive, and has removable, adjustable main bearings. All bearings, pins and wearing surfaces are very large and carefully finished; cylinders are steam-jacketed, and fitted with two admission and two exhaust valves, all of the multiported gridiron type, having flat wearing surfaces and removable seats. Admission and exhaust valves are separately operated, the admission valves being closed by direct steam pressure. Steam ports are very short and direct, and the steam clearance is reduced to a minimum. This valve gear is capable of very close adjustment, the valves are quick opening and closing, with very short travel, and give a long range cut-off. The engine is fitted with the latest improved oiling devices, and can be thoroughly lubricated while under continuous running at full speed. The governor is of the inertia type, is mounted on main shaft and gives extremely close regulation. The engine can be furnished either simple or compound, direct coupled to generator, or direct belted if desired.

The Atlas Engine Works, of Indianapolis, are the designers and builders of this engine. They have a special department with the best methods and appliances for the manufacture of high grade engines. This company has also recently brought out the Improved Atlas-Corliss engine, which we shall hope



THE ATLAS CYCLOIDAL ENGINE.

to have an opportunity to present to our readers with descriptive matter and cuts in a future issue. To Mr. A. M. Morse, manager Chicago office, 1108-9 Marquette Building, we are indebted for the above data, and may add that he will be glad to furnish further information to parties interested.

POWER FROM THE NIAGARA RIVER AT BUFFALO.

APPLICATION has been made to the War Department for permission to Sylvester N. Stewart, inventor, and J. C. Graves, trustee, to use the current of the Niagara River near the east shore and between a point opposite Fort Porter and a point 500 feet south of Ferry street, Buffalo, for the development of power where the same will not obstruct navigation, and this statement has been filed with the application:

"The city (Buffalo) has for a long time been desirous of utilizing the current of Niagara River for the generation of power for commercial purposes. At one time there was offered a reward of $100,000 for any apparatus that would accomplish the purpose. Mr. Sylvester N. Stewart has invented a horizontal shaft with paddles arranged in the form of a spiral, which by trial in the current has proven to be effective. This apparatus has been exhibited before committees of the Merchants' Exchange and Real Estate Exchange, who have given it their approval and commendation, asking the general, State and municipal governments to grant privileges that will permit of its use in the Niagara River. Application has been made to the State board having in charge the breakwater pier running between the river and Black Rock harbor for permission to take the apparatus on such pier, and if such application is granted and the use of the current permitted where navigation will not be obstructed, it is expected that power will be generated for public use at very low cost. If such permissions are obtained it will be agreed that power shall be furnished at $20 per horse-power per year for 24 hours' use each day."

The application and papers have been referred to Major Symons, United States engineer, for his opinion and report. A very significant statement is that made by General Graves, when interviewed relative to the above petition. He said: "The fact is, that Buffalo, for all the newspaper talk, can count but little on securing any large amount of electric power from the Falls for some time to come, and, perhaps, never. Buffalo will only get from Niagara Falls the amount of power which the company cannot sell down there."

DANGER IN ELECTRIC MINING WORK.

In the "Mining and Engineering Journal," "S. T. J.," of Florence, Colo., writes as follows: I read with interest the article in the "Engineering and Mining Journal" of July 17, on "Precautions Against Fire in Metallurgical Works," and wish to call the attention of parties interested to the risks of fire in many of the mills and reduction works throughout the West, arising from the manner of installing their electric plants. It is no uncommon thing to see wires conducting direct current 120 to 500 volts strung about the mill on wooden cleats, and drawn through timbers and floor joists, with only a low grade of weather-proof insulation to protect the wires and prevent leaks and short circuits. Another practice that ought to be prohibited—and soon would be if the insurance companies would refuse to take risks on buildings where it is done—is running circuits with wire as small as No. 16 B. & S. guage. This is sometimes done simply to make a cheap job, though if there is any class of work that pays to have well done, it is electric work. Another error is in wiring small isolated plants with so heavy a loss in the conductors. While this class of work is somewhat cheaper in the beginning, it is extremely expensive in the long run, both as regards fuel and lamp renewals.

ELECTRIC POWER IN A SCRANTON COAL MINE.

An electric locomotive in a Scranton coal mine shows a saving over mules of $2,528 in 200 days. The electric pump in the mine showed a saving over steam pumps of $1,513 in 970 days.

CARD SPECIAL FACTORY MOTORS.

TO meet the demand for special motors, to drive tools, etc., and occupying little space, the Card Electric Motor Company, of Mansfield, Ohio, have brought out the motor shown in the accompanying cuts (known as their S type), which can be

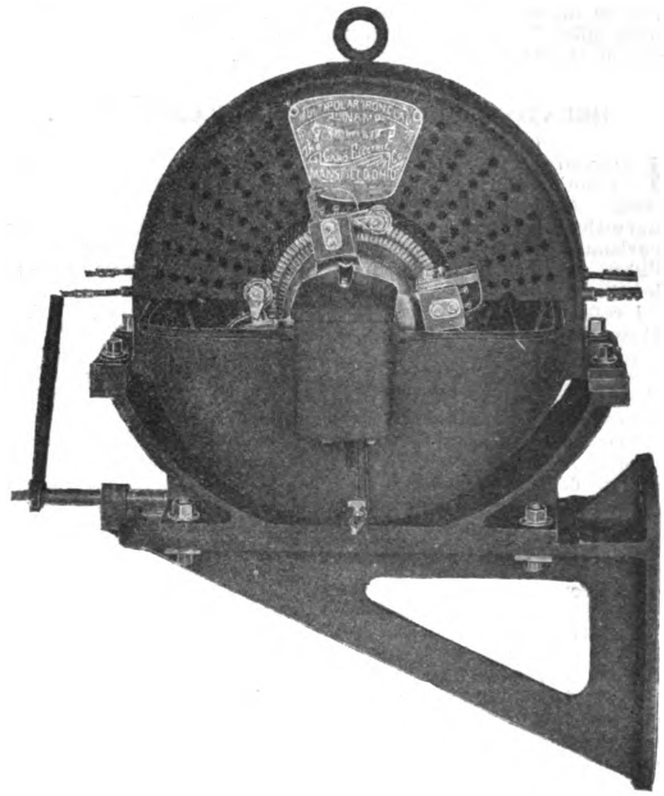


Fig. 1.—Card Special Factory Motor.

set on the floor, or supported from a post or wall, or suspended from the ceiling. Fig. 1 shows the motor with a bracket support for fastening to a post or wall. By changing the position of the armature bearings, i. e., turning them one-

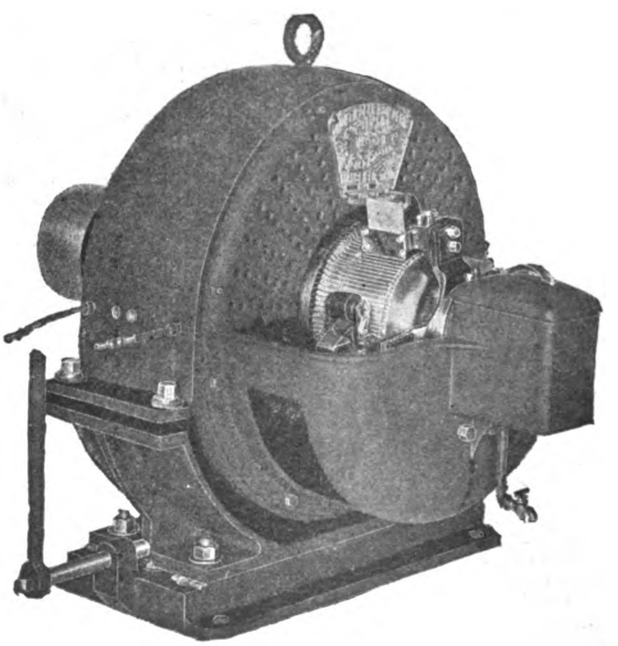

Fig. 2.—Card Special Factory Motor.

half round on the pole frame, the bracket will be brought above the motor which will then hang down. When the driving belt is to run horizontally from the motor or nearly so, this style of support is desirable, since the belt tightening screw is in the best position for quick adjustment.

The style of base shown in Fig. 2 is adapted to support the motor on the floor as shown in the cut, or by changing the position of the armature bearings, in order to keep the oil boxes right side up, from the wall or ceiling; and when the belt is to run nearly vertical this style of base is better than the bracket for wall support, because of the better position of the belt tightening screw. It is obvious that these motors can be used to drive shafting by gears as well as by belts when it is desirable to do so. As motors of this kind are frequently fastened to iron girders or posts in buildings, and therefore grounded, protection to the armature and field coils is provided for in the construction, by heavy insulation between the pole frame and base. In all other ways care has been taken to insure rigidity and lasting qualities. These motors are made in sizes up to 15 h. p.

ELECTRIC LIGHTING

THE EVOLUTION OF ELECTRIC LIGHTING FIXTURES.[1]

BY RICHARD N. DYER.

TO a manufacturer or dealer who entered the business after the present constructions had become standard, and without knowledge of the travail which preceded that result, electric and combination pendants appear to be only the ordinary gas fixtures with the wires and insulating joints added, and with such simple changes in construction as are required to accommodate those conditions. Back of this, however, there is a history which has never been and probably never will be fully written, and which is known only in part to those few manufacturers and dealers who participated in the early introduction of the incandescent electric lamp.

That lamp was invented by Mr. Edison in the summer and fall of 1879, and was publicly exhibited in operation on a considerable scale at Menlo Park, N. J., during the Christmas holidays of that year. The exploitation of this lamp as a substitute for gas for interior illumination was undertaken by The Edison Electric Light Company. During the year 1880, the only plant worth noting was that on the steamboat "Columbia," of the Oregon Navigation Company, plying between Portland, Oregon, and San Francisco, Cal. This boat had oil fixtures to which were added crude attachments for supporting incandescent lamps. The fixtures were made by Williams, Page & Company, of Boston, Mass. They were special constructions, which have never been repeated, and which furnish no indication of how to build pendants suitable for general use for the lighting of houses.

In February, 1881, The Edison Electric Light Company rented the dwelling house 65 Fifth avenue, located on the east side of Fifth avenue just south of Fourteenth street. It undertook to equip this building with a complete electric lighting plant which would show the possibilities of the incandescent lamp for interior lighting, both for offices and household uses. The rooms were to be provided with pendants corresponding in number and location to those which had been used in the house for gas, with a newel post standard, with a slide fixture, and with brackets. All these fixtures were for electric light only, no combination arrangements being included. The slide fixture and the brackets were special constructions, and are not interesting for the purposes of this paper. The contract for these fixtures was given to Mitchell, Vance & Company on specifications furnished by The Edison Electric Light Company. Mitchell, Vance & Company did the metal work, and called in Mr. Charles R. Hinds, a gas-lighting electrician of reputation, to furnish the electrical devices in accordance with the specifications. The fixtures were built on a patented idea of Mr. Edison's involving the "knock-down" principle. They were brass-finished fixtures, of a selected design for gas work, and were provided with large bodies open at the bottom, and in these open bodies were located large circular blocks of vulcanized fibre, upon which the electrical connections were made. Each arm of the fixture was wired complete, and the wires terminated at the inner end of the arm in two insulated contacts corresponding in principle to the contacts on the base of an incandescent lamp. The block of vulcanized fibre secured in the body of the fixture was provided for each arm with a set of insulated contacts corresponding in principle with the contacts in a lamp socket. The object was to enable the connections between the arm wires and the main or stem wires to be made by simply screwing the arm in place, and thus the fixture arms could be wired complete and the fixture taken apart or "knocked down" for shipment without disturbance of the wiring. The fixtures were not provided with any main stem wires by the manufacturers. These were to be provided by leaving the wires projecting from the outlet of sufficient length to enable them to be drawn through the pendant to its lower end and there secured by screws to the proper contact plates on the blocks of vulcanized fibre in the bodies of the fixtures.

The arrangements just described were actually carried out, the main wires being passed through the outlets by putting in T connections with the horizontal pipes in the ceiling, which T connections had openings at the center of the T for permitting the main wires to be run directly down through the outlet. The fixtures were delivered on March 15, 1881, and Mr. Luther Stieringer, at that time employed by Mitchell, Vance & Company, was given the work of erecting the fixtures. Stieringer was to have nothing to do with the electric work; that was in charge of an electrician for The Edison Electric Light Company. Difficulties arising from bad contacts, ground connections, etc., were soon developed; and after considerable tinkering to overcome these difficulties, Stieringer, with the consent of the Edison Company, took out the electrical contrivances in the fixtures and rewired them on the simple plan, at present employed, of soldering and tapping the joints between the stem and arm wires, and to avoid still other difficulties he opened the line of piping back of each fixture, leaving an air gap which cut off the fixture from the ground formed by the house piping. The result was satisfactory, and the electrical difficulties disappeared.

From this work Stieringer was brought to an appreciation of the fact that if internally wired fixtures of the general design of gas fixtures were to be made useful and were to be supported from the house piping, as he believed they should be in the case of simple electric fixtures and knew they would have to be in the case of combination arrangements, it would be necessary to provide a device which should form an effective mechanical connection between the fixture and the outlet, and an effective electrical separation or insulation between those parts. This resulted in the production of the insulating joint, two forms of which (one adapted for electroliers and the other for combination fixtures) Stieringer made about this time, the work being done at night at his house. It was some time later, however, before he had an opportunity to put his ideas to the test of practice, but these insulating joints he carried around in his pocket and showed to various people in explaining his notions relating to fixture work.

During the year 1881, several manufacturing establishments were organized for making the various kinds of apparatus required for incandescent lighting by the Edison Company, and an effort was made to get one or more of the gas fixture houses to undertake the manufacture of electric fixtures. None of these houses was found willing to go to the expense of developing the new forms and devices which would be presumably required, while they were quite willing to do work at the risk of the purchaser in accordance with specifications which might be submitted to them. Their position was thought by the electric light men to be antagonistic to the new industry, and perhaps it was, in the sense that there was no certainty that the new illuminant would furnish them with the same business opportunities as did the gas which it would replace; and, naturally enough, gas fixture manufacturers with an established line looked upon the new industry as involving experimental expense without an assured outcome.

In this situation the firm of Bergmann & Company was organized and a small shop established for the manufacture not only of fixtures but of miscellaneous small devices, such as sockets, safety catches and switches, which were not within the scope of the other Edison factories. That firm undertook the electric fixture business on lines quite independent of the gas fixture art. Their first pendants consisted of a simple iron pipe for the stem and a large cast iron body open at the bottom, in which the arms were screwed. The iron was given a bronze finish, and the bottom of the body was covered with a hard rubber cap, which, being black in color and presenting a different appearance from the finish of the fixture, was painfully conspicuous. A large block of wood was set in the body, and on this block were mounted plates to which the arm and stem wires were screwed. Circuit controllers having stems projecting through the hard rubber cap were also mounted on this block, as well as safety catches. These fixtures were provided with a crowfoot or with an equivalent device in the form of a closed cast-iron canopy with a flange for fastening screws; and whether provided with the crowfoot or the flanged canopy, the fixture was designed to be secured to a large base of wood, which, in turn, was attached to the

[1] A paper read before the National Association of Gas and Electric Fixture Dealers, Niagara Falls, August, 1897.

ceiling. The fixture as manufactured was wired complete in the arms, but the stem wires were omitted and were designed to be provided by wires extending from the ceiling which were to be drawn through the stem of the fixture and secured at their ends to plates on the wooden block in the body.

An improvement upon this construction introduced by Bergmann & Company was a similar fixture provided with stem wires which ended in a large plug attached to the top of the stem, this plug being similar to the base of the lamp, or to an attachment plug such as now employed, but made of wood and several times larger. To the ceiling was attached a large circular block of wood having a socket corresponding to the lamp socket, in which the ceiling wires terminated. By this plan a building could be wired complete, the wires terminating in the sockets in the ceiling blocks, and the fixtures could also be wired complete and could be attached in place by simply screwing the plug on the end of the fixture to the socket in the ceiling block, making at the same time a mechanical and an electrical connection.

A number of fixtures of the two kinds described were manufactured and shipped to the Paris Exposition in 1881, and a few, particularly of the kind supported by the crowfoot or flanged canopy, were put into use in this country. During this time electricians who did not care to use the Bergmann fixtures supported their lamps by means of such expedients as came to hand. Some gas fixtures were used with wires wrapped around the outside or carried to the lamps aërially, and in some instances a partial concealment of the wires was effected; but nothing in the way of a standard of construction was adopted except in the case of those fixtures manufactured by Bergmann & Company.

In the fall of the year 1881, Stieringer wired and hung, in accordance with his own ideas, electric light fixtures in the house of Mr. J. Hood Wright, in New York City, and in the spring of 1882 did similar work in the house of Mr. J. W. Doane, of Chicago. Both Mr. Wright and Mr. Doane were interested in the Edison business. Having thus demonstrated to his own satisfaction the success of his plan of using internally wired gas fixtures supported by insulating joints, Stieringer applied for his patents covering the use of the insulating joint in connection with electric and combination fixtures of this character. His work, however, had not so strongly impressed the electric light people as to effect a change in the character of the fixtures manufactured by Bergmann & Company.

The recognition of the merit of gas fixture designs for electric fixtures, and of Stieringer's method of using them, was of slow growth, and only came about by the gradual introduction of the incandescent lamp for interior illumination in locations where the users would not consent to the lack of ornamentation and artistic effect which had become a standard in connection with gas lighting. As the business grew, the frequency with which fixtures of this class were required, and the dangers from fire which their use involved, brought the subject to the attention of the fire insurance interests, who formulated rigid rules as to the separation of wires carrying the electric lighting current from each other and from other conducting bodies which, if enforced, would have prohibited the use of internally wired metallic fixtures. Indeed, the insulated wire at that time on the market was quite unsuited to the work, and it is questionable whether the fire insurance underwriters would ever have permitted the internal wiring of metal fixtures as a regular practice if improved forms of insulation had not been developed.

Stieringer's plan of introducing an insulating joint between the fixture and the outlet reduced the danger considerably, and in 1884 the New England Insurance Exchange adopted a rule requiring the employment of insulating joints when fixtures were hung from grounded supports. This requirement, which was adopted later by fire insurance underwriters throughout the country, together with the improved forms of insulated wire which were developed, resulted in the general adoption of the present standards of construction in the electric fixture business, and the gas fixture manufacturers, commencing first with the larger houses, and extending subsequently throughout the trade, took up the manufacture of electric and combination fixtures as a part of their regular business.

A review of the entire situation shows that it was the insulating joint and the ideas involved in its use which led to the present universal employment of gas fixture designs for electric and combination fixtures. Without the insulating joint, a form of insulated wire having a high insulation protected mechanically by some armor which would prevent abrasion might have been finally developed and would have enabled the safe internal wiring of metal fixtures without the use of the insulating joint. Such an improved insulated wire might have been produced as the result of the pressing demand for it in the absence of the insulating joint; but it is apparent that with the imperfect insulations which existed in the early days of the electric lighting art, and which still exist, the insulating joint is the foundation upon which the present electric fixture art rests. That joint and its use in this connection were invented by Stieringer and are covered by his patents, to which, in view of the meritorious results accomplished, full credit should be given.

To this very complete statement by Mr. Dyer may be added the fact that Mr. Maitland bought into the Stieringer patents in 1888. It is expected to have the suit against the Goetz Company argued at final hearing in the Circuit Court in New York early in the fall. Whichever way the case is decided, it will undoubtedly be appealed in the Circuit Court of Appeals for that circuit. When that court will decide the case cannot now be determined. The earliest possible date is about the end of the present year. When that decision is given, it will be the "ultimate" decision for that circuit, and probably for other circuits.

LETTERS TO THE EDITOR

MUNICIPAL PLANTS.—MR. A. E. WINCHESTER'S COMPLIMENTS TO MR. M. J. FRANCISCO.

SOME time ago my attention was drawn to an interesting article on "Municipal Ownership," from the facile pen of our oily-minded friend, Mr. M. J. Francisco, in the "Electrical World" of June 5. Now the writings of this learned gentleman, who has striven so unceasingly to fan the sickly flame of his little star of doubtful magnitude into sufficient brilliancy to be noticed among those which shine with the lustre of honest fame, are always interesting and instructive to me; interesting because of the deep and unselfish solicitude exhibited by him at every opportunity in behalf of unwary municipalities which have been so audacious as to assume that they had rights equal to those of private corporations to own and operate electrical plants. Instructive, because of his exhaustless fund of truly original statistics—undoubtedly gleaned only from his productive brain—which he generously ventilates before the public as facts, even ready to create opportunities where they are lacking in his anxiety for the public's good to sound his warning against the terrible consequences which, according to his views, are the inevitable results of "municipal ownership." He reminds one somehow of the oldtime, so-called temperance lecturer with his educated stock of horrible examples of the lowest extremes, which he endeavors to impress upon his hearers as pictures of what they are bound to come to unless they repent and follow his advice.

This particular article of friend Francisco's, however, was of unusual interest to me, for the reason that he devoted considerable of its length to an unwarranted attack upon the South Norwalk, Conn., municipal plant, the gratifying results of which seem to have caused him some anxiety, possibly because they have given practical proof to the contrary of his pet theories, and in order to maintain them and, being unable to call upon honest truths, to help him, he resorts, as a forlorn hope, to distortion and misrepresentation, a means of argument that no man possessed of a high standard of character would stoop to. Nor would any but a man of his methods unhesitatingly cast suspicion upon the honesty of those who are responsible for the management of that or any other plant who were utterly unknown to him. Right here it may be proper for me to explain that my interest in the South Norwalk plant is largely due to the fact that it was constructed some five years ago, under my supervision, since which time I have had the honor of being one of the board of three commissioners elected by our citizens to assume the responsibilities of its management.

Mr. Francisco's criticisms no doubt were sincere, according to his standard of measure, which seems to look only on one side, and probably his easy manner of jumping at conclusions when the facts were not to his liking, gave more or less color to his argument as it may have appealed to the uninitiated, but to one acquainted with the real facts it was perfectly clear that he had made extravagant use of assumptions that could emanate only from the combination of a pen and an unscrupulous writer.

Realizing the greatness of this man as one gifted with such long-distance penetration as to enable him to describe what he has never seen, and whose knowledge of central station

matters and municipal plants in particular is so voluminous, I felt too timid to attempt a reply to his article, and I trust he will pardon this effort, but in behalf of numerous friends from various sections of the country, not inclined to view things municipal in the same light as Mr. Francisco, who have been urging me to get up and say something, I at last in an unhappy moment consented, so the blame for my possible lack of discretion must rest upon them.

It would be becoming in me, I suppose, to proceed with fear and trembling and apologize for my extreme youth and the paltry dozen years of experience that it has been my good or ill fortune to have had in connection with central station work, but somehow as I have always been a direct current sort of a fellow rather than one of the high frequency order, it is difficult for me to produce much of a tremble. First, I would like to state that in so far as the South Norwalk plant is concerned, Mr. Francisco knows nothing of his subject, never having honored it with a visit, as is evidenced by what he has said concerning it, although he is most cordially invited to call at any time with full liberty to examine with microscopic nicety into every detail from the coal pile to the lamp trimmers' record. It would not take long as the plant is small, plain and simple; and it is managed on the same lines. Satisfaction and good results are all that we are after, and we get them. If he can discover anything contrary to what we publish in our annual reports or that will give the substance of truth to his allegations, he will have the distinction of being the first critic to succeed in such an attempt among the many experts who have visited the plant for the purpose of personal investigation. Some of them have even come armed with Mr. Francisco's funny little pamphlets, and nearly all have been biased against municipal plants in general. But they were honest enough without an exception to acknowledge that they found all as represented and extended compliments in place of criticisms.

The figures and quotations which Mr. Francisco alleges to have gathered from some of the annual reports of the South Norwalk plant indicate only a base attempt to distort facts, in the belief that no one would take the trouble to expose him. For instance, he asks if an armature was not burned out to account for an item which he knows was properly charged. But he would attempt to surround it with mystery so as to create a suspicion of irregularity which is groundless as the plant has never burned out an armature during the five years of its existence.

He further quibbles over the varying ratings of candle-power in the different reports, but fails to quote the careful explanation given. It is only necessary to state that the lamps used are of the Western Electric arc type, which adjust themselves to a varying range of amperes, and that the brilliancy is thereby increased or decreased as desired to suit requirements. An average nominal candle-power rating can only be obtained from the record of watts consumed. He tries to load an item for insurance upon the plant when it is fire-proof, and none is carried. Again, he adds 8 per cent. depreciation against the entire investment, when the real estate on which the plant stands has advanced in value and the 5 per cent. carried is ample. Then he speaks of a lawsuit for $20,000 against the plant. This is an absolute falsehood. In answer to his misleading statement concerning the tests of the plant made about a year ago, it is only necessary to quote the concluding remarks of the signed reports of the engineers who made them, which are as follows:

"The showing made by this test is very good considering the size of the plant and the conditions of load. The largest loss is in the boiler, where but 37 per cent. of the heat of coal is utilized. Good average practice for this type of boiler is from 60 to 65 per cent. The poor showing of this boiler is due to the fact that it is being worked at less than half its rated capacity. The performance of the engine was in conformance with good practice and would show up remarkably well if more heavily loaded. The performance of the station as a whole as regards coal consumption and cost of power compares more than favorably with stations having many times the output of this plant, and with a larger load the results would be highly gratifying to the designers and those in charge of the plant. (Signed) CHAS. E. BARRY."

Mr. Edgerton states in commenting upon the results of his report that "the above showing is considerably above the average of stations of equal or even greater output," and he highly commends the distribution of the lights on the streets as being "far more effective than 2,000 c. p. lamps at greater distances apart," and concludes by saying that results shown in the report are "due more to efficient management than to the excellence of the machinery."

(Signed) H. H. EDGERTON.

These were the exact and only data that Mr. Francisco had before him when he wrote, and I will add that they were made by two experts who visited the plant for personal investigation and were granted permission to make a complete test at their own expense, which they did with great care. It does not seem worth while to reply to any more of his assertions. Altogether too much space would be consumed by so doing, when the final result would only be to prove that he was wrong in every particular. To say that he has lied would be the plain English of it, and now it seems to me, in view of a charge so strongly put, that Mr. Francisco owes it to the position in which he has of his own free will placed himself, to prove his statements or admit the truth of the above; just how he can do either with grace is not plain, though his particular brand of resources will probably present a means satisfactory to himself, at least. If all of his statements concerning other municipal plants are as false as those in regard to the South Norwalk plant, which, I am quite inclined to believe is so from such information as has come to my notice, then his whole article must be substantiated with something more reliable than his mere assertions or pass as a mass of fabrication that will injure rather than benefit the cause he assumes to defend.

I do not consider myself qualified to advance extreme ideas for or against municipal or private plants, as my interests are with both, so long as either are conducted as public satisfying institutions; as to financial results and management I believe the two systems stand about even and my sympathies are drawn to the municipal side of the question only for the reason that I detest the injustice which has been so freely resorted to by those interested in private plants, whose agents have too often, as this man Francisco has done, cast honor to the winds, not hesitating to call to their aid lies and slanderous assumptions in the place of facts, which they dared not use, greedily grasping at isolated instances of mismanagement of municipal plants, which they have magnified out of all proportions, forgetting that such instances occur with equal frequency in privately owned plants. Undoubtedly Mr. Francisco himself could tell us of such a plant not a thousand miles from Rutland, with which he is quite well acquainted as an influential officer—a plant which, if hearsay is to be believed, has never given any remarkable signs of prosperity, notwithstanding the fact that it is under the eye of one who has constituted himself a criterion upon central station management.

I think sufficient evidence has been given herein to show the methods he uses in an agonizing effort to disprove the statements of honorable men unknown to him, who have no other aim but to do their duty and by so doing have earned his animosity by furnishing the most convincing proof that it is just as possible for a municipality to operate an electric plant with profit as it is for a private corporation to do so.

Our reports and business methods are open to all, and I defy Mr. Francisco to quote in full the passages and figures from which he has drawn his assumptions, so that those who may have innocently swallowed his story can see the truth, when possibly that old familiar adage will occur to them that "figures won't lie, but liars will figure."

ALBERT E. WINCHESTER.
Elect. Lt. Commissioner.

South Norwalk, Conn., August 17, 1897.

THE INCONSISTENCIES OF INSURANCE RULES.

My attention was called in your last issue to some inconsistencies in the rules of the National Board of Underwriters in reference to interior conduit wiring. These inconsistencies as pointed out are only a few drops in the bucket compared with what has been, or possibly may be, as long as vacillating ignoramuses in electrical matters are allowed to remain at the head of important departments. The criticism of "Bald Eagle," in comparison with former evidences of incompetence, is scarcely worth noticing.

This whole department of fire insurance has been secretly ridiculed from its incipiency by the well posted, common-sense members of the electrical fraternity; and justly, for to such an extent have they been foolish and contradictory in their rules for wiring buildings, that, in the minds of many (including some of their own inspectors, better informed than themselves) it has often been a conundrum whether they have done themselves, or, more correctly speaking, the insurance interests, more good than harm. To speak right out in meeting, there are a few who claim that some of the members have bettered their financial condition, otherwise than from a salary. There are others who believe that money "placed where it would do the most good" attended with a little sophistry in the way of argument, has been responsible for some of the glaring defects and absurdities in their rules.

In writing about these unpleasant matters I use a nom de

plume for business reasons, and personal ones as well. Some of us have found out that at times there is a disagreeable discrimination when it comes to the application of these remarkable and wonderfully drafted rules—in fact, we very soon find new, and unseen as well as unexpected, evidences of subtlety in ways that are dark and peculiar; and, strange to say, we soon commence to see more wisdom displayed than formerly in these insurance absurdities.

What we learn from experience we do not readily forget; I am speaking from experience, and there is no doubt of the vividness of my impressions.

Then, again, there has been discrimination where the rules do not apply. The independent position of the board, from whose decisions there is no court of appeal, has placed manufacturers at their mercy, and they have in instances been merciless until the manufacturers have found that something, other than argument, or tests, and demonstrations of the merits of their articles, talked louder than words, and carried more weight with certain individuals. They would say, in effect: "Whatever this board passes will be accepted all through the country. This is worth much money to you, and we should be paid (individually) for the prestige we give you." . . . This is not blackmailing, neither is it soliciting bribes; of course, not, for an even exchange is not robbery.

The personnel of the present board is not made up of this class of people, the writer has been recalling reminiscences of the long ago, and in speaking of those times let me, in justice, add that the inspectors and lower officials in general, especially in cities outside of New York, considered the honor of their position, and the salary connected therewith their sole recompense, until their merits could be recognized by a well merited advance, through close attention to the interests of the insurance they were paid to protect. SORE HEAD.

New York City, Aug. 24, 1897.

OBITUARY

A. DE LA M. LOZIER.

It is with extreme regret that we record the death of Mr. Arthur De La M. Lozier, assistant manager of the Bullock Electric Company, of New York City, from typhoid fever, at the home of his sister, Mrs. S. H. Payne, on Staten Island. Mr. Lozier had not appeared to be dangerously ill, and his death came with a great shock. He was only twenty-three years of age, a young man of great promise and ability, as well as of strength of character and amiability. He was a son of Mrs. Jennie De La M. Lozier, M. D., dean of the New York Medical College and Hospital for Women, and of the late Dr. A. W. Lozier, Mr. R. T. Lozier, of the Bullock Company, being his step-brother. Funeral services were conducted at the Episcopal Church, New Brighton, S. I., on Sunday afternoon, and were largely attended by friends of the family. Mr. Lozier was an associate member of the American Institute of Electrical Engineers, and was a chief signalman on the non-commissioned staff of the First Naval Battalion of New York. He took a lively and active interest in public affairs and in professional matters, and bade fair to rise high, but for his sad and untimely death.

EDWARD L. FRENCH.

It is with sincere regret that we have to announce the death of Edward L. French, which occurred quite suddenly, on August 21, at St. Vincent's Hospital, Toledo, Ohio. Mr. French recently met with an accident while at Put-in-Bay, O., which caused an injury to his spine, and while in the hospital succumbed to an attack of paralysis. Mr. French has for some time past been one of the traveling representatives of the American Electric Telephone Company, of Chicago, and was greatly esteemed by his employés, as well as by all his business and personal friends. He was twenty-six years of age, and his numerous acquaintances will mourn his untimely decease.

MR. C. W. KORNER, or Laurel, Md., writes: "By reading The Electrical Engineer I am kept posted on up-to-date electrical engineering."

NEWS AND NOTES

DATA OF TROLLEY ROADS IN NEW JERSEY.

A supplemental report of the State Board of Assessors, giving advanced statistics regarding the electric and street railroads in New Jersey for the year 1896, shows the total receipts of all the street railroads in the State for the year to be $5,770,171, against $5,056,598 in 1895, an increase of $713,573. The expenditures were $3,546,168, against $3,431,931 in 1895, an increase of $144,236, and dividends paid $124,220, against $117,320 in 1895, an increase of $6,900. The number of miles of track in the State is 613; capital stock paid in, $38,235,150; funded debt, $36,420,493, and other debts, $4,279,396; total of capital and funded debt, $78,935,039. The total cost of the railroads, including the equipment and appurtenances, is put at $80,011,559, an average of $130,500 per mile of track. The total assessed valuation of all steam railroads in the State, including roadbed, equipment, depots and depot grounds, terminals, bridges, franchises and all other tangible and personal property, is less than $95,000 per mile.

WHY THE LIGHT FLICKERED.

The Stamford (N. Y.) Electric Light Company uses wood for fuel instead of coal. The other night the lights were unsteady, flickering, etc. The next morning, a guest of Churchill Hall asked Engineer Corbin the reason the lights flickered, and Corbin told him it was "caused from burning the darn crooked wood."—Mirror.

PRODUCING OZONE ELECTRICALLY.

In the "Journal of the Society of Chemical Industry," M. Andreoli remarks that, though theoretically one should be able to produce a kilo of ozone per electric horse-power, in practice only 10 or 12 grams are obtained. By improvements, however, in apparatus for the production of ozone, M. Andreoli is now able, he contends, to increase the amount to 30 and in some cases even fifty grams per horse-power, making the cost about 75 cents a kilo. This, if a practical thing applicable on a large scale, is important. Based on these results experiments are to be made by him in various directions, to ascertain the value of the process in commercial affairs, such as the purification of drinking water, the cleansing of beer casks, preparing wood for instruments and furniture, bleaching of starch and dextrin, oxidation of drying oils, purification of wine and brandy, etc.

LEGAL NOTES

DECISION ON SPIRAL COIL HEATERS.

Mr. F. W. Kelley, assistant treasurer of the Consolidated Car Heating Company, of Albany, N. Y., writes us as follows under date of August 28.

We would be glad to have you print the following relating to our recent favorable patent decision in the next issue of The Electrical Engineer:

On August 25, Judge Putnam, of the United States Circuit Court for the District of Massachusetts, rendered a decision in favor of the complainant, with an order for an injunction and accounting, in the suit of the Consolidated Car Heating Company, of Albany, N. Y., against the American Electric Heating Corporation and the West End Street Railway Company, of Boston, Mass. This is the suit for the infringement of the patent to James F. McElroy, covering the Consolidated Car Heating Company's spiral coil construction of electric heaters, which is now used in the majority of street cars operating electric heaters in this country. It is considered a most important victory.

HART & HEGEMAN CO. VS. ANCHOR ELECTRIC CO.—SNAP SWITCH LITIGATION.

On August 20, in the United States Circuit Court, at Boston, Mass., in the case of the Hart & Hegeman Manufacturing Company against the Anchor Electric Company, Judge Putnam ordered the respondents to file a draft decree dismissing the bill with costs. This action was for the infringement of a patent for snap switches. In his opinion, Judge Putnam says that the Anchor Electric Company's manufacture is a device clearly described and fully covered by a patent issued to Norman Marshall, vice-president of the Anchor Electric Company.

Judge Putnam further finds that the switches manufactured by the Anchor Electric Company in nowise infringe the Hart patent, and, in conclusion, says: "If the complainant has any remedy it is not in the courts, but in convincing the purchasing public that the device of the respondents is less simple, economical and compact than his own."

C. F. Mitchell, New York, for complainant; E. P. Payson, Boston, for defendant.

DAMAGES FOR JUMPING FROM TROLLEY CAR.

Henry Poulsen sought to recover damages from the Nassau Electric Railway Company, of Brooklyn, for the loss of the services of his infant child, and on the trial of his action it appeared that the child saw a blaze of fire coming from the box alongside the motorman and becoming frightened jumped from the car and was injured. The Second Appellate Division has reversed the judgment below, dismissing the complaint, holding that the railroad company was called upon to explain the cause of the fire. Proof upon its part that a fuse blew out was not sufficient to exempt the corporation from the implication of negligence, the blowing out of the fuse not being ordinarily attended by any other display than a flash of light.

SOCIETY & CLUB NOTES

N. Y. STREET RY. ASSO'N will meet at Niagara Falls, Sept. 14 and 15; headquarters, the International Hotel.

A NATIONAL CONVENTION of mayors and city councilmen is to be held at Columbus, Ohio, September 28, 29 and 30 and October 1, when a large number of subjects of public interest are proposed for discussion. Mayor Black, of Columbus, is chairman of the General Committee.

THE EDISON CONVENTION will be held at Niagara Falls on September 14, 15 and 16, and both President Insull and Secretary Barstow look forward to a very large attendance and to an unusually good meeting in the way of papers and discussions. Headquarters will be at the Cataract House.

THE TORONTO MEETING.—Our esteemed contemporary, the "Electrical Review," states that it was the only electrical journal represented at the Toronto B. A. meeting. The matter is not one of much account, but we may say for ourselves that The Engineer was ably and specially represented by Mr. E. Tremlett Carter.

PERSONAL

E. G. ACHESON, president of the Carborundum Company, of Niagara Falls, was held up and robbed on the night of Friday, August 27, within a few doors of his home in Buffalo. Mr. Acheson had left his house, No. 41 Fargo avenue, to go to the depot, intending to take a train for Pittsburg. It was 11 p. m., and Mr. Acheson's cry of "Murder" startled the neighborhood. He was picked up unconscious and carried to his home, where he revived and described how three young men had attacked him. Two severe scalp wounds told of their ugly work. Mr. Acheson was relieved of his gold watch, a memorandum book and some private papers, but the book and papers were dropped by the thieves. The police believe he was struck by brass knuckles. What money Mr. Acheson carried was in an inside pocket, and this the thieves did not get. While Mr. Acheson's injuries are severe, his full recovery is early expected.

MR. SETH C. ADAMS advises us that he has resigned his position as secretary and treasurer of the Bossert Electric Construction Company, of Utica, N. Y., taking effect this week. Mr. Adams has not yet made any definite plans for the future.

HOMEWARD BOUNDERS.—Among the recent arrivals from Europe of people well known in the electrical field are Messrs. C. O. Mailloux, R. W. Blackwell, H. F. Parshall, John McGhie, A. C. Shaw, E. J. Wessels and G. T. Montgomery.

MR. G. R. SCRUGHAM, of the Creaghead Engineering Company, Cincinnati, O., is a special committee of the street railway and electric supply men of Cincinnati to get the next meeting of the American Street Railway Association in that city. Why not?

MR. C. F. HUTCHINGS, who has been superintendent of the Wilmington, Del., City Railway Company for the past two years, has resigned. Mr. Preston Lea, the president of the company, becomes general manager, and Mr. H. B. Vandegrift assistant to the general manager.

MESSRS. CREHORE AND SQUIER have been making some successful demonstrations in England, between London and Birmingham, with their new system of high speed telegraphy.

PROF. W. S. FRANKLIN, of the Iowa State College, has succeeded Prof. H. W. Harding in the chair of the department of physics and electrical engineering, at Lehigh University. Prof. Harding had held the chair twenty-five years. The trustees in accepting his resignation have made him emeritus professor of physics.

THE STOCK MARKET

STEADY ADVANCES.

THE general gains in trade and finance reported last week still continue. Bank clearings and railroad earnings are all higher again, a great many staples have been firm in price or have advanced, and considering the season of the year the number of industrial plants set going again or becoming more active is remarkably large. There is every indication that the fall trade will be unusually good.

On the New York Stock Market last week 36,795 shares of Western Union were sold, rising from 92 up to 93⅛. Of General Electric, 11,445 shares were sold around 37½. American Bell Telephone on sales of one or two hundred shares reached 240.

COPPER is firm at 11¼ cents for Lake Superior ingot, and 11 cents for electrolytic.

REPORTS OF COMPANIES

THE PENNSYLVANIA-SIEMENS HALSKE COMBINATION.

Formal consolidation of the Siemens & Halske Electric Company, of Chicago, and the Pennsylvania Iron Works Company, of Philadelphia, has been effected. It was announced last week that all but about 300 hundred shares of the capital of the Siemens-Halske Corporation had been exchanged for stock of the Pennsylvania Company, so that the latter is now in the control of the Chicago Corporation. The offer of the Pennsylvania Company to take over the stock of the Chicago concern became operative June 17, and the shareholders of the Siemens-Halske Company were given sixty days, or until August 17, to accept the proposition. The option expired, consequently, with the result, it is said, that every shareholder in this country has made the exchange. Friends of those absent have assured the chairman of the committee having the matter in charge that their stock would in due course be also exchanged. The general manager of the Pennsylvania Company, B. W. Grist, is now in Chicago and is managing the Chicago works. The Pennsylvania Company's letter-heads announce that it is operating the Siemens-Halske electric works of Chicago. The capital of the consolidated concern would, it was announced a short time ago, be $5,000,000, and that it would be

listed on the leading stock exchanges of the country. The issued capital of the two corporations stands as follows:

	Penn. Co.	S. & H. Co.	Total.
Preferred	*$1,750,000	$700,000	$2,450,000
Common	1,500,000	1,275,000	2,775,000
Total	$3,250,000	$1,975,000	$5,225,000

*Six per cent. non-cumulative.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUGUST 17, 1897.

Alarms and Signals:—

ELECTRIC BURGLAR ALARM. C. Coleman, Chicago, Ill., 11,626. Reissued. Filed Nov. 10, 1896.
Employs a meter connected to the main circuit and adapted to complete the alarm circuit upon a variation in the current.

Batteries, Primary:—

APPLICATION OF SOLAR HEAT TO THERMO BATTERIES. H. C. Reagan, Jr., Philadelphia, Pa., 588,177. Filed May 15, 1896.
Employs mirrors to focus the sun's rays to one set of junctions and means for cooling the other set of junctions of the battery.

Batteries, Secondary:—

ACCUMULATOR BATTERY. J. V. & H. H. Sherrin, London, Eng., 588,189. Filed March 22, 1897.
Each element consists of a core of non-conducting material, a lead conductor strip wound helically around the core, and an outer non-conducting strip wound helically around the lead strip in the opposite direction.

Conductors, Conduits and Insulators:—

ELECTRICAL CONDUCTOR. J. D. Bishop, New York, 588,382. Filed May 6, 1897.
Composed of a plurality of wire ribbons wound side by side longitudinally of the conductor and having intervening air spaces.

Dynamos and Motors:—

COMBINATION VOLT GRADUATOR. W. J. Shields, New Wilmington, Pa., 588,246. Filed March 24, 1897.
Details of construction.

DIRECT CURRENT GENERATOR. B. G. Lamme, Pittsburg, Pa., 588,279. Filed May 8, 1896.
Details of construction.

BRUSH HOLDER SUPPORT FOR ELECTRIC GENERATORS AND MOTORS. S. H. Short, Cleveland, Ohio, 588,490. Filed Jan. 2, 1897.
Embodies an adjustable rocker mounted concentrically with the commutator and a plurality of radially adjustable brush-holder hangers.

MULTIPOLAR DYNAMO, MOTOR, OR ROTARY TRANSFORMER. S. H. Short, Cleveland, Ohio, 588,491. Filed March 12, 1897.
Method of winding to reduce reluctance.

Lamps and Appurtenances:—

CARBON HOLDER FOR ELECTRIC LIGHTS. O. S. Moss, Syracuse, N. Y., 588,233. Filed Nov. 2, 1896.
Comprises a base having a concavity in its lower face and provided with lateral ears and side pieces, having eyes in their upper ends adapted to grip the carbon.

HOLDER FOR INCANDESCENT LAMPS. C. H. Otis, Orange, Conn., 588,348. Filed March 10, 1897.
Details of construction.

Measurements:—

METHOD OF AND APPARATUS FOR MULTIPLE RATE METERING FOR ELECTRIC CURRENTS. E. Oxley, Washington, D. C., 588,170. Filed June 19, 1897.
Consists in connecting with each of a series of consumers' circuits a series of metering mechanisms and controlling their operation from the central station.

Miscellaneous:—

TREATMENT OF PHOSPHATES. G. De. Chalmot, Leaksvillè, N. C., 588,266. Filed Dec. 20, 1895.
Consists of fusing the phosphate in an electric furnace, removing the molten phosphate from the furnace into contact with silica, and then while still hot dropping it into water.

ELECTRIC FURNACE. G. De Chalmot, Leaksville, N. C., 588,267. Filed Dec. 24, 1895.
Embodies an overflow opening combined with a revolving part arranged beneath it to receive the overflowing material.

ELECTROLYTIC PROCESS AND APPARATUS THEREFOR. C. Kellner, Vienna, Austria-Hungary, 588,276. Filed Feb. 24, 1896.
A process adapted for the decomposition of compounds whose electropositive constituent will form an amalgam with mercury.

TROLLEY BICYCLE. R. T. Oney, Charleston, W. Va., 588,465. Filed Sept. 10, 1896.
Employs a trolley adapted to carry the supply and return conductor, and driving mechanism geared to the wheel of the bicycle.

ELECTRIC HERB PAD. A. Roedel, New York, 588,479. Filed June 10, 1897.
A bag containing herbs and metal plates, adapted to set up a current by galvanic action.

APPARATUS FOR TREATMENT OF DISEASES. H. Sanche, Detroit, Mich., 588,483. Filed May 29, 1890.
Details of construction.

ELECTROLYTIC APPARATUS. E. Balbach, Jr., Newark, N. J., 588,524. Filed July 2, 1896.
Embodies a removable anode suspended in the tank.

MEANS FOR LOCKING ELEVATOR CONTROLLERS. Thomas G. Turner, New York, N. Y., 588,540. Filed Nov. 30, 1895.
Employs a fluid check to operate the stopping and starting mechanism when the door is open and the car is at a standstill.

ELECTRIC FIRE ENGINE. George W. Cox, Stuart, Iowa, 588,399. Filed Dec. 30, 1895.
Embodies an electric motor and a rotary pump on the same shaft.

Railways and Appliances:—

ELECTRIC TROLLEY DEVICE. S. Harris, Johnstown, Pa., 588,144. Filed Dec. 3, 1896.
The trolley wheel is mounted on a transverse shaft to permit of longitudinal motion.

ELECTRIC TROLLEY DEVICE AND CONDUCTOR CONSTRUCTION THEREFOR. S. Harris, Johnstown, Pa., 588,145. Filed Jan. 20, 1897.
Employs a relatively large contact wheel adapted to compensate for lateral variations in the conductor by turning on its own axis.

ELECTRICAL RAILWAY SYSTEM. W. B. Purvis, Philadelphia, Pa., 588,176. Filed June 29, 1896.
A sectional conduit system in which the contact is made by depressing a pin within the conduit by means of a flexible strip carried by the car.

ELECTRIC CONTACT DEVICE. D. S. Shallenberger, Johnstown, Pa., 588,188. Filed Jan. 30, 1897.
Similar to No. 588,144.

ELECTRIC RAILWAY SYSTEM. J. Claret & O. Vuilleumier, Paris, France, 588,396. Filed Aug. 4, 1896.
Distribution for electric railways. Details of construction.

RAIL BOND FOR ELECTRIC RAILROADS. V. E. Hunter, Cleburne, Tex., 588,435. Filed June 24, 1897.
A copper band adapted to be fastened to the rail by means of a bolt, around which it is wound once.

TROLLEY. F. Krabal, Pittsburg, Pa., 588,448. Filed Aug. 22, 1896.
Embodies guards movable laterally and extending above the trolley wheel and across the conductor.

TROLLEY. G. W. Sell, Jr., Johnstown, Pa., 588,488. Filed March 11, 1897.
Consists of a globular bearing, a wheel and cups carried by the wheel and adapted to embrace the bearing.

ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 588,528. Filed July 19, 1896.
Employs accumulators to store the surplus current taken by the car.

CURRENT CONDUCTING RAIL FOR ELECTRIC RAILWAYS. L. E. Walkins, Springfield, Mass., 588,541. Filed May 21, 1897.
Comprises a body of iron or steel having its tread side covered with a layer of copper.

ELECTRIC MOTOR CAR TRUCK. G. M. and J. A. Brill, Philadelphia, Pa., 588,391. Filed March 25, 1890.
Embodies a cross bar constituting a holder for the motor and resting on its truck bars with springs interposed.

Regulations:

AUTOMATIC RHEOSTAT CONTROLLER. R. Wilson, Louisville, Ky., 588,306. Filed May 29, 1897.
Designed for operating electric elevators and hoists.

Switches, Cut-Outs, Etc.:—

PROTECTIVE APPLIANCE FOR ELECTRICAL APPARATUS. A. S. Williams, Newton, Mass., 588,206. Filed May 7, 1897.
Consists of a thimble provided with a heating coil at one end, an insulating pin extending from the opposite end through the coil, and a tube concentric with and soldered to the bobbin of the coil.

LIGHTNING ARRESTER. C. C. Chesney, Pittsfield, Mass., 588,320. Filed May 14, 1897.
Comprises a series of concentric cylinders having flaring sides, the cylinders being spaced throughout their length, suitable insulated supporting means and circuit terminals therefor.

FLUSH SWITCH. L. Heck, Newark, N. J., 588,428. Filed April 19, 1897.
Of the push button type.

MAGNETIC SWITCH LOCK. S. H. Short, Cleveland, Ohio, 588,489. Filed Dec. 22, 1896.
Details of construction.

FUSE BLOCK. H. A. Sinclair, Brooklyn, N. Y., 588,536. Filed March 9, 1897.
The contact pieces are joined together in pairs.

Telegraphs:—

RECORDING INSTRUMENT. W. Thomson, Largs, Scotland, 588,251. Filed Oct. 2, 1896.
Comprises a marking point and paper and means for oscillating it to and from the marking point.

Telephones:—

SWITCHBOARD APPARATUS. W. F. Banks, Milford, Conn., 588,258. Filed Oct. 1, 1896.
Call signal system for telephone switchboards.

TRANSMITTER. A. Van Wagenen, Sioux City, Iowa, 588,511. Filed April 30, 1896.
Designed for use in automatic telephone exchange systems.

WHO OR WHICH?

A Jamaica, West Indies, newspaper has the following: Our Newport correspondent writes: "A sad fatality happened at Rose Hill on Saturday morning last, the 31st ult. Mr. J. Swaby (formerly a teacher at Broughton) mounted his mule and joined two or three others, intending to proceed to some pasture to look after stock there. A vivid flash of lightning struck the group and both Mr. Swaby and his mule were struck dead on the spot. His companions were terror-stricken and could only gaze in consternation at their late friend. The remains passed through Newport on Sunday morning, followed by several buggies (for he was universally respected) on its way to Ebenezer Church, where they were interred."

MR. F. E. BRINER, a well known electrician in St. Louis, writes: "Have been a subscriber for several years and can't be without it."

TRADE NOTES & NOVELTIES

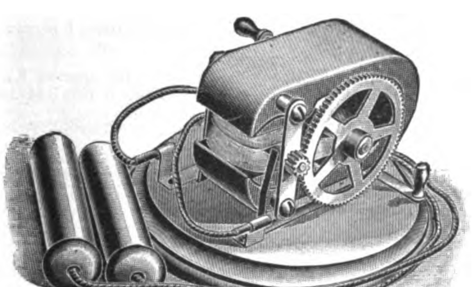
C & C SUCCESS.

The C & C Co. a number of years ago installed in the printing house of the American Bible Society an electric power transmission system, in which their bi-polar motors and dynamos were used. Among the directors of the company was Mr. John N. Stearns, Sr., head of the firm of John N. Stearns & Co., operating large silk mills in New York City, Williamsport, Pa., and Petersburg, Va. The machinery installed in the Bible House was so very satisfactory that it appealed at once to Mr. Stearns, with the result that a month ago that gentleman ordered a 40 kilowatt C & C multipolar generator for lighting their Williamsport mill, without the formality of receiving quotations from other manufacturers. This was followed later by an order from the same company for their Petersburg, Va., mill, covering one of the largest and most complete isolated power transmission plants in the United States, consisting of three multipolar generators, one 120 kilowatt and two 100 kilowatt, and 11 motors, three of 50 horse-power, one 45 horse-power, one 25 horse-power, one 18 horse-power, two 16 horse-power, one 15 horse-power, one 6 horse-power and one 3 horse-power.

This seems to carry out the old adage that first impressions are lasting, and the company is to be congratulated upon the very favorable opinion created some years ago, since which time there have been many changes in electrical apparatus. The reputation of the company for building economical and safe apparatus has been steadily growing.

"THE BABY DYNAMO."

UNDER this appellation, the Rhode Island Telephone and Electric Company, of 24 Calender street, Providence, are putting on the market the little magneto machine of which an illustration is here shown. If the switch is thrown out of contact with the multiplying gear, the current is mild, and its



R. I. TELEPHONE AND ELECTRIC CO.'S MOTOR.

strength is greatly increased if the switch is placed in contact with the gear. The retail price of the toy is $1, and with it a great deal of innocent amusement and instruction can be secured.

FRANKLIN H. KALBFLEISCH.

Those who are installing electric plants realize more than all others the importance of having acids and chemicals that will be reliable in every instance and will give satisfactory service. Those who desire such goods we take pleasure in referring to Franklin H. Kalbfleisch Company, 54 Maiden lane and 29 and 31 Liberty street, New York, whose advertisement appears in this issue. This concern have a wide reputation among electrical workers, and in many instances their acids and chemicals are specified in estimates, etc., which proves that they have a high reputation. The president of the company is Mr. Franklin H. Kalbfleisch, the youngest son of the late Martin Kalbfleisch, formerly mayor of Brooklyn, who was the founder of the firm to which the sons succeeded, first as Martin Kalbfleisch & Sons, and afterward as Martin Kalbfleisch Sons Company. Mr. Franklin H. Kalbfleisch withdrew from the above firm in March, 1893, and was the last of the original Kalbfleisch interest to sever his connection with the then existing corporation. The success that has followed the corporation has been marked. Under the most adverse circumstances and during the period of business depression and financial difficulties unequaled, the business has grown to enormous proportions and it was found necessary in March, 1896, to enlarge its factory capacity by acquiring the plants of the Joseph Binns Chemical Company, both at Brooklyn, N. Y., and Waterbury, Conn.

The company are now among the largest manufacturers of nitric, muriatic and sulphuric (brimstone) acids in the country, besides making a full line of acids for the various storage batteries, also battery and electropoin fluids, blue vitriol, etc. A prompt reply will be received to any inquiry for quotations.

NEW RAILS FOR THE B. & O.

The new 85-pound steel rails that the receivers of the B. & O. purchased several months ago, at an exceedingly low figure, are now being delivered at the rate of 5,000 tons a month. As fast at it comes it is being laid, and if the weather continues good, at least 20,000 tons of it will be in the track by Christmas. Nearly a million cross-ties have been bought in the last year and placed in the track ready for the new rail. Ballast trains have been kept busy up and down the line and the work has progressed with such rapidity that when the new rail is down, the tracks will practically be brand new from Wheeling to Baltimore. There are lots of good rail in the old tracks, not heavy enough for the new motive power, which will be taken up and laid on divisions where traffic is not as great as it is on the main line. About 10,000 tons of new steel will be laid on the lines west of the Ohio River this fall, if weather permits.

ADVERTISERS' HINTS

WARD LEONARD ELECTRIC COMPANY have recently issued a new catalogue showing new types of rheostats, circuit breakers, etc., and including new prices. A copy will be sent on application.

WALKER COMPANY present an argument in their advertisement in favor of using 2½ watt lamps provided a steady regulation in the dynamo is secured, which will prevent the lamps from breaking easily. The use of a 2½ watt lamp instead of a 4 watt lamp will permit either a greater illumination with the same number of pounds of coal or by not increasing the number of lights will effect a saving in the coal bill.

GOUBERT MANUFACTURING COMPANY, manufacturer of the Goubert feed water heater and Stratton Separator Company, not only have their apparatus in the plant of the Charleston City Railway Company, described in this issue, but have also installed it in a number of street railway companies in various parts of the country.

DIEHL MANUFACTURING COMPANY show in their advertisement an illustration of their exhaust wheel.

ON PAGE XX. will be found several announcements offering advantageous properties for sale, and also showing apparatus desired by various advertisers.

ELECTRIC APPLIANCE COMPANY speak this week of the merit of Paranite wire.

E. G. BERNARD COMPANY have established a Western agency in the Monadnock Building, Chicago, Ill.

AMERICAN ENGINE COMPANY have recently furnished the United States War Department with an American Ball engine and a 35 kilowatt d. c. generator.

E. AND O. E. NOT O BUT E. By a slight error in our issue of August 19 the address of the Monson-Burmah Slate Company was given as Portland, Mo., instead of Portland, Me. This mistake has been corrected this week, and electrical concerns who wish to purchase slate for various electrical purposes might communicate with this company.

AMERICAN RHEOSTAT COMPANY announce that although wheat and other commodities have gone up, their prices are still the same, and that they manufacture rheostats for all purposes. They also invite prospective purchasers to write for price lists of their goods.

THE BALL ENGINE COMPANY, ERIE, PA., write: The J. S. Monken Company, Memphis, Tenn., in a letter to us ordering a crank pin box for a 60 h. p. engine, say that this is the first repair part ordered since the installation of the engine ten years ago. This substantiates our claim, which we can verify by other instances, that a well built high speed engine has as long a life with greater freedom from repairs than a slow speed engine.

NEW YORK NOTES.

EDISON MANUFACTURING COMPANY, 110 East Twenty-third street, New York, have just issued a new and exhaustive catalogue of their numerous specialties, such as Edison-Lalande batteries, Edison motors and fan outfits, Edison projecting kinetoscopes, Edison electromedical appliances, etc. This concern can special attention to their full line of Edison X-ray apparatus for battery and 110 volt direct current outfit; also combination X-ray and cautery outfit for same current. The Edison Manufacturing Company will be pleased to send their catalogue to any address upon application.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, carry a large line of felts for electrical purposes and are pushing this department. They solicit correspondence from consumers of these goods, as well as in their other lines, such as tools for electrical purposes and telephone box locks.

WESTERN ELECTRIC COMPANY are now occupying their fine new factory on Bethune street, New York City, but will carry on still their retail store in the old Thames street building, where a good deal of work is also being done by this busy concern.

MR. R. F. STRAINE and Mr. C. S. Lamson, the president and treasurer of the United Telegram Company, were arrested in Boston on August 30, on a charge of conspiring to defraud the company to the amount of $73,371. The action was taken on the initiative of W. H. Baker, vice-president of the Postal Telegraph Company. Mr. Marsden J. Perry is the receiver of the United Telegram Company.

MR. J. H. ASTRUCK, manager of the Electric Arc Light Company, 687 Broadway, New York City, says: "With the return of prosperity throughout the country, we find that the electric lighting business is improving daily, and, in addition to a large amount of smaller orders, we have within the last month secured some large installations. We have just closed a contract to light the stores of Messrs. James A. Hearn & Son, of West Fourteenth street, New York City, with 135 or more 'Pioneer' lamps."

T. N. MOTLEY & CO., 43 John street, New York, have added an electrical department to their business, for all lines of work. It is in charge of Mr. Joseph Keefe, lately with the Westinghouse and Greeley companies.

A. L. BOGART have removed their business in electric gas apparatus, etc., from Union Square to 50 East Twentieth street, New York City, and are now installed in their new quarters.

BRAZING GRAPHITE.—Not a little of the expense in brazing is due to the cost of removing the brass which has stuck to the metal where it is not wanted. The removal of this brass is usually attained only by patience and diligent filing. Now comes to the aid of the brazier that unique mineral, graphite, which is not affected by acids, alkalies, heat or cold. Braziers who have made use of Dixon's Pure Flour of Graphite pronounce it worth its weight in gold. A sample will be sent without charge by the Joseph Dixon Crucible Company, Jersey City, N. J., who are the only manufacturers.

CHAS. J. BOGUE, Centre street, has added a new department to his general line of repair work. It is the manufacturing of searchlights, projectors, and as a specialty, searchlights for the tops of trolley cars; also projecting lamps for electric fountains.

WESTERN NOTES

MR. M. L. VOUGHT, of La Crosse, Wis., has recently placed upon the market an adjustable hanger for incandescent lamps, which seems to be destined to fill a long-felt want in this direction. The hanger is sold at a very low price, and is having a large sale. The United States Electrical Supply Company, of 120 Liberty street, are the Eastern sales agents.

GALE'S COMMUTATOR COMPOUND.—The price of Gale's Commutator Compound from and after September 1 will be reduced one-third. Speaking of this reduction, Mr. Isaacs, secretary of K. McLennan & Co., stated to a representative of this journal, that there would be no reduction in quantity or quality, but in price alone. There are several reasons for this reduction, he stated, chiefly the more than treble former sales. The adoption of Gale's commutator compound by nearly every electrical power plant and central station, and by a vast number of isolated plants, has more to do with the reduction than any one other cause; as, in fact, it has made possible the other reasons, that of improved new machinery and direct importation of ingredients. The latter will result in large saving, and they propose to give the users of Gale's compound the benefit of what they buy, over increased use made possible. The reduced price will prevail for all supply houses, and free sample sticks will still be furnished to the few, if any, who have not as yet tried Gale's.

MR. GODFREY G. LUTHY, of the Royal Electric Company, Peoria, Ill., made a short visit to Chicago a few days ago.

VOL. XXIV. SEPTEMBER 9, 1897. No. 488.

TELEPHONY AND TELEGRAPHY

THE HARTFORD, CONN., EXCHANGE OF THE SOUTHERN NEW ENGLAND TELEPHONE CO.

THE constant evolution and improvement in method and equipment of the telephone industry, is probably not excelled by that of any other of the great electrical enterprises. Certainly the material of no industry of like age has undergone so great a change or has been the subject of so varied and exhaustive experiment as that which was instituted upon the invention of the telephone. From the days of the "buzz-box" to the present time, when we converse, without thought of distance, with people scattered from Maine to Nebraska, capital, brains and the energy of thousands have been united in a persistent and successful endeavor to develop the science, and place it upon an efficient footing. The history of the business has been one constant, unceasing effort to develop

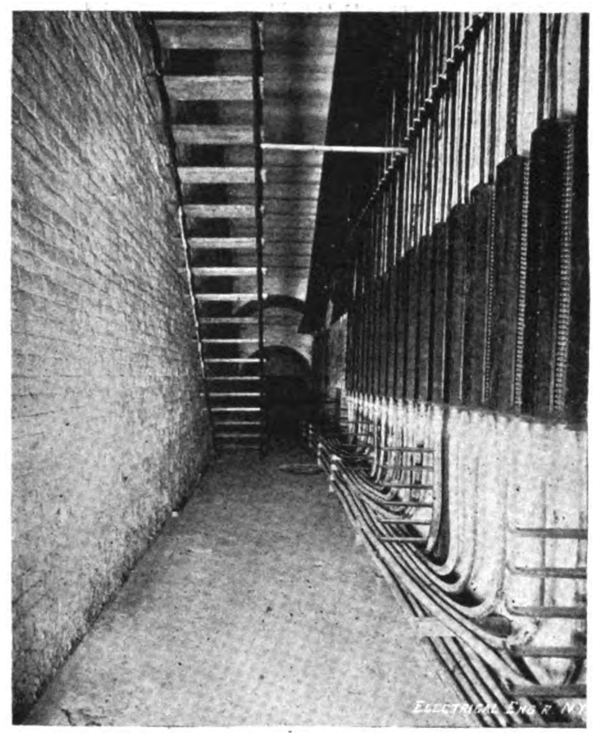
HARTFORD, CONN., TELEPHONE EXCHANGE.

and perfect. There has been no chance and no excuse for a wideawake management to get into a rut.

Among the companies which have led rather than followed, in this march of improvement, is the Southern New England Telephone Company, whose New Haven Exchange, instituted on January 28, 1878, is conceded to have been the first telephone exchange in the world. Next in size and importance to the New Haven Exchange of the Southern New England Company, ranks that located in the City of Hartford. This exchange numbers 1,200 subscribers, and has its headquarters, under the management of William H. Babcock, an old-time telegrapher, in the company's building, erected for the purpose, on Pearl street.

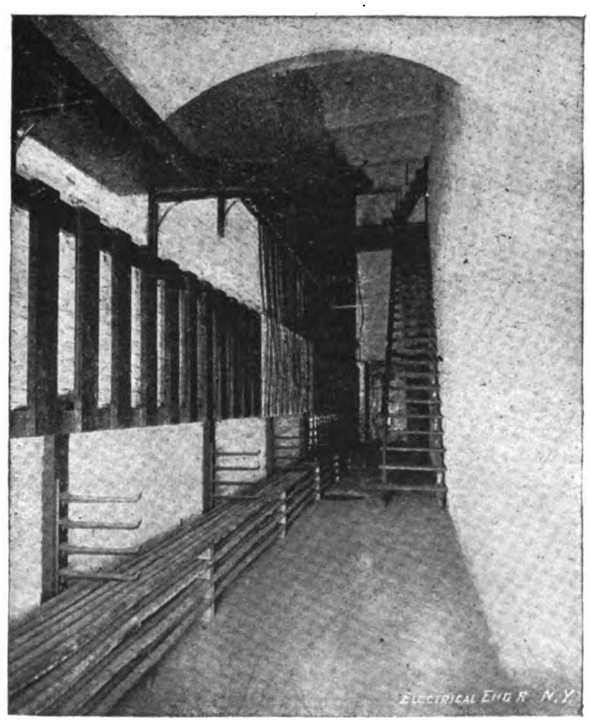
A system of underground distribution is being rapidly pushed in Hartford. At the present time it comprises 41 miles of underground duct, containing 25 miles of cable. The system in use is one originated by General Superintendent E. B. Baker, of the Southern New England Company, and is giving good results. It consists of manholes at each street corner, with regular cable ducts of 3-inch cement-lined pipe laid between them, with a distribution pipe superimposed on them. In this duct, at intervals of 25 to 50 feet, are inserted iron junction boxes, from which are run 1½-inch iron curb laterals, which terminate in curb boxes under the sidewalk. From these curb boxes, an ordinary iron gas pipe is run to a point just inside the cellar wall of the subscriber.

Service wires are run from the nearest manhole, where the regular cable ends in an okonite tip, to the subscriber's premises through the distribution duct, junction box, curb lateral



HARTFORD TELEPHONE EXCHANGE TUNNEL.—LOOKING OUTWARD.

and service pipe, one pair being used for each subscriber regardless of whether the service is single or party. The accompanying diagram gives a clear idea of the system. From the

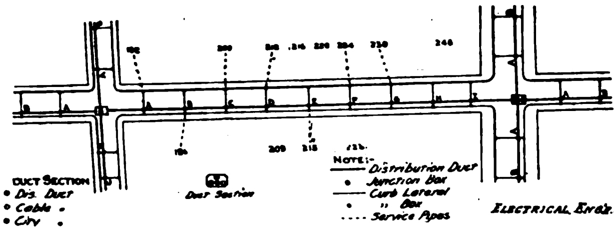


HARTFORD TELEPHONE EXCHANGE TUNNEL.—LOOKING INWARD.

office manhole, on Pearl street, the forty 52 pair cables in use enter the building. These contain 2,180 metallic circuits, the system in use all through the territory of the company. From

the front wall of the building, the tunnel, the views of which are shown on page 221, carries the cables to the terminals.

The underground cable heads in the tunnel are connected with the main distributing rack by means of rubber-covered cables. The distributing rack itself is made entirely of iron; the switchboard cables terminating on the front side and the rubber covered cables above mentioned, on the back. The



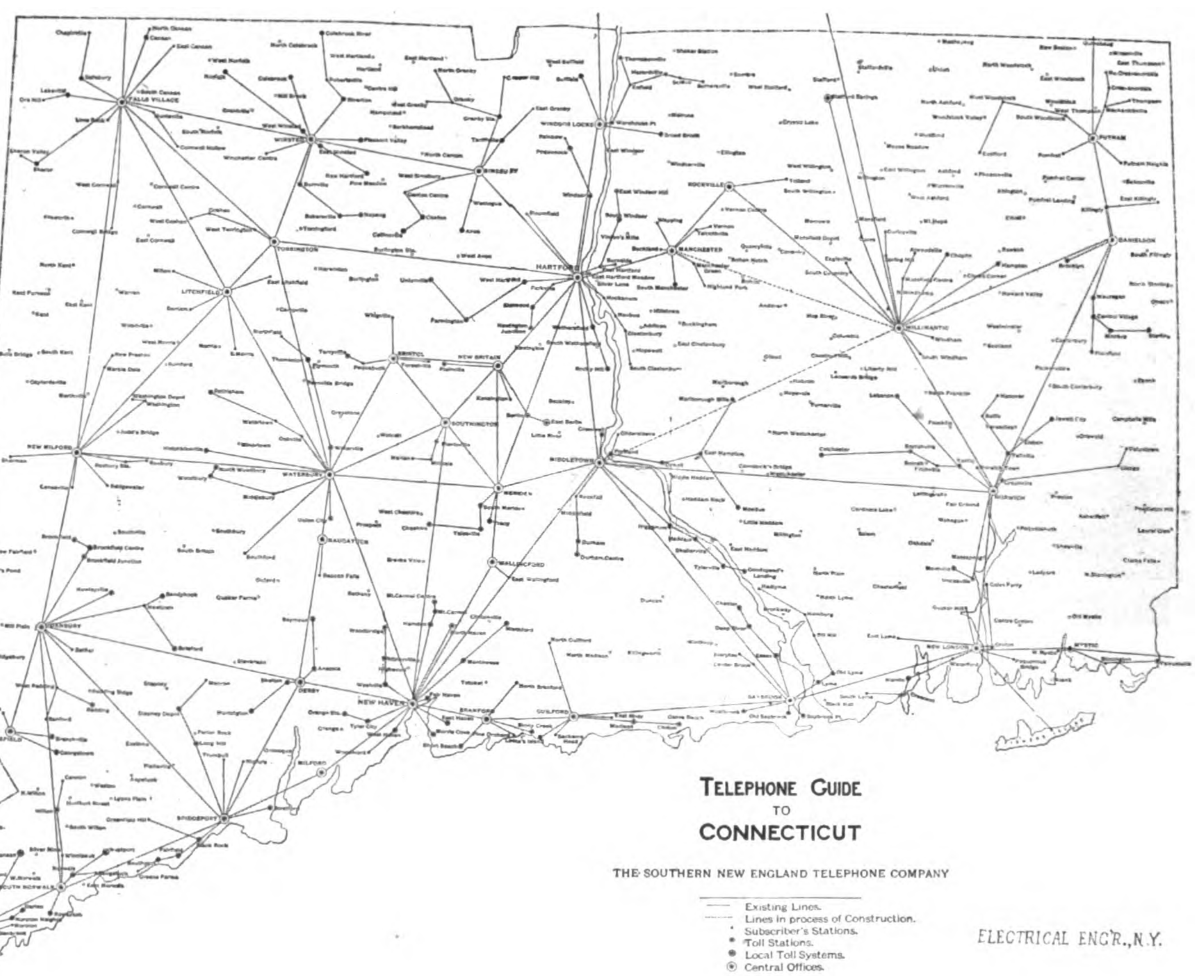
SYSTEM OF UNDERGROUND TELEPHONE LINE DISTRIBUTION, HARTFORD, CONN.

cross connecting between these cables is done with okonite wire twisted in pairs.

The protectors are mounted on the front side of the rack, and are so arranged that they are in series between the okonite wire and the switchboard cables. They consist of a carbon plate lightning arrester and a small heating coil, which, upon the passage of any abnormal current, automatically grounds

multiples through every section. It is composed of eight full sections and two one-third sections, half of it being placed on one side of the room and the balance on the other side, so that the operators sit back to back, the chief operator's desk being located midway between them. Six of these sections are equipped for two long distance, four trunk and twelve local operators; one is used for a test section and the eighth is at present unequipped. Each trunk and long distance operator's position is equipped with twenty line annunciators and ten pair of cords. The local operators' positions are each equipped for eighty lines, and the same number of cords as are on the trunk and long distance sections. There is a small electric light in front of each operator, so connected that it glows as soon as an annunciator in that position falls. Upon answering the call the operator automatically restores the drop to its normal position and extinguishes the light. She also throws a busy test upon the wire so that the other operators all know that it is in use.

The first section of the switchboard is equipped entirely with four point jacks, so arranged that when plugs are inserted in them all the rest of the switchboard is cut off. Daily tests are made at this section on all of the local wires for grounds, crosses or open circuits. This section is also used for a recording trunk operator, who receives all calls for State and Long Distance connections, finds out from the party calling the name and location of the subscriber who is wanted, and in the case of a firm or a corporation, the particular party desired. This information is all placed on a message ticket, which is turned over to the operator having under her control



MAP OF CONNECTICUT, SHOWING CITIES AND TOWNS REACHED BY LINES OF THE SOUTHERN NEW ENGLAND TELEPHONE COMPANY.

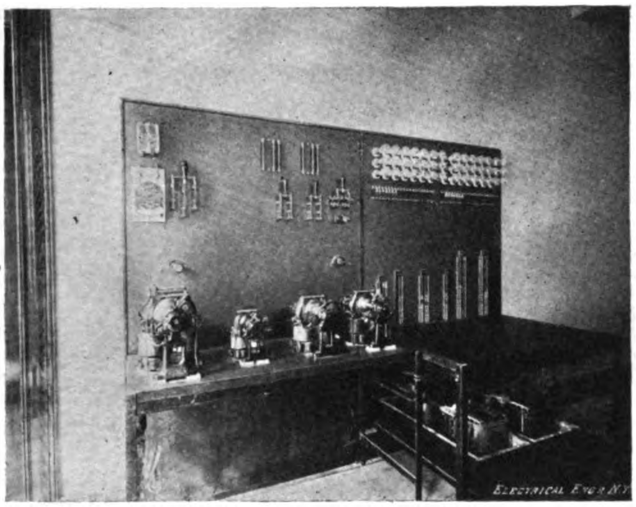
the wire and in this way cuts off the switchboard. These heating coils also act in connection with the fuses at the further end of the underground cables; that is, when they ground a wire at the central office they put a practical short circuit on it, and the rush of current which immediately follows blows the fuse at the cable terminal and so opens the wire.

The local switchboard was manufactured by the Western Electric Company. It is of the bridging metallic type with self-restoring drops, and is so arranged that each local wire

the circuits which reach the exchange desired. She, from this information gets the party wanted, and when he is reached calls the subscriber and makes the necessary connection.

All the trunk wires pass from the cross connecting rack directly to an independent trunk test-board located back of the chief operator's desk. This test board consists of a combination telegraph peg switchboard and telephone looping-in and terminal jacks. Each trunk wire passes through two of these looping-in jacks, then through the metal strip on the

peg switchboard and from there to a terminal jack where they are left open. The peg switchboard and looping-in jacks are used for testing the wires, that is, they are so arranged that any of the various test batteries may be thrown on any wire and a Morse relay and key looped in on the circuit. Each annunciator on the telephone trunk switchboard is connected with two flexible cords on the test-board, these cords termin-



Hartford Telephone Exchange.—Power Switchboard and Generators.

ating in single plugs. By means of this arrangement any pair of trunk wires can be thrown into any one of the trunk operator's positions, and in the case of a breakdown the wires can be made up in any way desired by the chief operator without his being obliged to go anywhere near the telephone switchboard.

The power-board is built entirely of slate and iron and is equipped with four Crocker-Wheeler dynamotors. Two of these machines are so wound that they give on the secondary side a 75-volt alternating current; one of them is used for ringing subscribers' bells and the other is a relief machine for the same purpose. The third machine gives a 110-volt direct current on the secondary side, which is used for Morse

Hartford Telephone Exchange Switchboard.

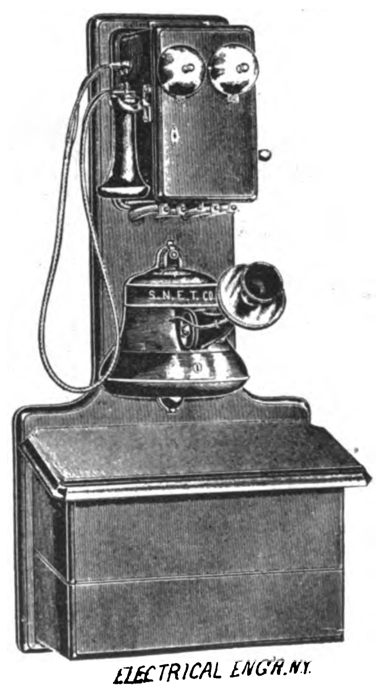
work or for testing as is necessary. The fourth machine gives a 6-volt direct current which is used for charging four cells of storage battery. From these four cells is drawn the current for all the operators' transmitters, the busy test, restoring the drops and lighting the lamps above mentioned. They are so arranged that they are always in circuit. The charging is done whenever necessary.

In connection with their telephone service the Southern New England Telephone Company have introduced Watchman and Standard time systems. The former is designed to give banks and factories a better hold upon their night watchmen than is furnished by the ordinary watchman's clock. It consists of an open circuit district box located at the subscriber's station; one side of this box is connected with the ground and the other side is connected to one side of their telephone circuit. The same side of the telephone circuit passes through a switch at the telephone exchange, so that a Morse relay and grounded battery can be tapped onto it. The local points of this relay pass through a Game-

Hartford Telephone Exchange Switchboard.

well fire alarm register and time stamp. This register records automatically on a paper tape the number of the calling box and the time the call is received. In case a watchman does not send in his call at the proper time it shows positively that he is either not attending to his duties or is detained from doing so. In either case the police are notified by telephone by the person in the exchange who has this system under his supervision, and they look the matter up.

The Baker standard time system consists of self-winding clocks located in the subscribers' stations, which are syn-



Subscriber's Telephone Set.

chronized every twelve hours by time signals received from the Yale College observatory in New Haven. These clocks are connected with the telephone circuit at the subscribers' stations and the telephone wire is used to send the impulses of current which synchronize them.

The clocks are so arranged that the telephone circuit is grounded through the synchronizing magnets for about three minutes every twelve hours; one and one-half minutes before

and one and one-half minutes after the even hour. During this period, at exactly the even hour, an impulse from a grounded battery is thrown on the telephone circuit by the master clock. This battery energizes the synchronizing magnets and sets the clock if it is either fast or slow. The clock is synchronized at hours when the telephone circuit is not liable to be in use for telephonic messages, for instance, at 7 a. m., and 7 p. m., although even if the subscriber does happen to be talking at the time, there is no practical interference to the telephone service.

ELECTRIC LIGHTING

THE CROYDON, ENGLAND, ELECTRIC LIGHT PLANT.

THE electric lighting of the town of Croydon, England, practically a populous suburb of London, is vested in the hands of the municipality, but in the operation of the plant an ingenious, though temporary, method of compromise has been adopted, interesting in its novelty, and unique in that it differs from any other case known to us of municipal ownership of an electrical lighting plant. In the system of severation and distribution there is also considerable that is novel.

The funds for the erection of the station and the underground supply system were all provided by the corporation, which purchased the plant in its entirety from the British Thomson-Houston Company, Limited. This latter company agreed to operate the plant for ten years, paying to the town authorities 3 per cent. interest on the investment, and contributing a certain annual per cent. to the sinking fund. On the other hand, the British Thomson-Houston Company exploits the system and collects all revenue from the sale of light and power, etc. The agreement stipulates that at the end of ten years the installation shall revert to the municipality. This period may be shortened on six months' notice to the company, and the payment of an indemnity calculated on a basis previously agreed to.

The system of generation is high tension alternating at 2,000 volts for the incandescent lighting; this is directly transformed down in substations. For the arc lighting rectified

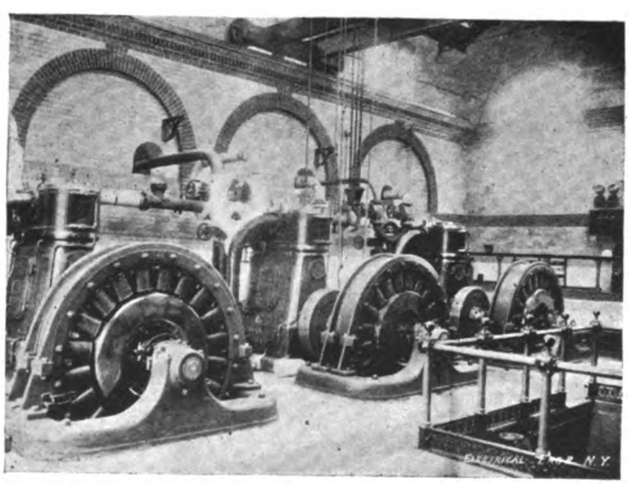


Fig. 1.—Dynamo Room, Croydon, Eng., Electric Light Plant.

alternating current is used. During the evening current is furnished from the main alternators; during the daytime from a smaller alternator driven by a continuous current motor operated from a storage battery, charged during the evening by the same combination, the position and operation of the two machines, however, being reversed. By the adoption of this method a direct and noticeable economy is effected. The services of boiler, engine and alternator as well as that of the necessary workmen and attendants during the day are dispensed with. For so small a demand as at present exists for daylight current, the charges for this extra service would be very heavy, but by the unique method adopted a single attendant suffices to look after the station during the day, and to keep watch over the small generator group and the battery.

This is the first instance in which this system has been followed, and its simplicity is such that, in England especially, the example is likely to be extensively followed, in cases where the day load is not sufficiently great to warrant the operation of an entire steam and electrical group.

The central station outside the town is a brick building,

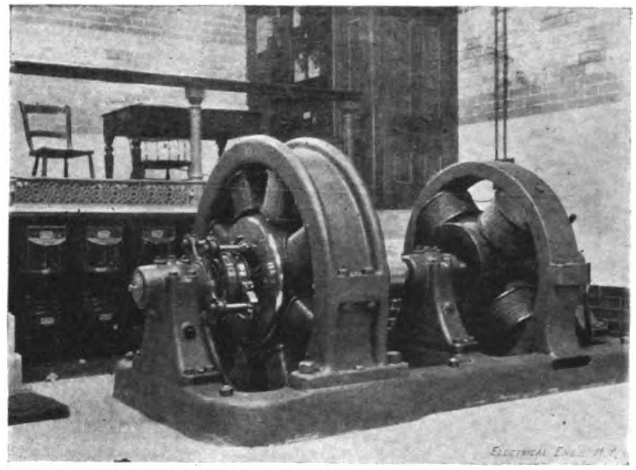

Fig. 2.—Combination Set, Croydon Electric Light Plant.

containing boiler room, engine room and battery room and offices. The boiler room contains three multitubular boilers, each of 300 horse-power capacity at 160 pounds pressure; two Worthington pumps and a Green economizer. All the steam piping is in duplicate to avoid shut down in case of accident. The three engines illustrated in Fig. 1, are of the Belliss compound vertical type, each with a capacity of 240 horse-power, at a speed of 300 revolutions per minute. Each engine is provided with a special governor which allows the load to vary from full to no load, without increasing the speed more than five revolutions per minute. To each engine connected by a special clutch is a Thomson-Houston alternator especially designed to meet the conditions of this installation. The machines are 20-pole 60-period alternators, the armatures of which carry each coil in an independent slot in the core, so that in case of injury to any coil it is confined to that coil and does not affect its neighbors. As the coils are wound in forms before placing in the case, injured ones can readily be removed in case of accident and be replaced by new ones. Of the collector rings and brushes, one set is thoroughly insulated, while the other is connected to the earth. The insulated ring and brush are under a glass cover to prevent accidental contact. Each alternator is rated at 120 kilowatts at 2,000 volts.

For the services of the station during the day the motor generator group, above referred to and shown in Fig. 2, is called into requisition. The group consists of a shunt-wound direct-current motor, directly coupled to a 30 kilowatt alternator. The motor during the night becomes a generator, driven by the alternator as a synchronous motor, and furnishing current to the storage battery. During the day this action is reversed; the direct current machine again becomes a motor, taking its driving current from the storage battery, and drives the alternator which reverts to its original purpose as a generator. The storage battery is divided into two parts, each consisting of 60 cells, occupying a room to itself adjoining the engine room. Its current not only drives the combination just mentioned, but also furnishes the exciting current to the main alternators. The cells are charged at 160 volts and discharged at 120 volts. A 3-volt dynamo, driven by a small motor, is used in the treatment of any "sick" plates in the battery.

The main switchboard in the station is simple in character. As the exterior conductor of the concentric cable used is connected to the earth, both switches and cut-outs are single pole. A Thomson recording wattmeter is in circuit with each alternator and Kelvin station instruments are used.

The substations are four in number, each connected to the station by independent feeders, but interconnected also by high tension cables. Each feeder supplies its own portion of the system, but at the junction points are placed boxes, which allow any section to be connected to its neighbor in case of accident to any substation. Three of the substations are in small

brick houses; the fourth is underground in a well cemented and well ventilated chamber.

Each substation contains the transformers and two switchboards, one for the feeders and distribution switches, the other for the interconnecting switches and distributing mains. All the lines are fully protected by circuit breakers and fuses. The mains are all laid underground, and all cables used are concentric. The secondary distribution is made at 200 volts.

The purely municipal lighting is effected with 43 T.-H. arc lamps, 20 of which operate until midnight only, while 23 burn for eighteen hours.

THE METERS OF TO-DAY.[1]

BY R. F. SCHUCHARDT.

MR. GEORGE H. JONES, of Fond du Lac, and myself have just completed a thesis on American electricity meters under Prof. D. C. Jackson, at the University of Wisconsin. The meters tested were the Thomson, Duncan, Shallenberger and Schaeffer.

The results obtained in our investigations show that the meters of the present day are not all that might be desired, and central station men, who know that the bills of customers using approximately equal amounts of light often vary to a great extent, and who continually have complaints of overcharges made to their companies, will bear me out in this. It is of the utmost importance that central station men test each meter they install. Many managers are beginning to realize the importance of this subject, and have added meter-testing departments to their stations, where all meters are tested before they are installed. After they are once installed they should be inspected every six months or so, in order to see that they are working properly. This is hardly ever done at present.

The curves of the tests illustrate very clearly the action of these meters. Our method of calculating the error of the meter may be of interest. The speed of the meter is directly proportional to the load; therefore, for a given load the product of seconds per revolution of the armature and amperes (in ampere-hour meters), or watts (for watt-hour meters), equals a constant (which we call K), which varies with the make and size of meter. As will be seen this K is the time in seconds which it takes for the armature to make one complete revolution per unit of load (ampere or watt).

The product of the observed load and seconds per revolution divided by this K, $\frac{\text{amp. x sec.}}{\text{K}}$, or $\frac{\text{watts x sec.}}{\text{K}}$, should then equal unity for an accurate meter and the variation from unity will give directly the error. Should this quotient be more than unity, the meter runs too slowly on that load; and if less than unity, the error will be negative, which means that the meter is running too fast.

Thus, let the time per revolution be 4 seconds for a load of 440 watts on a 10-ampere, 100-volt Thomson wattmeter. The value of K for this meter is 1,800; then, $\frac{4 \times 440}{1,800} = .973$, which shows that the meter runs 2.2 per cent. too fast on that load. Or, let the time per revolution of the armature be 2 seconds for 3.3 amperes on a 20-ampere Shallenberger ampere-hour meter in which the value of K is 6.33; then $\frac{2 \times 3.3}{6.33}$ The meter is, therefore, 4.2 per cent. slow on that load.

The curves show that the action of the meters is very irregular, but their general behavior is clearly shown.

We found our samples of the Duncan watt-hour meters to run too fast, but by properly adjusting the magnets, their error could be brought within the limits of about 5 per cent. either side. Both of the Duncan ampere-hour meters tested started much too slowly and were also much too slow on the high loads. The effect of frequency is very marked, the difference in error at full load between frequencies of 60 and 130 being about 30 per cent.

After starting load, the Schaeffer wattmeter ran with a small and fairly uniform error. These meters are designed for frequencies, and when built for two frequencies are provided with a special German silver resistance in the pressure circuit to compensate for the difference. One of the meters tested by us, built for frequencies of 60 and 130, ran with an average difference of about 6 per cent. between these frequencies.

All of the new Thomson wattmeters started on no load, while the old ones started much too slowly. Their curve of error is a remarkably straight line after starting load. They are, of course, independent of frequency.

The Shallenberger ampere-hour meters started much too slowly. One of the three tested ran fairly uniform after starting, while the other two were too slow on high loads. The higher frequency makes them run from 5 to 15 per cent. faster.

The Shallenberger watt-hour meter was found to be very fair. It started on a very light load, ran without any great error, and responded promptly to changes of load. Frequency has no appreciable effect.

All of the meters tested are practically unaffected by the changes of pressure likely to occur in service. The Diamond wattmeter should not be used with inductive load, as the effect of such load is very marked, making the meter run much too slowly, and with a power factor low enough it stops entirely and even runs backward.

Besides these meters tested in the laboratory, we were enabled, through the courtesy of the Madison Gas and Electric Company, to test meters in actual service. The general results of this test indicate that the ampere-hour meters require a comparatively large current to start them; run much too slowly on starting load and on the higher loads. Most all of them have considerable error on overloads. The wattmeters are somewhat better, and as a rule run too fast on all loads except at starting and with a fairly uniform error. The Thomson meters show the least variation in error, but the continuous watts absorbed are more than in any of the others.

A fact of great importance brought out in this test is the lack of proper attention paid to the installation of the meter. In many cases the meters are placed on door frames where they are continually jarred. They should be installed by securely fastening them to a firm wall in a readily accessible dry place and well leveled. The meters should all be carefully sealed to prevent being tampered with. The seal should bear the private mark of the company, so any unauthorized inspection of the meter can be detected. The meter is a delicate piece of apparatus and should be carefully handled when being placed in position so as not to injure it.

After it is installed, it should be tested to be sure it is running correctly. Spiders and insects in general are very fond of the warm meters, and have many times helped to reduce the consumer's bill. The meter should, therefore, be dust-proof and be regularly inspected.

[1]Read before the Northwestern Elec. Assoc. Abstract.

MORE MONEY DESIRED FOR THE JACKSONVILLE, FLA. PLANT.

Chief Engineer John T. Parry, of the Jacksonville, Fla., city electric light plant, is agitating the question of the enlargement of the plant, and says: "I do not see how we expect to get along at all this winter with the present capacity. As it is we are trying to do too much business with our facilities. It is now of the greatest importance that the plant should be enlarged to a considerable extent.

"First, the building—especially at the west end—will have to be made larger by twenty or thirty feet in two directions. Another dynamo will have to be provided, and a third engine will become necessary. It will be difficult to add these impovements, and it will cost something in the neighborhood of $25,000 or $30,000 at the inside.

"The plant has always been a paying investment, not only to the city, but to the taxpayer and to the person burning the lights. In my opinion, taking in its value to the citizens, this plant has paid the total interest on the entire indebtedness incurred by bonding the city. It may not be shown in figures, in an estimation of the worth in dollars and cents, but in true benefit arising, first, from municipal ownership of a modern and complete plant, and, secondly, from the actual saving in cash by reducing the price of electric lighting of residences and places of business.

"It would be a capital idea to enlarge the plant so as to render the lights now in service of more benefit to the user. They are dim because of lack of current. It would also be a fine idea to put in a dynamo that could be run during the day for power purposes, and the entire extension would pay for itself.

"The city treasury seems to be wanting in funds, but sooner or later some provision for the increase so much needed will have to be made. As well have no municipal plant, if we cannot have one with sufficient capacity to accommodate the entire people if they want electric lights or power, and if they are willing to pay for them. A limited supply now does not meet the demands of the taxpayers, and these is some dissatisfaction—not with the quality but with the quantity."

ELECTRIC TRANSPORTATION

ELECTRICITY ON THE METROPOLITAN STREET RAILWAY IN KANSAS CITY.

BY JACQUE L. MORGAN

IN spite of the general business depression which has been so prevalent throughout the country, there has been expended in the two Kansas Cities in the past year for additions and improvements in street railways, about one million dollars. Transportation for the quarter million inhabitants of these cities is furnished by twenty-two street railway lines, twenty of which are owned and operated by the Metropolitan Street Railway Company, comprising nine cable, nine electric and two mule lines. The latter two roads are to be changed to trolley roads at once and the change will signal the final emancipation of this city from "black smoke" electromotive force."

The railroad company have made many improvements, a new line has been built, horse car lines transformed to trolley lines, tracks relaid and the entire system, cable and electric, incorporated into one net by the Falk cast joint. But by far the most interesting of all the improvements is the new central power house and its system of power distribution for the operation of electric and cable roads. This plant operates daily seventy-seven cars over fifty-five miles of trolley road, and ten cable trains over four and one-half miles of road.

The power house is located centrally with reference to distribution, on the west bank of the Kansas River, in Kansas City, Kan. The building is of brick and stone, with slate roof supported by steel girders. Its dimensions are 144 feet by 114 feet wide. It is divided into two rooms running the length of the building. One of these, the boiler room, is 51 feet wide and the other, the engine room, is 63 feet wide. In this room there is a 30-ton traveling electric crane, installed by the Brown Hoisting and Conveying Machine Company, of Cleveland, Ohio. This crane spans the room and runs the entire length of the building.

The boiler room contains six 250 h. p. Babcock & Wilcox boilers of the latest design and capable of carrying 200 pounds pressure. Provision for 1,600 additional horse-power has been made. The boilers are equipped with chain grate stokers, fed by gravity from a 1,000-ton coal hopper overhead, making the firing almost automatic and smokeless.

The economical handling of the fuel supply and of the ashes is deserving of special attention. From the car in the unloading shed the coal is shoveled by hand into receiving hoppers; then a conveyor carries it under the boiler room floor to the end elevator; thence to the coal hoppers overhead, where a horizontal conveyor distributes it throughout its length. The conveyor also carries the ashes from the ashpits into hoppers, where it is drawn by gravity into receiving cars.

In the engine room is a direct connected generator set of 2,000 h. p., with provisions for three similar sets, making a total of 8,000 h. p.

The engine is a Reynolds-Corliss compound condensing with

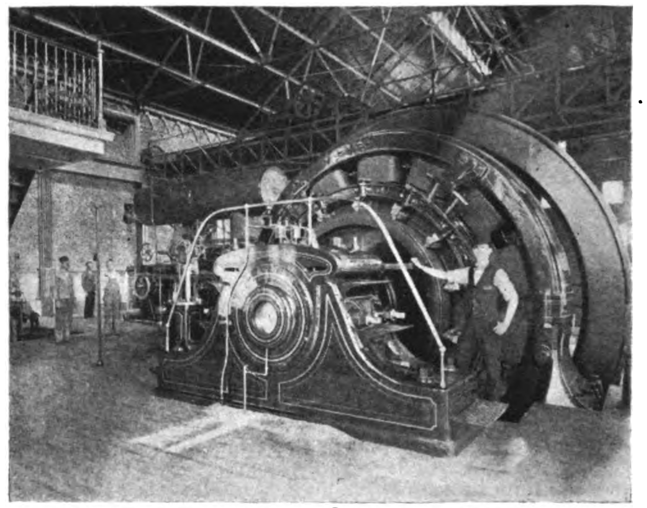

FIG. 1.—1,500 K. W. WALKER RAILWAY GENERATOR, KANSAS CITY RAILWAY CO.

cylinders 30 inches and 60 inches by 48 inches stroke. The flywheel is 20 feet in diameter and weighs 120,000 pounds. This revolves eighty times a minute on a 24-inch shaft. The engine is provided with a special governor, which is set five revolutions above speed. This effectually prevents the engine racing and wrecking itself and the building.

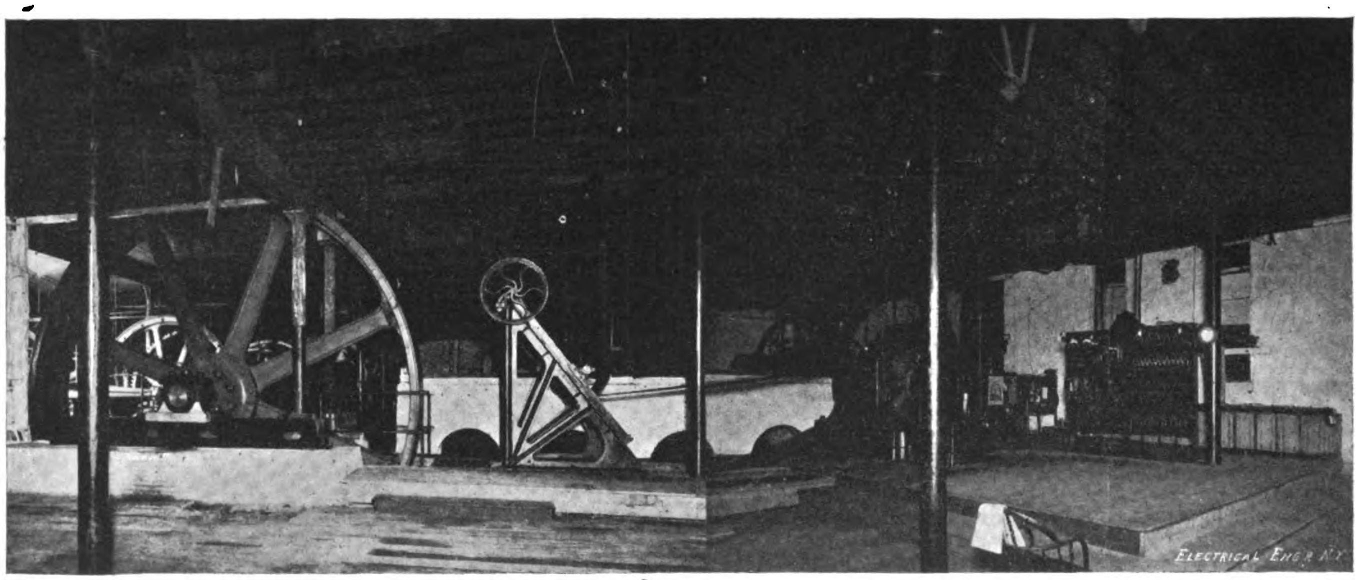

FIG. 2.—ELECTRIC MOTOR DRIVING CABLE MACHINERY, METROPOLITAN STREET RAILWAY, KANSAS CITY.

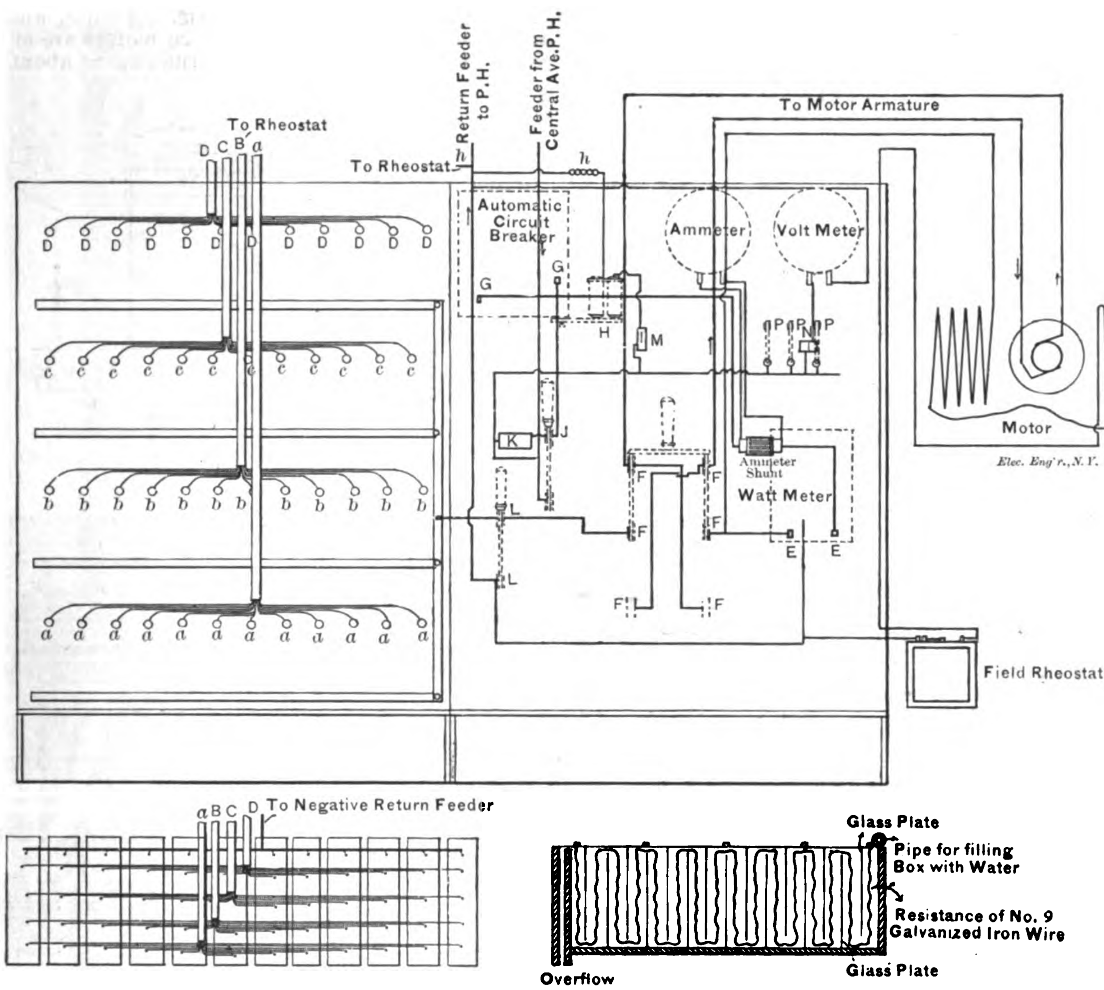
The generator, Fig. 1, is a fourteen pole, 1,500 k. w. Walker machine, and its 10½-foot armature is capable of inducing a current of 2,730 amperes at an e. m. f. of 550 volts. This dynamo is guaranteed to run at 50 per cent. overload for five hours. Up to the present time it has given great satisfaction, and although heavily overloaded not a spark of any character has been seen on the commutator.

From the dynamo three 800,000 cm. cables convey the current to the switchboard and through an 8,000 ampere Thomson recording wattmeter. The switchboard consists of two generator panels and twenty feeder panels. The switchboard is of the G. E. type and is in two tiers of polished slate panels. Weston instruments are in place on both generator and feeder panels. Each feeder panel has a shunt amperemeter, circuit breaker, quick break switch, and wattmeters will soon be placed.

The feeders running from the power house to the various lines, one of them 28,300 feet long, range from 300,000 to 1,000,000 cm. in area.

A one-million cm. circuit carries the current, a distance of about one and one-half miles, to the Washington street power house. Here a T.-H. dynamo, now doing duty as a motor, operates the Summit street cable line, and, although the amperemeter registers as high as 900 amperes, the sparking is very small. Our engraving, Fig. 2, shows a view of this motor driving the cable drum. A 36-inch belt from the armature pulley to a 24-foot flywheel operates the cable machinery, and up to the present time has displaced the engines to the entire satisfaction of the company.

The rheostat to operate such a heavy motor is a novel affair designed by the chief electrician, Mr. Charles Grover. It consists of twelve multiple coils of No. 9 iron wire, each having three points of commutation. These coils are immersed in a tank of running water. Glass plates at intervals prevent electrolytic action, otherwise the wire would last but a short time. The rheostat is on the negative side of the motor to eliminate the possibility of grounds. The diagram, Fig. 3, shows the connections for controlling the motor and the armature rheostat. The letters refer to the following details: J J, positive switch terminals; G G, automatic circuit breaker terminals; E E, Thomson recording wattmeter terminals; FF, FF, etc., reversing switches; A, A, A, are switches making connection with the rheostat; they are worked in parallel and separately. Each switch gives 50 amperes to the motor until the motor starts to move. B, B; C, C; D, D, are switches which are operated simultaneously and cut out one-quarter, one-half and three-quarters of each of the resistance boxes, respectively. The negative switch, L L, when closed, cuts out all of the resistance. The rubber-covered cables, a, b, c and d, lead from the switchboard to the rheostat.



SECTION OF RESISTANCE BOX

FIG. 3.—SWITCHBOARD WIRING FOR MOTOR DRIVING, 9TH AND WASHINGTON STREET CABLE MACHINERY, KANSAS CITY.

JOHNSON STEEL COMPANY, through its president, Mr. A. J. Moxham, has received an order for 20,000 tons of steel rail for electric railway work in Ireland. The freight rate will be $3 per ton.

ELECTRIC CABS IN LONDON.

A special dispatch from London, of August 23, says: The electric cabs that were introduced a few days ago on the streets of London are in great demand. Only two of them are plying for hire, the others having been privately pre-engaged for $5.50 a day. The company owning the vehicles say that they could let hundreds of them if they possessed them. They hope to add three new ones weekly.

A LONG TROLLEY LINE IN OHIO.

Monaghan and Jonathan Head, of Niles, two members of the new East Liverpool, Fredeickstown & Lisbon Electric Railway Company, have bought options on property leading into the city and began negotiations for a terminal at East Liverpool. The company is to build an electric passenger and freight line 29 miles long from that city, connecting with the Erie and Baltimore & Ohio systems at Lisbon and Niles. The right of way is secured. The line follows the old Beaver canal route from Lisbon to the mouth of the Little Beaver. Grading will begin, it is announced, in six weeks. The new road will be equipped with heavy motors, which will haul a good-sized freight train. The company is capitalized at $500,000. Some stock is held in Cleveland.

ELECTRICITY ON THE HARTFORD THIRD RAIL ROAD.

Experiments on the New York, New Haven & Hartford road are said to have shown that the average passenger train on a steam railroad can be duplicated on an electric line with a saving of $5,000 per train. In addition to this saving on the rolling stock, the increased earnings of the roads thus operated are to be counted. Over a distance of nine miles eight trains a day were run under the steam system, with an average daily sale of 400 tickets at 23 cents each, making a total day's earnings of $92. Under the electric system there are 36 trains a day, with a sale of 4,627 tickets at 10 cents each, making a total of $462, or five times the income from the steam service.

TWO-AXLE ELECTRIC LOCOMOTIVE FOR MIXED SERVICE.

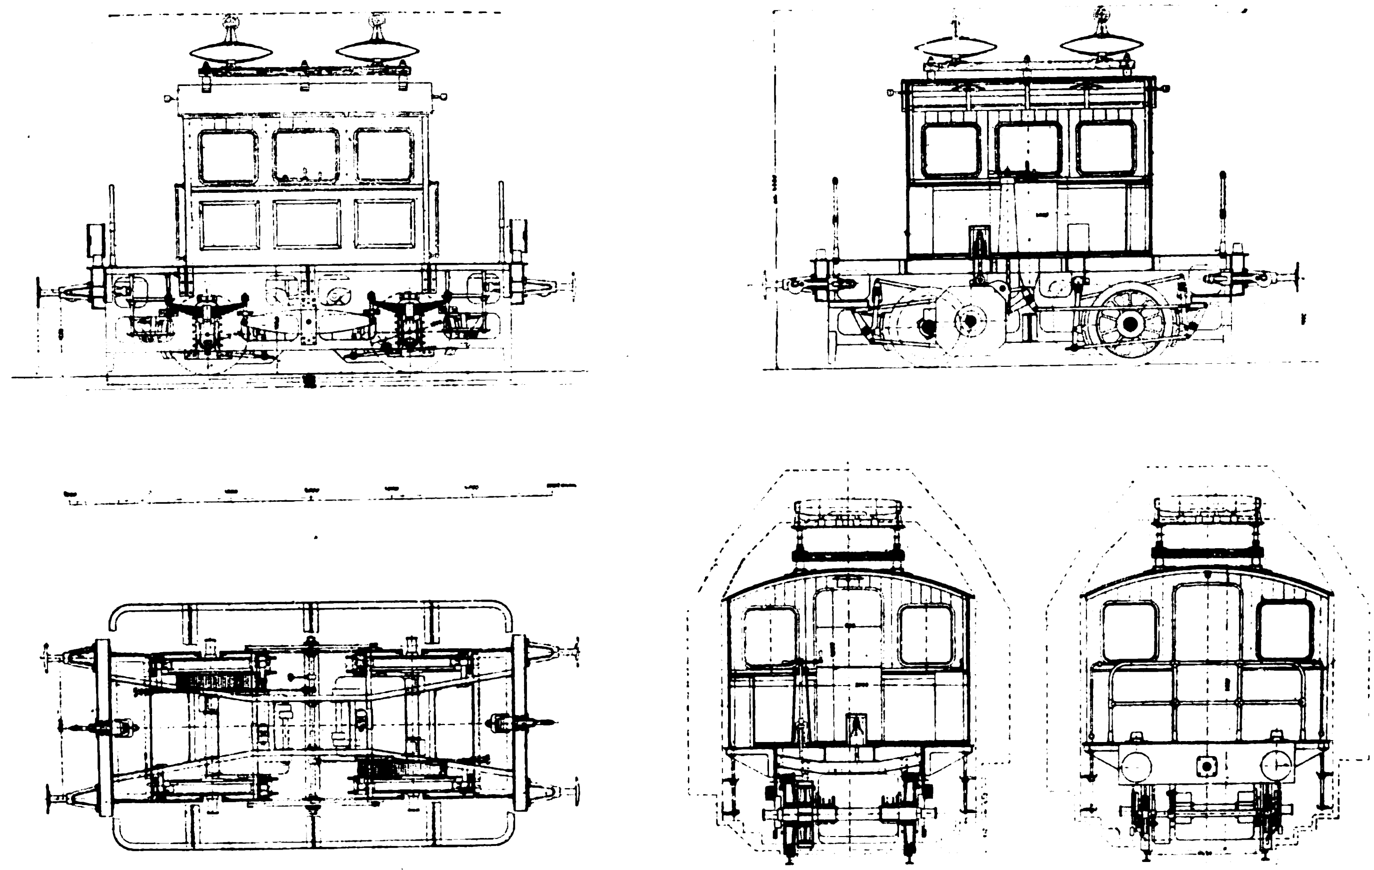
THE locomotive illustrated in the accompanying engravings has been designed by the Allgemeine Elektricitäts-Gesellschaft, of Berlin, for both freight and passenger service, and can also be used for switching. It is designed for 1,432 millimetre gauge, and built perfectly symmetrical. The locomotive has two axles, each driven by a motor, and is designed for the standard Prussian State railway requirements. The locomotive is capable of hauling a train of 120,000 kg. at a speed of 50 km. per hour on a level. For this purpose the traction weight must be about 20,000 kg. In order to accomplish this ballast boxes are provided, filled with sand or other ballast.

The Truck.—The construction of the truck is shown in the accompanying engraving. For the connection of the locomotive with the cars there is a hook with a coupling, and a safety coupling. The drawbar for constructive reasons is not carried out in full, hence every coupling hook must be inserted into the buffer with a special spring. The whole truck is covered with corrugated iron, which adds considerably to its stiffness. The wheelbase is 2,500 millimetres, so that the locomotive can take the shortest curves, and the wheels have a diameter of 1 metre. The weight of the locomotive is transmitted to the journals by means of oval springs, consisting of ribbed steel sheets 90 millimetres wide, and 13 millimetres thick; and an equalizing bar distributes the weight evenly.

The Locomotive Cab.—The cab of the locomotive is entirely enclosed and provided with windows. It is 3 metres wide, so that the motorman can have a full view of the whole train. In order to secure more perfect insulation the upper half of the cab is built of wood. On the walls below the windows are placed the ballast boxes mentioned above and tool lockers. Signaling is effected by means of a whistle, operated by compressed air, furnished by a small hand pump. Should the locomotive be supplied with automatic compressed air brakes, the whistle can be operated from this source.

Electrical Arrangement.—The current is taken off from the overhead conductor by means of two bronze rollers attached to the roof which rollers rest on the springs which press upward vertically against the conductor. This construction was adopted in place of the usual trolley wheel in order to avoid the troubles which would arise with the frequent reversal of direction of the car, and in order also to obviate the necessity of overhead switches. In order to obtain sufficient surface contact between the overhead conductor and the contact device flexible, that is to say, thin wires had to be employed. For this reason the overhead circuit consists of two hard drawn copper wires, 8 millimetres in diameter, placed 150 millimetres apart, but not insulated from each other. The trolley wires are suspended from special suspending wires, so that their lowest point is 4,430 millimetres above the top of the rail.

The locomotive has two motors; one end of each is supported on the axle and the other end suspended by a spring from the truck in such a way that only about one-eighth of the weight of the motor rests upon the axle. The gear wheels transmit the motion to the axle in the ratio of one to three. The pinion keyed to the armature, is of phosphor bronze, and the split gear of the axle is of cast steel. The motors are of the usual enclosed waterproof construction, running at about 840 revolutions per minute, at 500 volts. The regulation is effected by means of a series parallel controller. The normal current at 500 volts is 110 amperes for each motor, each of which has a capacity of 84 h. p., with a maximum capacity of 150 h. p. each. The usual safety appliances to guard against overload, lightning, etc., are provided.



ELECTRICAL ENG'R. N.Y

ELECTRIC LOCOMOTIVE DESIGNED FOR TRUNK LINE TRAFFIC ON GERMAN STATE RAILWAYS, BY THE ALLGEMEINE ELEKTRICITAET GESELLSCHAFT, BERLIN.

THE QUALITY OF TROLLEY OPPOSITION.

The greatest opposition to the construction of the Portsmouth, N. H., and York electric railroad came from a number of citizens at York Harbor, and among the passengers on the first car was the man who contributed the most cash to fight the road. A citizen of Kittery, who advertised his house for sale because the line was built, has been the best customer the road has had so far. A conductor on one of the cars relates a good story about a family who wished that the line would never be built. On Sunday last this same family were taking a pleasure ride over the route, and when the car arrived in front of their residence one of the ladies politely asked the conductor to hold the car while she went into the house to change her hat.

LAMB ELECTRIC CABLEWAY FOR A GERMAN CANAL.

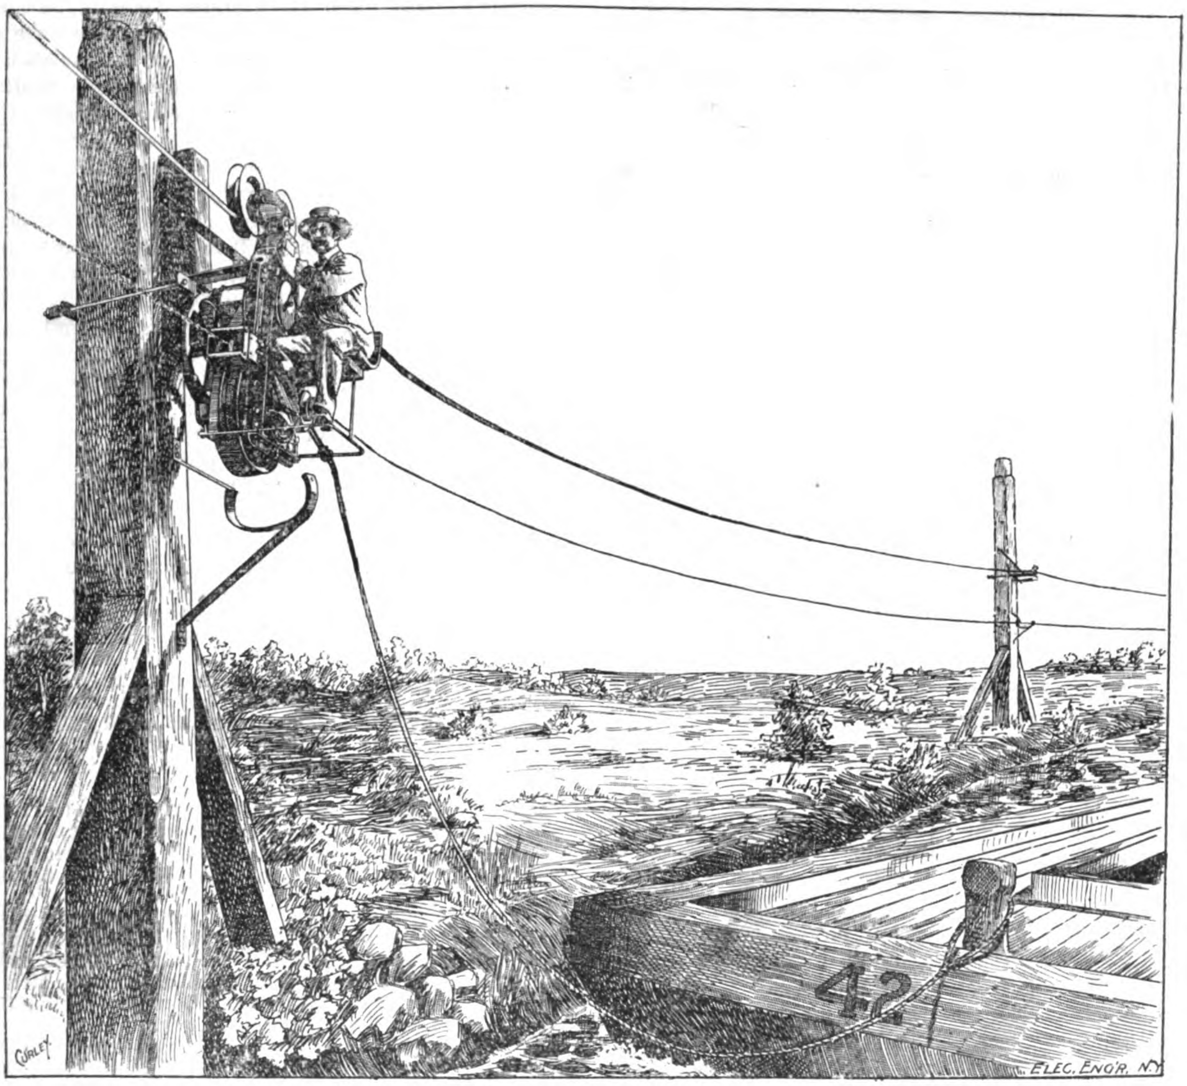
SINCE the trial of towing canal boats by the Lamb electric cableway, Mr. Lamb, in connection with the Trenton Iron Company, has been busy in improving his motor and line details, to meet the special conditions that towing canal boats present.

The test at Tonawanda, N. Y., was in every way a success. Mr. Barnes, the expert for the State, summed up his report by stating: "This electric towing system presents so many meritorious features that I have no hesitation in indorsing it as the system deserving preference over any other hitherto experimented upon, or likely to be devised in the near future."

by two reductions in speed, which has increased the pulling efficiency of the motor at least 50 per cent. In fact, the pulling power of the present motor is remarkable.

The elliptical grooved sheave that engages the traction rope is put about a cylindrical electric motor of the Storey type, the field of the motor acting as the axle for the sheave; thus, there is practically a differential block working a capstan, and the combination of those two powerful mechanical forces is applied directly to the towage of the boats.

A third great advantage obtained in shortening the motor was the lessening of its weight. The Tonawanda motor weighed 3,000 pounds; the new motor weighs 1,300 pounds. A great improvement has also been made in the upper and lower saddles that support the carrying and traction cables; they have been very much simplified.



LAMB ELECTRIC CABLEWAY FOR GERMAN CANAL HAULAGE.

(Drawn from Photographs.)

The order for the Erie Canal trial plant was given only a few weeks before its trial, and no time was available to change from the existing model which was designed especially for the purpose of hauling logs out of swamps. The conditions for this work differ considerably from canal boat towing. In log hauling the length of the motor is comparatively immaterial. At Tonawanda the low bridges under which the motor had to go, necessitated digging ditches in the side of the tow path, through which the bottom of the motor passed, as the motor was 9 feet in length from top to bottom. It was, therefore, important to lessen the height of the motor, as much as possible. How well this has been done is shown in the fact that the new motor, as built for a canal in Germany, is only 5 feet in length, while the Tonawanda motor was 9 feet.

In improving the motor in point of length a still more valuable improvement was made, namely, the worm gear was done away with and the gearing made by direct spur gear

It seems unfortunate that the State improvements in widening and deepening the Erie Canal should have prevented before this date the erection of the Lamb electric cableway by the Cataract General Electric Company, who have the franchise for that purpose. Especially is this so, as it now seems probable that a German canal will have the credit of being the first to substitute the electric cable motor for the mule. The accompany engraving was made from photographs of the German canal motor, the plant for which has been shipped recently by the Trenton Iron Company to that country.

There are hundreds of miles of American canals upon which millions of dollars have been spent for construction, which only wait on the Erie Canal to demonstrate the actual working of the electric cableway, when, as was the case in the introduction of electricity on street railways, new life will be given to the industry, and the country's bulky freights will once more be carried as in Europe by the cheapest of all methods, the canal.

VOL. XXIV NEW YORK, SEPTEMBER 9, 1897. No. 488

CAR TRACKS AND PAVEMENTS.

IT is said that the old Hewitt or center-bearing flat-rail, so generally employed on American street railways up to the advent of the electric car, was designed with the special object of keeping all other vehicular traffic off the car tracks. Whether this be true or not, the fact remains that that form of rail did not accomplish its alleged object, but on the contrary, its construction, while it did not keep other vehicles off the tracks, certainly induced them to stay when once there, on account of the difficulty of turning aside. There is still some of this old track left, but it is fast disappearing, owing to the general outcry against it from all sides, and to the fact that it is unsuitable for electric traction. But the substitution of a different type of rail in many cases has not met with the success hoped for, and the reasons are not difficult to discern. The question of street car tracks presents itself in two aspects, that is, from the side of the railway company and from that of the municipality, whose aim it is to have well paved streets. If a vote of the railways were taken it would perhaps be found that a majority would favor the old center-bearing rail, in girder form, not because it discourages poaching on the company's preserves, but because that type of rail does, as a matter of fact, possess advantages, due to its cleanliness, etc., that make it particularly well adapted for electrical work. But the edict against the rail has gone forth beyond the hope of revocation. Yet, we doubt whether the railway companies or the municipalities have, in the majority of cases been satisfied with the newer types of rails, even where the choice was free. This conclusion is inevitable after reading two papers read before the American Society of Civil Engineers by Messrs. Jas. Owen and Edward P. North, and the excellent discussion had thereon. As pointed out by the authors the question is frequently complicated by the relations existing between the railway company and the municipality. Thus, we may have three conditions, (1) where the municipality owns both track and street, (2) where the railroad company assumes the care of the entire pavement in the street, and (3) where the municipality cares for the pavement outside the tracks, and the company cares for the track and the pavement between the rails. The first two conditions are so rare that they scarcely require extended consideration, but the third case cited is one generally prevailing in the United States. Mr. Owen suggests that it would be of undoubted advantage to have the control of track and pavement vested in one authority, as more economic results can be obtained, and the riding and the driving publics would be placed on a fairly equal basis. But he is bound to admit that the general unsatisfactory administration of municipal affairs at the present time is a great barrier to municipal control, a sentiment in which we agree broadly with him. To place the entire pavement in the hands of the railroad company, however, does not commend itself to Mr. Owen, either, and for obvious reasons, as ideas as to the character of a good pavement might be likely to differ. Coming to the question of the type of pavement best adapted to streets containing street car tracks, it is probably true that the bad results obtained with nearly all kinds of pavements, even with the newer rails, is due to the extreme haste in the construction of the work, lack of appreciation of the future use and requirements of the road, and to lack of funds also. Indeed a prominent street railroad superintendent is credited with the remark that every street railroad track will, on an average, have to be renewed every ten years. This statement is probably not an overestimate, and considering the cost involved to the railway companies, it is evident that the track ought to receive as much consideration at the outset as does the power house. The influence of the rails on the street pavements per se is also a subject of pre-eminent importance, and in the paper of Mr. North, specially devoted to this aspect of the case, he shows the many conflicting conditions which have to be satisfied in order to attain permanency, with a satisfactory roadway for all kinds of traffic. After reading the various descriptions of rail sections and pavement constructions adopted, and the results obtained, one is led to the mournful reflection that this problem has not yet been fully solved by any means. Opinions differ even as to the ideal track arrangement. Thus to Mr. Owen, the ideal road with trolley tracks is probably the extension of Beacon street, Brookline, Mass. Here we note one wide roadway in the center, the trolley tracks sodded with grass, and a driveway on each side for local access. But, alas, it has been found that it is impossible to maintain the track at a good surface owing to the loam working down into the gravel bed beneath. Besides, the life of the ties is shortened, and in winter the freezing of the loam causes an upheaval of the surface so great in places that it has to be trimmed off in order to allow the cars to pass over without scraping, thus defeating the very object of having it a grass reservation. It would thus seem to be a good maxim for railroads to "Keep off the grass." There is also another aspect to track construction in its relation to the municipality, and that is the obstruction which it presents to street cleaning. Referring to this aspect of the case, Col. Waring, Street Cleaning Commissioner of New York, states that a recent calculation shows that if all the streets in New York City of suitable grade were asphalted, and if all the street tracks were like that laid on 106th street (a girder rail with a wide tread), allowing of easy sweeping, the $1,200,000 now paid out annually for street sweeping would be reduced to $700,000. Commenting on this fact, Mr. North goes a step further and shows that the sum of $500,000 which might thus be saved, at an interest of three and one-half per cent., represents a capital of over $1,400,000, a sum more than sufficient to put asphalt on all the streets of Manhattan Island, where the grade would not be too steep. These are figures worth contemplating by all municipalities, as well as by street railway companies. Of course the paramount question with the latter is to secure a clean, solid track, but we believe that much trouble could have been avoided in the past and much may still be avoided by a due consideration of the needs of all the classes of traffic for which the streets are provided. The papers and discussion in the transactions of the American Society of Civil Engineers are a most valued contribution on this subject, and their study will well repay every street railway manager.

THE MATHEMATICIAN AND THE PRACTICIAN.

IT would seem to be almost a work of supererogation to undertake at this late day a defense of those pursuing the science of mathematics of high or low degree; yet that is what Prof. Forsyth practically undertook to do in his presidential address before the Mathematical and Physical Section of the British Association at Toronto. Such a defense is not ill-

timed, considering the criticisms that are still made not only by the "practical" man whose knowledge of mathematics extends no further than the rule of three, or oftener of thumb, but also by engineers and even by physicists. To the criticism that pure mathematics usually leads to results of no immediate or even apparent practical application, Prof. Forsyth very properly replies that the same criticism may be laid at the door of many physicists, much of whose work is of the same character. Yet no one would limit the physicist to researches having only direct and immediate practical application as their final object. Such a course would put a blight upon science and defeat its highest objects. But Prof. Forsyth asserts that the charge of the unpracticalness of the pure mathematicians is not true, and that, on the contrary, in many cases they are guided in their investigations by the possibility of practical issues. He is undoubtedly justified in his contention that they cannot accept practical issues as the sole guide considering that practical issues widen from year to year and cannot be foreseen in the absence of a divining spirit. Whatever complaints may have come from practical workers as to the paucity of results of higher mathematical work, electricians and electrical engineers assuredly have no just cause for complaint. One could mention a dozen practical results of the highest importance traceable to mathematical investigation, and it need hardly be pointed out that modern alternating current work has been raised from the condition of empiricism to a scientific basis by the application of mathematical analysis to the results of experimental research. So far from the mathematician descending to the level of the practical man, Prof. Forsyth is rather of the opinion that the tide is turning and that the so-called practical man is gradually raising himself up toward the plane of the mathematician. He finds confirmation of his view in a glance at modern textbooks of engineering, and he goes so far even as to assert that a properly trained engineer should now possess a mathematical skill and knowledge in some directions, which not very long since could not freely be found among the professional mathematicians themselves. As stated at the outset, mathematicians need no apologists, but it is just as well to give the objectors an occasional sermon as Prof. Forsyth has done.

THE COST OF ARC LIGHTING.

WHILE the cost at which an arc light can be manufactured must always remain more or less a matter of the individual conditions of each plant, it is equally true that the price at which cities and towns can secure that light affords an excellent idea of the possible margin. The figures that find their way into print when some new municipal plant is proposed are often fantastic and grotesque to the last degree, and do infinite harm. A community which has been in the habit of paying $100 per year per light is staggered when confronted with a mass of "data," collected by a junketing committee, going to show that such lights can be made by a city plant for $50 a year, and the local company is at once bulldozed into doing its city business at a loss, or has the exquisite pleasure of seeing the city start a rival plant.

Figures recently compiled, not from two or three plants, but from nearly 1,100 plants, with 300,000 lights, scattered over forty-six States, and including stations of all sizes under all conditions, ought to be trustworthy. These figures show that the general average contract price for lights burning 3,326 hours a year, with coal costing $3.03 per ton, is $101.18. The cost per lamp hour is .034, and the candle-power per hour for 1 cent is 580. In Pennsylvania, with coal at $1.56 per ton, the prices average $85.75, and in Ohio, with coal at the same price, the prices average $78.87. But in Pennsylvania the average burning is 3,931 hours per year, whereas in Ohio it is only 3,350. In California, with coal up to $7 per ton, the average price per light is $119.68; while in Colorado, with coal at only $3.18, the lamp price reaches $129.31, but the Coloradan gets 100 c. p. more for 1 cent than does his Californian brother, owing to the fact that his lamps burn more than 500 hours longer each year. It is peculiarities and idiosyncracies like these, due to local conditions of cost of labor and fuel, cost of land and buildings, size of the community, number of lights, and other things, that render so absurd and unfair the tables offered to a credulous public by such municipal lighting experts as Prof. Parsons, Prof. Bemis, Mr. E. M. Grout and others.

THE FAILURE OF THE PHILADELPHIA MUNICIPAL GAS PLANT.

IT will be remembered that a short while ago we published some figures from the report of a special committee of investigation showing the frightful loss incurred in the operation of the municipal gas works of Philadelphia. The lost to the city was estimated at $700,000 a year, and the cost of labor was three times the average of that in private plants, on the basis of relative output. Evidently something had to be done, and Mayor Warwick now proposes to the City Council that the plant be leased; so that its immediate and necessary repair, improvement and enlargement may be provided for. He says: "This work will require the expenditure, within three years of at least $5,000,000, which the city cannot obtain except by increasing the tax rate. The subsequent enlargement of the plant to keep pace with the city's growth will require at least $10,000,000 more during the term of the lease, for which also the city has no resource except taxation. I have most carefully considered the matter, which is one of great importance to the city, and I submit it to you, deeming it worthy of your most earnest consideration."

The United Gas Improvement Company offers to take over this miserably mismanaged plant on a lease, it is understood, spending $10,000,000 to bring it up to date, paying the city $1,000,000 in cash, and turning in a rental that in thirty years will amount to not less than $36,725,000. It is impossible not to believe that the offer will be accepted, and it is a mounrful commentary upon the municipal plant craze that at a time when private gas works in other large cities are all exhibiting an appreciated value, this Philadelphia plant is a wreck, and will owe its rescue to private enterprise and good management. Yet, we do not regard the Philadelphia instance as exceptional. There may be and probably are several municipal plants well run, but it is as sure as the rising of the sun that the great majority of them are carried on at an actual loss.

GLICKMAN'S WHISKERS.

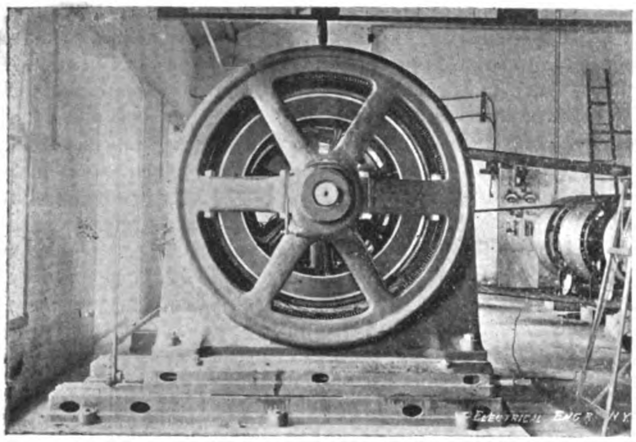
MR. ISAAC GLICKMAN, of Bayonne, N. J., carrying three mackerel and some highly ornamental whiskers on one of the trolley cars of the Consolidated Traction Company was set upon by five toughs, who slapped his face with the fish and when they retired from the scene of conflict carried with them large handfuls of hair as mementoes of the incident. Although the conductor and motorman came to his rescue, Glickman sued the company for the loss of his whiskers, and the court has now held that the company was not responsible. The value of the whiskers was put as low as $200, which is moderate enough, but we must confess that our sympathies and opinions are with the corporation. If anybody was to blame, it was the police force of the vicinity. Obviously, it would not do to charge damages upon the owner of a hack or of a hired bicycle, because the person riding happened to excite the pugilistic or thievish nature of some blackguard or other, and the trolleys have trouble enough of their own without being responsible for the derelictions of the police.

MODERN TELEPHONY.

ONE of the earliest fields for the development of practical telephony was southern New England, and it may truly be said that the priority thus established has been well maintained by the energy and progressiveness of the company which has been working in that field. We illustrate and describe in this issue one of its latest exchanges just finished, that at Hartford, Conn., and it will be noted that the study to give good service at moderate rates and to open up new channels of usefulness for the telephone has gone far toward developing a system that might be regarded as a perfect demonstration of practical modern telephony in America. The Hartford exchange is neither very large nor very small, but hits the average in size and affords an excellent criterion. The map accompanying this article gives a striking idea of the manner in which a Hartford subscriber can easily reach every corner of the State of Connecticut over the multitudinous circuits of the ubiquitous Southern N. E. Company.

NIAGARA POWER DISTRIBUTION BY TESLA MOTOR.

Manager Frank G. Lott, of the Buffalo and Niagara Falls Electric Light and Power Company, is remodelling his station at Niagara Falls, and among other improvements has had the Westinghouse Electric and Manufacturing Company install a 400 horse-power motor of the Tesla induction type.



TESLA 2-PHASE MOTOR, GORGE RAILWAY, NIAGARA FALLS.

This motor is the largest of the kind ever made, and it is to have a companion of the same size and class. The new motor takes the current direct from the generators in the power house of the Niagara Falls Power Company at 2,000 volts. The two 300 horse-power motors formerly in use in this station have been thrown out and these later and larger motors installed. The economy of the new motor will be generally recognized, and the picture well portrays the size of the machine.

COST OF STEAM POWER.[1]

BY H. A. FOSTER.

THIS paper is submitted to the Institute with the hope that it may be of some assistance to other members who may be called upon for opinions as to cost of power, and as a record of a rather persistent attempt to learn something about the subject a little more diverse in conditions than the writer has been able to find in a somewhat extended search.

[1]Read before the American Institute Electrical Engineers. Abstract.

The author states that all the results are based on indicated, and not on net power, as is most usual, and the reasons are given. He gives a list of various types of plants on which test was made, and attention is called to the fact that while it is acknowledged that not enough were tested of any kind to enable one to compute a fair average, yet the argument the writer wishes most strongly to emphasize is, that, even in the kinds of business running most nearly alike, and having large plants of almost identical design, the cost of power varies so much that it is unsafe to state an average cost for any, but, given all the conditions, it may be possible to state approximately what the cost will be for the particular plant under consideration.

In Table I. the rated horse-power of engines is in most cases the maker's rating. In Table II. it will be noticed that ten plants have no charge for water, it being obtained from adjacent streams. One item that amounts to a considerable expense in cities is the removal of ashes; in some cities the authorities remove ashes and use them for filling, the mills being at no expense except to wheel them outside the boiler room. Table III. gives the types of engine employed in the various plants tested. The author has added additional tables showing costs for the year, day and hour per horse-power and the rated capacity of plant, the percentage used, and compares the operating and fixed expenses per hour and by percentage each is of the total.

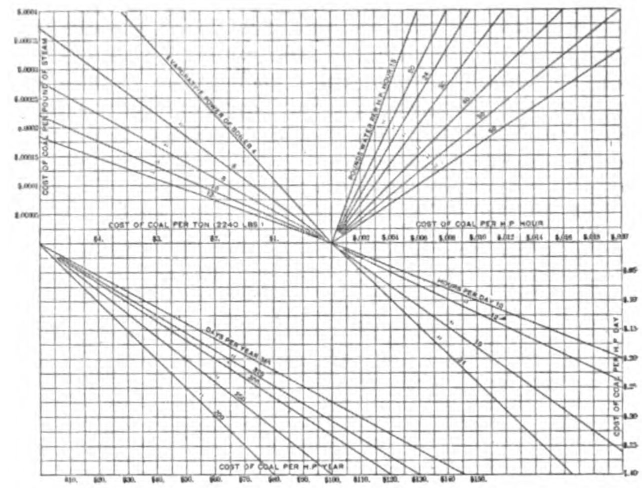


CHART FOR DETERMINING COST OF COAL PER HORSE-POWER PER ANNUM.

From this diagram the cost of coal per H. P. per annum is calculated as follows:
Beginning at "Cost of Coal per Ton" at left of centre of sheet, ascend vertical line to diagonal marked "Evaporative Power of Boilers," then follow horizontal line to the right to diagonal marked "Pounds Water per H. P. Hour," then follow vertical line downward to diagonal marked "Hours per Day" and from this point follow horizontal line to the left to point of intersection with diagonal marked "Days per Year." From this point of intersection follow vertical line downward to a scale at bottom of the diagram giving "Cost of Coal per H. P. Year."

Attention is called to the fact that in one case a portion of the charge for replacing a whole bank of boilers is included, the original installation having lasted about three years. Several of these "extraordinary" items were found, and must necessarily be included under power costs.

Attention is also called to another of those items often overlooked in estimates of this kind, namely, the use of different

TABLE IV.

seem to agree quite as closely as could have been expected, yet the writer wishes to still further emphasize the fact that the extremes in all cases are too far apart to make it correct to state average cost in general. (See Table IV.)

Through the kindness of Mr. L. B. Stillwell, electrical director of the Cataract Construction Company, the author has included in this paper a very useful diagram developed by him for deducing the cost of coal per horse-power for any given case. This diagram is shown on page 233.

A SUMMARY OF ROENTGEN RAY THEORIES.—I.

BY A. VOSMAER AND F. L. ORTT.

(Electrical Research Laboratory, The Hague, Holland.)

THE most important question whether Röntgen rays are to be considered as falling into the domain of light, or whether they are something else, has occupied so many minds, that the literature on this subject has grown enormously; but is it settled yet whether they are transversal waves of very small wave-length, or longitudinal waves, or vortex motion of the ether, or longitudinal impulses, or due to electromagnetic dispersion, or radiant matter? Having read so many theories, with so many supporters and opposers, one gets puzzled what to believe. Not a small part of the confusion is caused by the number of contradictory experiments; and no wonder at this, the question being, in fact, of the utmost complication—that is to say, not only as to the nature of the rays themselves, but also the way in which to get them. Being engaged in the study of silent electric discharges, it was rather in our line to consider the question of cathodic, as well as of our anodic, discharges. Thus we arrived at a conclusion about the nature of Röntgen rays, which explains a great deal, though we must confess that certain assumptions have to be made. This is not an attempt to explain this most difficult problem, but to suggest an hypothesis that is most nearly in accordance with experiments, so far as they go.

We consider Röntgen rays to be nothing but discharged cathode rays, and will now test this hypothesis by seeing how it will explain some of the most striking experiments and facts. As a matter of fact, cathode rays are deflected by a magnet; they obey the law of attraction of a current by a magnet; i. e., they behave as a current or stream of negatively charged particles. These negative particles impinge upon the glass wall of the tube, which, as is well known, possesses a strong positive (external) charge. Is there anything strange in the idea that those particles may lose their charge when in contact with the positive charged wall, and proceed on their way as discharged particles? These discharged particles cannot be, and are not, attracted by a magnet; why should they be? Hence the essential difference between cathode and Röntgen rays is explained. Röntgen rays would thus discharge a negatively or positively charged body, as a matter of course, since any electrified body, struck by neutral particles, always loses its charge.

Now let us consider some important details; in the first place, with regard to the focus tube. Some people do not accept the property of being reflected as possessed by the Röntgen rays. It seems to us that the experiments of Tesla with his T-tube, allowing him to take simultaneously a sciagraph from reflected and from rays that have passed through different plates of metal, are conclusive in this respect; but they prove that the total amount of reflection varies not very much for the least and for the best reflectors; the maximum result obtained with zinc (platinum does not seem to have been tested) was only 3 per cent. Probably platinum will give a higher percentage of reflected rays; but even then it does not sufficiently account for the large difference of efficiency of the ordinary and the focus tube. According to our theory the real cause of the high efficiency of the focus tube lies in the fact that the cathode rays strike on an actual anode, instead of upon an anode by induction.

This, so far, is not new. To quote Lodge, in an article written some time ago: "Hence, undoubtedly the X-rays do not start from cathode, or from anything attached to it, but do start from a surface upon which the cathode rays strike, whether it be an actual anode or only an anti-cathodic surface; best, however, if it be an actual anode."

Röntgen and Rowland had discovered the same thing. According to our theory, it is evident that the negatively charged particles can lose their charge sooner and more completely when they strike an actual anode, than when they strike an anode by induction (of greater surface, and thus of smaller density). Everybody will agree with Prof. Peckham, where he says that the discharge-tube is a resonator for its coil, and when the coil and tube are properly attuned the maximum effect is obtained. We should say, when the discharging capacity of the surface struck by the cathode rays can keep time with the vibrations of the intermittent current or stream of charged particles, the most intense Röntgen rays will be obtained. If discharging—or, better to say, neutralizing—of the waves of negative particles from the cathode be not synchronous with their impinging upon the focus or wall, they cannot lose all their charge, and will proceed either as particles with a minute negative charge, or with a minute positive charge, or perhaps mixed with neutral parts. The result will be feebler Röntgen rays, and, according to the preponderance of the one or the other particles, these rays will discharge an electrified body and give it charge according to its own charge. Borgmann found that a negatively charged plate, when exposed to Röntgen rays, lost its charge to become positively charged; when the plate was positively charged, it lost part of its charge. Righi found just the contrary; a positively charged plate lost its charge to end with a negative charge. Porter, and nearly all other experimenters, found in all cases a complete loss.

We could explain these differences by admitting that neither Borgmann nor Righi had pure Röntgen rays, but had them mixed with positive and negative rays, respectively. We consider Porter's $X_1X_2X_3$ rays and Lenard's gamut of rays of more and less magnetic deflectibility, as Röntgen rays of less and more purity, i. e., neutrality. The more perfectly the negative charge has been taken away by the anode—without, however, imparting a positive charge instead—the more intense the Röntgen rays will be, and the stronger penetrating power they will possess. It is hardly necessary to say that it must be very difficult to obtain perfectly neutral rays; this end will obviously only be attained when the whole system of generating—current, frequency, self-induction, capacity, vacuum, size and form of tube, and all the rest—be in true harmony with one another; and to realize this, means no small thing to do in practice.

We do not venture to say that our theory explains everything, but we do think it explains much; we do not ignore the fact that it is difficult to understand how the Crookes' radiant matter could pass through the glass wall as discharged matter, but the theory of ether motion also presents difficulties. Experiments on the Lenard rays passing as charged particles through aluminum, are described in "Nature," of May 27 (p. 93). Why should the etheric disturbance in the air answer so closely to the vacuum in the tube? Why should the rays, if they be ether vibrations, which in any case must be of so short a wave-length that the well known properties of light do not show, make any difference whether they are obliged to pass through one or the other metal or material? If the intermolecular space be of any influence on them, one should expect refraction in those materials that show greater resistance to the rays passing.

The strongest proof for our theory is Lafay's experiment, where he found that Röntgen rays, passed through a negatively charged leaf of silver, can again be deflected by a magnet, and in the same direction as the cathode rays in the tube; and when the leaf was positively charged, in the opposite direction. That means that neutral, non-deflectible rays, after recharging, become again sensitive to the magnet; the deflection being absolutely in accordance with electromagnetic laws of attraction and repulsion. Unfortunately this experiment, repeated by Lodge, has not been confirmed by him; but it is easy to understand that recharging, just like discharging, is no simple thing to accomplish.

(Our next issue will contain a review of the theory of Messrs. Vosmaer and Ortt.—Eds. E. E.)

VARIETIES OF CATHODE RAYS.

Prof. Silvanus P. Thompson described last week to Section "A" of the British Association his researches on the varieties of cathode rays which have been discovered inside a vacuum tube excited by electrical discharge. He classifies these rays as follows:

(1) Orthocathodic rays, which are the orthodox rays that are deflectable by a magnet, that are fluorescifiant and which excite Röntgen rays.

(2) Paracathodic rays, which are also deflectable and fluorescifiant, but which do not excite Röntgen rays.

[1]From London Nature.

(3) Diacathodic rays, which although fluorescifiant are non-deflectable by a magnet and do not excite Röntgen rays; and

(4) Isocathodic rays which differ from the diacathodic rays in being deflectable by a magnet. The third class of rays is produced beyond an electrified metallic screen or gauze plate placed in the path of ordinary cathode rays. They produce a species of fluorescence of a yellowish or greenish color upon the inner surface of the tube, and will cast shadows of intervening objects.

MISCELLANEOUS

A NEW METHOD OF MEASURING HYSTERESIS IN IRON.[1]

BY J. L. W. GILL, B. A. Sc., of McGILL UNIVERSITY, MONTREAL.

WHEN a specimen of iron is passed to and fro through a magnetic field without any motion of rotation, the direction of the field being reversed each time the specimen passes out of the field, the iron passes through a complete magnetic cycle for each cycle of motion, and a definite amount of energy is lost, due to hysteresis in the iron. Since energy is supplied only in the form of mechanical work upon the specimen, the hysteresis loss is, by the law of the conservation of energy, numerically equal to the resultant mechanical work expended.

The instrument described below is based upon the above principle, and its function is to measure the work so expended.

The magnetic field is obtained by the use of a solenoid wound on a brass tube. The specimen to be tested is placed in a stirrup, which is sufficiently small to pass through the solenoid, and is suspended by a helical spring, the point of suspension being vertically above the center of the solenoid. Another helical spring extends from the bottom of the stirrup to a point vertically below. This serves to keep the stirrup steady. The stirrup is suspended so that when the solenoid is in its lowest position the specimen is out of the magnetic field, being above the solenoid. As the solenoid is moved up the stirrup and specimen pass through it, and when the solenoid is in its highest position the specimen is practically out of the field. If the solenoid be moved once up and down, the field being reversed when the specimen is out of it, the specimen passes through a complete magnetic cycle, provided the specimen has been once through the field and is initially in that particular cyclic state.

The resultant work done on the specimen may be determined by observing the attracting force when the solenoid is in different positions, and then drawing a distance-force curve. The integral of this curve gives the resultant work done on the specimen. The force at different points can be determined by calibrating the springs which support the stirrup, and then observing the extension of these springs. The author has determined the hysteresis loss in different specimens at different inductions by this method, the extension of the springs being observed with the aid of a microscope.

To make this method practical, a simple integrating apparatus is attached to the instrument above described, by which the work done is integrated automatically. The constant of the instrument is determined by placing a known weight in the stirrup, and observing the amount of rotation communicated to the disc when the solenoid is moved through a known distance. The specimen may be taken through a number of cycles and the readings allowed to accumulate. The average of a number of cycles is thus obtained.

ON THE RELATIONS BETWEEN ARC CURVES AND CRATER RATIOS WITH CORED POSITIVE CARBONS.[1]

BY HERTHA AYRTON.

WHEN an arc is burning between a solid negative carbon and a positive of given diameter, the P.D. between the carbons varies according as the positive carbon is cored or solid.

When the Length of the Arc is Kept Constant.—1. The P.D. is in all cases higher with the solid than with the cored carbon.

2. With a solid carbon the P.D. continually diminishes as the current increases; with a cored carbon the P.D. either diminishes much less than with a solid carbon, or remains constant for all currents above a given value, or actually increases with the current after falling to a minimum.

With a Constant Current.—1. The P.D. is always higher with solid carbons than with a cored positive carbon, but the difference between the two diminishes as the arc increases in length. 2. The rate of change of P.D. with change of length is constant with solid carbons, but diminishes as the length of the arc increases with a cored positive carbon. 3. This rate of change becomes smaller and more nearly constant for all lengths of arc as the value of the constant current increases. 4. The P.D. corresponding with length of arc 0 diminishes as the current increases with solid carbons, but increases with the current with a cored positive carbon.

These differences can all be accounted for on the hypothesis that with a given solid negative carbon and a positive of a given diameter the P.D. required to send a given current through a fixed length of arc depends principally, if not entirely, on the nature of the surface of the crater being greater or less according as the carbon of which this surface is composed is harder or softer.

By the term area of the crater is meant the area of the mouth of the crater, or, still more accurately, the plane area of that region of the end of the positive carbon which is sharply cut off from the rest by its peculiar brilliance and whiteness. The area of the soft carbon in the surface of the crater is taken to be the projection on the mouth of the crater of that area of the crater that is composed of soft carbon, and the proportion of soft carbon in the surface of the crater is measured by the ratio of the area of the soft carbon to the total area of the crater. This ratio for each current and length of arc will be called its "soft crater ratio."

The ratio of the area of the hard carbon in the surface of the crater to the area of the crater will be called the "hard crater ratio."

Arcs of Constant Length.—The area of the crater is known to increase as the current increases. With a constant length of arc, therefore, when the current is very small the whole of the crater will be in the core, as the current increases some hard carbon will be embraced by the crater, and the P.D. will therefore, by the hypothesis, be higher than if the whole crater were of soft carbon. The larger the current the greater will be the area of the crater, and consequently the greater will be the amount of hard carbon in its surface; hence, by the hypothesis, the difference between the actual P.D. and what the P.D. would be if the whole carbon were as soft as the core must increase as the current increases, until in some cases the P.D. with the cored carbon, after reaching a minimum, would actually rise as the current increased, as it is found experimentally to do.

Constant Currents.—It has not hitherto been known how the area of the crater varied with the length of the arc. From the hypothesis and the curves connecting P.D. and length of arc for constant currents it was deduced that—

1. When a cored positive carbon is used and a constant current is flowing the area of the crater must increase as the length of the arc increases.

2. The change that takes place in the ratio of the soft carbon to the total amount of carbon in the surface of the crater with a given change of length must diminish as the arc increases in length.

3. The change that takes place in the ratio of the soft carbon to the total amount of carbon in the surface of the crater with a given change of length must be smaller, and the rate of change must become more nearly constant for all lengths of arc as the value of the constant current increases.

Remembering that the ratio of the area of soft carbon to the area of the crater is called the "soft crater ratio," these three conditions may be put thus—

1. With a cored positive carbon, and with a constant current flowing, the area of the crater must increase, and consequently the soft crater ratio must diminish as the length of the arc increases.

2. The change of soft crater ratio with change of length must diminish as the length of the arc increases.

3. The change of soft crater ratio with change of length must be the smaller, and the rate of change must become the more nearly constant the larger the current. The results of tests proved the truth of the hypothesis.

[1]Abstract of a paper read before the British Association at Toronto.

THE "CANADIAN MANUFACTURER," of Toronto, has done a public service by bringing out in its August 6 issue the 1897 Canadian Tariff, the 1897 United States Tariff, the British Tariff, the British Merchandise Marks act and the Newfoundland Tariff. It is a very valuable issue.

HOUSTON, TEX., is considering and discussing a plan to spend $100,000, raised by bonds, for a city electric light plant.

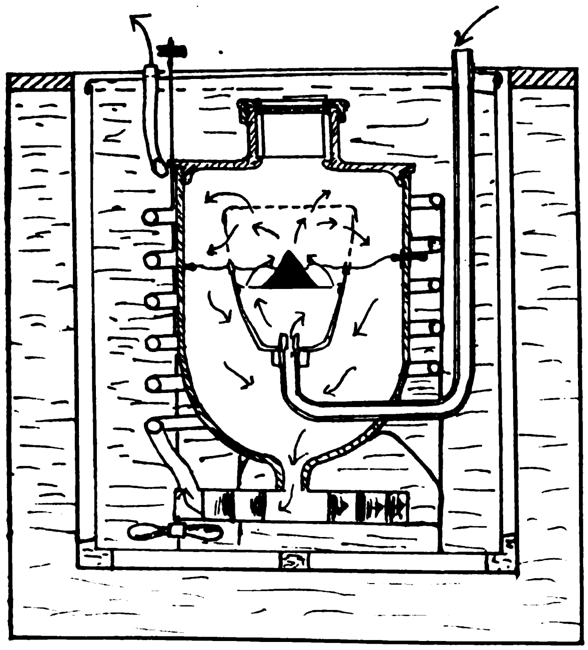
A NEW FORM OF COAL CALORIMETER.[1]

BY CHARLES L. NORTON.

THE utility of an apparatus which would enable an engineer or one not especially skilled in the manipulation of delicate physical apparatus to determine within a limit of about one-half of one per cent. the calorific power of a fuel, is apparent. That such an apparatus has been up to the present time available, is open to question.

The calorimeter which I have designed and which has been developed and carefully studied by Messrs. H. W. Allen and W. E. Parsons, students in the Rogers Laboratory of Physics as their thesis, is of the class of which the Favre and Silberman calorimeter may be called the type. I have borrowed some details from the older forms of this apparatus. The apparatus is constructed as follows: An outer water jacket of nickel-plated brass serves to protect the calorimeter proper from irregular radiation losses. The calorimeter, of thin nickel-plated brass, is cylindrical in form, being about 12 cm. in diameter and 15 cm. high. It has a loosely fitting cover with holes for the inlet and outlet oxygen tubes and ignition wire. The calorimeter is separated from the jacket by an air space, its position being maintained by cork spacing pieces. A rotary stirrer, driven by hand or by a small motor, is placed as near the side of the calorimeter as possible. When filled, the calorimeter holds about 1,000 grams of water.

The combustion chamber is supported on three legs in the center of the calorimeter, and consists of a cylinder with its axis vertical. Its diameter is 5 cm. and its height is 7 cm. The top is a tight-screw cover, having at its center a glass window protected by mica from the heat below. The bottom is a hemispherical shell and is brazed on. It is penetrated



NORTON COMBUSTION CALORIMETER.

by the inlet and outlet oxygen tubes, each about 5 m.m. in diameter. The products of combustion on leaving the combustion chamber pass into a flat box with a spiral partition, and then into a helical coil of tube about three metres in length, and finally escape at the top into the air. The outer end of the tube for supplying oxygen is above the cover of the calorimeter, from which point it passes downward through the water, penetrates the lower part of the combustion chamber wall, turns upward and ends at the center of the chamber. All parts of the combustion chamber and tubing are of copper nickel-plated. The walls of the chamber itself are about one millimetre thick, and are gold plated on the inside.

It is to the receptacle for fuel, or burner as we will call it, that particular attention is called, as the successful working of the apparatus is largely due to this contrivance. A platinum crucible, with a hole in the center of the bottom, is slipped over the end of the supply tube in the center of the combustion chamber. At about half its height the crucible is divided horizontally by a disk of sheet platinum. This disk has a great number of fine holes near its edge, but it is not perforated near the center. Upon the center of this plate the sample of coal to be burned is placed. The disk fits into the crucible loosely and may be taken out for cleaning, a series of indentations made in the outside of the crucible serving to keep it in position. A tight cover, perforated with many fine holes, is made of platinum somewhat thinner than the crucible walls. The upper parts of the crucible walls are perforated with fine holes. A fine platinum wire, heated by a current, serves as a fuse. It is insulated from the crucible by mica washers, and ends in stout insulated terminals in the walls of the combustion chamber

The manipulation of the apparatus is as follows: The weights of the coal, calorimeter and contents should be taken. The coal is put upon the perforated plate, the fuse put in place, the crucible cover put on, the crucible slipped over the end of the supply tube, the fuse connected to its terminals, the cover of the combustion chamber screwed on, the chamber put in position in the calorimeter, water poured in to immerse the chamber, and the whole put into the water jacket. The fuse is then ignited and the oxygen turned on. The thermometer readings complete the observations. Stirring should be maintained rigorously throughout the entire temperature change.

The oxygen should be saturated with water at a temperature about that of the initial temperature of the calorimeter. To burn one gram of coal requires two or three minutes, and necessitates the use of not more than one-half of a cubic foot of oxygen. It may be shown that the maximum error due to the rise or fall in temperature of the gas and to evaporation or condensation of moisture, cannot exceed one-third of one per cent.

The lightness and good conducting power of the platinum crucible and plate, assure their being at a high temperature during combustion, and to this is due, in my opinion, the completeness of combustion. No trace of carbon monoxide, and no indication of soot is to be found in the resulting gases. The stream of oxygen on entering the crucible strikes the intensely hot plate, and rising through the perforations passes in fine streams close to the pile of powdered coal, an ideal condition for completeness of combustion.

The use of the finely perforated walls and cover of the crucible assure the fuel being kept within the intensely hot receptacle until consumed. In no case has there been any trace of unburned fuel inside or outside of the crucible. To the rigor of the combustion, assured by the construction of the burner, is largely due the speed of the operation. This assures a small cooling correction. A rise of from six to eight degrees has a corresponding cooling correction of about two one-hundredths of a degree.

The results obtained with this calorimeter, when used upon coals of medium softness or upon very hard coals, agree within about one per cent. with the results on the same coals obtained with the Mahler combs. The results agree with one another to within one-half of one per cent. The experience thus far with the apparatus is limited, but leads me to hope that a study of the existing errors may result in an increase in the accuracy of the results to about one-tenth of one per cent.

[1]Abstract of a paper read before the Amer. Assoc. Adv. Sci., at Detroit.

THE PREDETERMINATION OF THE REGULATION OF A TRANSFORMER WITH NON-INDUCTIVE LOAD.

BY FREDERICK BEDELL, R. E. CHANDLER and R. H. SHERWOOD, JR.

To determine the regulation by this method a wattmeter, ammeter and voltmeter are located in the primary circuit. One set of readings is taken with the secondary short-circuited by a stout copper wire, the primary voltage being adjusted until the normal full-load current flows in the transformer or any desired fraction of it. No other data for obtaining a complete regulation curve is required, except the one set of readings above mentioned and the magnetizing current. If a wattmeter reading is taken when the magnetizing current is measured, the data is sufficient to plot a complete efficiency curve, as well as curve for the regulation of the transformer. The two sets of measurements then consist of the reading of a wattmeter, voltmeter and ammeter, first on short-circuit with normal current, and, second, on open-circuit at normal voltage. The wattmeter reading in the first case gives the copper losses; in the second case, the core losses.

It is commonly convenient to use the high-potential coil as primary in the short circuit measurements and the low potential coil as primary in the open circuit measurements. A high potential supply is not then needed, and as no power is required except to supply the

[1]Abstract of paper presented at the Detroit meeting of the A. A. A. S.

losses, the complete test of a transformer may be made with an incandescent lighting circuit for the source of supply, a 50-light transformer being tested from one 16 c. p. lamp socket. The total drop is found by laying off in the proper manner the inductive drop, the magnetic leakage drop and the drop due to ohmic resistance.

The method is theoretically an almost exact one. Practically, it is an exact method and less likely to error than the ordinary method of determining the regulation of a transformer by loading it. The results given in this paper from a long series of tests on seven transformers of various makes, show the reliability of the method, the secondary voltage at full load determined by it, varying usually less than one or two-tenths of a volt from the voltage as found by measurement on the transformer when actually loaded. An approximate method (given by Kapp) used by one of our large electrical companies gives less accurate results.

MECHANICAL

UTILIZATION OF EXHAUST STEAM.[1]

BY GEORGE L. THAYER.

IN four-fifths of the electric light stations we are wasting a by-product of greater relative value than is the case with any other industrial concern. The exhaust steam carries away 85 per cent. of the heat supplied by the boilers. The problem confronting the station manager of the day is this, Can this stream of energy now being wasted be put to some use, and, if so, will it pay to do it? This question can hardly be answered off-hand, but I wish to say that, generally speaking, there is no extension of your business that will pay larger profits on the investment than that of steam heating.

The author then gave brief descriptions of the gravity and vacuum systems of steam distribution, and mentioning the American District Steam Company, of Lockport, N. Y., as the pioneers in central station heating work.

It may seem strange but it is an actual fact that a gravity plant can be changed into a vacuum system and the coal consumption reduced considerably and that, too, with better results in heating. When the boiler feed-water is of a bad quality it will pay to return the water of condensation. Where a good grade of cylinder oil is used there will be no difficulty with the very small amount of oil coming from the heating system. There will be enough fresh feed-water added to prevent any trouble which would come from using distilled water in the boilers. It is needless to say that corrosion and scaling, with their attendant expense, will be largely reduced. However, the loss through wasting the condensed water is not as great as may seem at first. The condensation can be led into an indirect radiator and used to heat the fresh air from outside. The water leaving the coil will have all available heat removed. If, on the other hand, the condensation at 212 degs. be returned to the boiler the radiation loss in the returns may be more than the heat wasted when the water is discharged from the system.

The correct design and construction of the underground mains is a vital point if the system is to be made a success. It is necessary to secure three results. The radiation losses must be small; unless the distance run is excessive they should fall within 5 per cent. of the total system supplied. Expansion and contraction should be provided for. Assuming a range in temperature from 50 to 212 degs., 100 feet of main will expand 1⅜ inches. In a long line of pipe this becomes a serious matter. The mains should be protected from surface water as the pipes are soon corroded through when the pipe covering becomes damp. One standard method of construction is as follows:

At the bottom of the trench is laid a tile drain. Pine logs are bored and the outside surface painted with asphaltum. These are tenoned together and the iron pipe having received its covering is placed inside. Expansion is provided for by a special fitting having a flexible diaphragm doing away with a stuffing box. Service connections are made every 50 feet. The work is simplified by there being no return pipe.

Another method which seems to be successful is to build a box of tarred boards. The pipes are supported a few inches above the bottom of the box to protect them from water which may accumulate at the bottom.

The box is filled with asbestos wool or each pipe is covered with common pipe covering. Expansion is provided for either by expansion joints placed in manholes or, where the pipe is small, by U-shaped offset loops. Whatever method is followed it pays in the long run to have the work well done.

I am indebted to Prof. R. C. Carpenter, of Cornell University, for the following data on condensation in steam pipes: The various university buildings are heated from one boiler plant through underground mains. The pipes are laid in a solid log bored 2 inches larger than the pipe. The thickness of the wood remaining is 4 inches. The logs were painted on the outside with coal tar and sawdust. There is in the system 150 feet 10-inch pipe and 2,050 feet of 6-inch pipe, having a total heating surface of 5,605 square feet. The temperature difference was 235 degs. Twenty-seven h. p. of return steam was required to supply condensation, i. e., 1 h. p. loss for each 820 feet of 6-inch pipe, or its equivalent surface, 1 h. p. being taken as 30 pounds steam at 70 pounds pressure with feed-water at 100 degs. In a more technical form the heat loss .614 B. T. U. per square feet for each degree difference in temperature. With what is considered good practice at the present time the radiator losses can be reduced to 40 per cent. of these figures.

There is no hard and fast rule for the proportioning of radiating surface. Of two buildings of the same construction apparently, one will be warm and the other cold. The formulæ given in text-books are quite complex and involve considerable labor. The method used by a firm in the West which gave good results with a minimum of work, is as follows: The glass surface was figured, first taking total opening of window frame to allow for leakage. The exposed walls were figured and reduced to equivalent window surface. For unfurred brick or stone walls 15 ins. thick 4 square feet was taken as the equivalent of 1 square foot of glass. For ordinary wooden dwellings and furred brick walls the ratio was 1 to 6. Extra warm construction was 1 to 8. For northern Illinois the required heating surface was 1 square foot for 2 square feet of glass. Rooms exposed to northwest winds the radiator surface was increased 10 to 15 per cent. Any unusual conditions were allowed for as experience suggested. Radiator was proportioned to maintain 70 degs. inside with 0 deg. weather outside.

The rates and methods of charging for central station heating vary considerably. There is a tendency to charge according to the space to be warmed rather than by square foot of radiation. For a store 20 x 80 x 14 the charge for heating is about $60. The radiating surface required is in the neighborhood of 250 square feet, or 25 cents per square foot heating surface per year. Such a store will use 5 to 7 tons of hard coal in an ordinary winter. At $7.50 per ton it will cost $45 to $50 per year for heating.

You are selling heat practically in competition with hard coal, and the rates you are able to secure will be based on that method of heating. In the territory covered by this association you ought to get from 10 per cent. to 20 per cent. more than the cost with hard coal. You can offer a much better manner of heating but with the disadvantage of the cost of the radiators and piping. The following are some examples of rates:

Plant 1.—Storeroom, 20 x 90-100, $60 to $70; office, 15 x 20, $20 to $25; bank, 20 x 30, $40 to $50.

Plant 2.—Store, 22 x 60, $50; 22 x 75, $62.50.

Plant 3.—$15 per 100 feet per year, or $2 per 1,000 cubic feet in brick stores; $3.50 per 1,000 cubic feet in dwellings.

Plant 4.—$100 to $125 for ten-room house.

Plant 5.—$0.25 per square foot per year.

Plant 6.—$3.50 per 1,000 cubic feet; heating done by live steam on meter.

As yet there is no meter on the market except that of the American District Steam Company, which is used only on their plants.

The cost of operation outside of interest and depreciation charges will naturally vary greatly in different plants. It should be borne in mind that your profit lies in selling exhaust steam rather than live steam. An increase in business beyond a certain point may not pay if fuel is high and the heating rates are low.

One foot of radiating surface will condense ⅓ pound of steam per hour. Assuming that five and one-half months' steady heating will be the equivalent work for one season, coal at $2 per ton of an evaporation power of 7 pounds, the fuel cost will be 19 cents. If the revenue from 1 foot will be 25 cents, it will probably be found that business does not yield any profit. In the stations of towns of less than 15,000 inhabitants, 75 per cent. of the maximum evening load will be carried for five hours during the heating season. Outside

[1] Read before the Northwestern Elec. Assoc. Abstract.

of these hours the load will run about 30 per cent. for the remainder of the lighting hours. The day power load, if any, will hardly exceed the all-night load. The conditions will be that on the first floor 50 per cent. of heating business can be done with exhaust steam for at least fourteen hours per day. The fuel cost of live steam furnished will be 11 cents per square foot. Another 45 per cent. can be supplied with exhaust steam five hours per day at a fuel cost of 15 cents per season. This would indicate that the profitable heating is that which can be taken care of during the greater part of the evening load. Cost of fuel will determine in each case whether new business will pay on a live steam basis.

Some modifications of central station design will follow when steam heating is added. The boiler portion of the plant becomes of much greater importance. Wastes which otherwise would be small assume greater importance when the work done by the boilers is more more than doubled. Every effort should be made to bring them up to the highest efficiency. The installation of auxiliary devices as "Green's Economizer" will sometimes be advisable.

The use of storage batteries in connection with a heating plant assumes a new importance. It can safely be assumed that during the hump of the load more steam will be used by the engines than can be discharged into the heating system. A storage battery can be used to take a portion of the load during the time. Later in the night when the heating must be done in part with live steam it can be charged at a very small expense for fuel. Assuming boiler pressure 100 pounds, and temperature of water from heating system at 180 degs., 1 pound of steam entering the engine becomes .9 pound at exhaust by adiabatic expansion, a loss of 10 per cent. The steam at atmospheric pressure and weight for weight as compared with steam at boiler pressure contains 4 per cent. less heat. There will be available then 86 per cent. of the heat entering the engine. Engine friction and the loss by external condensation remain practically constant. Internal cylinder condensation is slightly less with the added load. Approximately the battery can be charged with 15 per cent. of the fuel required under ordinary conditions. When conditions are suitable there will be a marked gain by their use.

In alternating plants it will be necessary to provide a direct current load during the heavy lighting hours if batteries are put to this use. A power load would probably be quite small after 6 p. m. Long burning arc lamps could be installed very successfully in this connection. In this case a good construction would be made with a 220-volt power current and a three-wire system for the arc lamps. Close regulation not being necessary, considerable complication due to cells and boosters could be avoided.

The generator might in some cases be used as a motor during the heavy lighting load, in the absence of an arc light or power load for the batteries.

To offset these advantages is the high cost of the battery and unwillingness of the smaller stations to make large increase in their investment for the sake of economical operation.

Once a heating system is in operation, it becomes a much easier matter to secure paying power or day lighting load. During the heating season the machinery can be run at a small additional expense, the principal items will be oil and the increased wear and tear. With the coming of the warm months a respectable fan motor business can be worked up, which will tide over the summer months when the station must be run day time for power alone.

LITERATURE

DIE STAATSTELEPHONIE IN WURTTEMBERG.—(Government Telephony in Wurtemburg.) By A. Hassler. Stuttgart; W. Kohlhanner. 1897. 142 pp.; 6 x 9 in. 15 plates: Paper. Price, $1.50.

This is a strictly technical and accurate account of the telephone system as it exists at the present time in Wurtemburg, Germany. The author has omitted no single detail, from the telephone receiver to the switchboard, giving in full descriptions and illustrations of the various apparatus employed, both at the exchange and at the subscriber's end of the line, with the complete diagrams of circuits, switchboards, test board, etc. While we believe that the best American practice is ahead of that shown in the volume before us, there is nevertheless enough interesting matter contained in the present volume to make its perusal by American telephone engineers desirable. The administrative details contained in the work might also contain some useful hints to telephone managers.

LETTERS TO THE EDITOR

ARE TWO SAFETY FACTORS BETTER THAN ONE?

THE criticism by Doe Bird in The Engineer of August 5 on Jim Crow's recent article on insulated iron armored conduit is so utterly absurd that it is almost superfluous to reply to it. Doe Bird is evidently not one of the "Babes" out of whose mouths an all-wise Providence has ordained strength, but is apparently another case of a "fool asking questions," etc. There is surely reason in the assumption that the people who make rules for electrical, or any other construction, have at least a superficial knowledge of the character of the work they seek to regulate.

If it is Doe Bird's intention to assume that insulation is not a prime factor in electrical construction, he leaves no room for argument, but he inspires a boundless sympathy for his solitude. In these up-to-date times there would seem to be no good reason why allowance should be made for "habit," "fog" or anything else but fact, and if it is not a fact that two safety factors are more effective than one, it is certainly time that the engineers of the world were so informed. In almost every branch of house construction, materials are so placed as to support and supplement each other, and it is doubtful if an engineer can be found who is willing to risk the operation of a large factory upon a single engine, boiler or dynamo unit. Why then should the service of an electric plant, or the safety of life and property be left dependent upon a single unit of insulation; especially one of a value undeterminable at the time of its installation, and subject to more or less rapid deterioration thereafter? An examination of ordinary rubber-covered conductors which have been in service for a few years, will demonstrate how supremely ridiculous is the assumption that the "wires of commerce" are so insulated as to secure a "reliable and durable service" if installed in plain iron conduit. Those who want, and are willing to accept proof that such assumption is not well founded, can readily obtain it by a few very simple experiments. The proposition that the insulation of a conduit adds nothing to its efficacy as a safeguard against fire, is a difficult one to understand, and is about as logical as the statement that one two inch stream of water would be as effectual in putting out a fire as four half-inch streams. Neither proposition will admit of argument.

There are those possessing that dangerous thing "a little knowledge," who think that conduits should be insulated for conductors carrying currents of high voltage, while plain iron pipe may be safely employed for conductors carrying currents of low voltage. Experiments will effectually demonstrate the error of this assumption by producing a fire from a current of about three amperes at 110 volts, employing a conductor with defective insulation in a plain iron pipe. A like experiment conducted under the same conditions, but with an insulated armored conduit, will produce nothing but the most conclusive evidence that after the insulation on a conductor has broken down and lost its saving power. Doe Bird's argument is as much out of season as the bird under whose name he writes, while the property owner is yet a long way removed from the doubtful pleasure of entertaining the press boys and insurance adjusters with an account of his losses, and how it all happened in spite of high class workmanship, done in strict compliance with the rules and regulations of the fire underwriters. Perhaps Doe Bird is slyly joking after all.

Your correspondent from the West, writing under date of August 12, suggests that Jim Crow does not properly conceive the function of iron pipe or iron armored conduit as viewed from the point of one who has the prevention of fire in mind, and apparently in support of this conclusion, he informs us that "high insulation is not necessarily a protection against fire," also that he has known of lightning discharges breaking through good rubber insulation and air gap.

The gentleman from Cincinnati might truthfully add that lightning discharges have been known to pass through brick walls, feather beds, army mules and countless other things having no special connection with the subject under discus-

sion, but admitting the truth of these freaky movements of untrammeled lightning out for a good time, there seems to be room for a reasonable degree of doubt as to the accuracy of the gentleman's statement that "high insulation is not necessarily a protection against fire" caused by the average currents and voltages used in interior electrical construction, although he is no doubt approximately correct if he has in mind the placing of lightning rods and other superlatively high tension conductors in iron armored conduit or plain iron pipe. In order that there may be no further misapprehension on this point, however, it should be stated that throughout this discussion the writer has referred only to conduits for conductors carrying currents having an e. m. f. of not more than 300 volts.

But to get back to the earth and things that are of the earth, there appears to be at present little cause for fear regarding the ability of electrical engineers and manufacturers to produce insulation, that if used for low tension conductors placed in insulated iron armored conduits, will be a reasonably good protection against fire. The second paragraph of the letter from Cincinnati contains a sentence worded as a proposed requirement for iron conduit construction with which contractors might possibly have some slight difficulty in complying, viz.: "The piping must be electrically continuous and heavily grounded with a ground of carrying capacity equal to that of the largest wire in the system." It is probably safe to say that the ground of a conduit system is seldom of equal value for any considerable length of time, and even if it were possible to maintain indefinitely atmospheric conditions of equal density, it would be necessary to invent a conduit coupling that would permanently retain an electrical connection having a given current-carrying capacity. If anyone has knowledge of such an invention, it is his duty to make it known now, then after such a joint is perfected the permanent atmosphere should be advertised for.

It would be exceedingly interesting to hear from some of the electrical contractors who occasionally install conductors of from one to three million circular mils regarding this proposition to produce on their iron conduits, a ground connection, continuous the entire length of the tube and having current carrying capacity equal to that of the largest conductor of the wiring system. Let the contractors or engineers of the Astoria, Siegel-Cooper, St. Luke's Hospital or some other installations of about the same size, tell us how they would like to work under such a rule and how they would endeavor to comply with it.

The question of the strain on the insulation of a conduit being always constant at the bend seems to be a regular old stand-by, and is used, perhaps for want of a better argument, by almost every advocate of plain iron pipe, while almost with the same breath most of them claim that such pipe should have a thin coat of varnish, paint or enamel which, by their own argument, will not last in a bend while ten feet of wire are being drawn over it, and under the best conditions will not last nearly as long as the thick, strong, solid interior lining that is used at present, and which, if the pipe is large enough, will withstand the drawing in and out of all the conductors that will ever be placed in the conduits of which it is a part.

Most of the arguments that have recently appeared against the use of insulated iron armored conduit, refer directly or by implication to ancient history, viz.: an unsuitable lining, without sufficient mechanical strength and unable to withstand a temperature of more than 75° F., whereas the product of to-day is mechanically strong, will withstand without injury the drawing in and out of conductors as often as may be desired, and will be uninjured by a temperature of at least 500° F.

Engineers and contractors would do well to look into these matters carefully before placing too much reliance on the misleading statements of those who, unwittingly or otherwise, misrepresent the true condition of affairs, and who at least show a lack of familiarity with the character of the goods at present on the market. If it is wise to leave the selection of plain or insulated conduits to the discretion of the engineer, it is equally wise to leave every other question connected with electrical installations to the same discretionary power, and there should be only two underwriters' or other rules, viz.: Rule No. 1. All electrical conductors and appliances must be so installed as not to incur a fire risk. Rule No. 2. All electrical conductors and appliances must be so installed as to render personal injury impossible.

There is the sum and substance of the entire code with the details of construction "wisely left to the discretion of the engineer."

Of course it does not at present appear how such a proposition would apply on installations that are placed without the services of an engineer or how it would fare in the hands of an engineer who did not use discretion, but these are small details that would doubtless work out all right in time.

Manufacturers of anything on earth should certainly not be allowed to influence the decisions of Inspection Bureaus except as such bureaus may be influenced by having before them samples of every electrical appliance used under their rules, and assuming the knowledge that such familiarity with the market would imply their approval of any two articles, simply because they were to be found on the market or because one was cheaper than the other, though not as good, nor as safe, would seem to indicate almost anything under heaven except a "spirit of fairness."

Underwriters should be fair to everybody, but first of all to the insured public who pay the fire losses, for, although it may not occur to the average citizen, it is nevertheless a fact that fire losses are paid neither by the underwriters nor by the insurance companies, but by the insured public, whose premiums are large or small in proportion to their supposed fire risk, and who should be given, irrespective of the cost of materials, the best protection from fire which human ingenuity can devise. If "Bald Eagle" will look more carefully he will find, in all the wiring rules at present in existence in this country, many more inconsistencies than those he quotes, but if he employs the entire Lick Observatory, he will fail to find any rule which requires the use of a switchboard of any kind whatever.

As the rules now read he may assemble his apparatus on a switchboard, thereby greatly decreasing both fire and personal risk, or he may distribute his switches, instruments, etc., throughout a building, so that in case of trouble the building can be burned up before the operator can reach his controlling devices and indicators, much on the same principle as installing a boiler and engine in the sub-basement and putting the steam gauge and throttle valve up on the twenty-fifth floor. If there were good electrical reasons for the adoption of plain iron pipe instead of insulated iron armored conduits as raceways for electrical conductors, there would be no hesitation among fair-minded electrical men as to its use, but if it is to be used merely to reduce the cost of installations, at the expense of reducing their efficiency and insulation value, it can only retard the progress of the art without having anything to commend it in the premises.

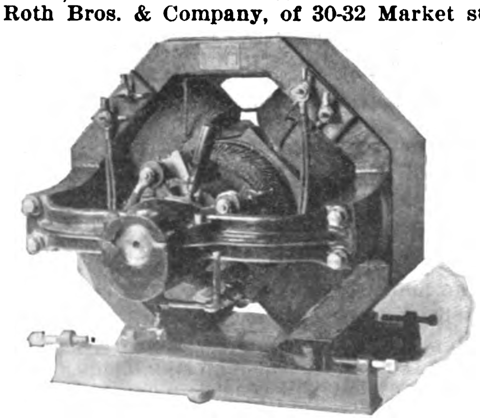
JIM CROW.

New York, Aug. 30, 1897.

NEWS AND NOTES

THE ROTH MULTIPOLAR DYNAMO.

ENCOURAGED by the unqualified success of their bipolar dynamos, now manufactured for a number of years, Messrs. Roth Bros. & Company, of 30-32 Market street, Chicago, Ill., have recently designed and placed on the market a line of multipolar generators and motors. These machines embody all the latest advances in dynamo construction and possess a number of special features, which merit investigation.



THE ROTH MULTIPOLAR DYNAMO.

The armature is of the hollow drum type, the core being built on a cast iron hollow cylinder easily removable from the shaft. The core discs, varnished for insulation before being

put together, are held between two solid cast iron end plates, the clamping bolts passing through the inner space of the hollow drum. This method of construction avoids holes through the core discs, thus giving a uniform magnetic path in the armature. The armature coils are wound on a form, taped with silk tape, varnished and baked before being placed on the core. The parallel grouping of armature construction is employed, which in connection with a special system of commutator connections greatly facilitates the repair of the armature.

In case a coil has to be removed, this may be done by simply loosening the two armature connectors of which the coil forms a part, whereas in general, in a four-pole machine at least one-half or even all the connectors have to be unsoldered.

The commutator has a liberal collecting surface as well as wearing stock and a large number of sections. Carbon brushes are used on all machines of 110 volts and over. The brush holders are of the tangential reacting type, the commutator surface moving in a direction opposite to the pressure of the springs. Each brush holder contains a number of square carbons, each pressed against the commutator by a spring. The tension of the springs may be adjusted and the carbons removed while the machine is running. These brush holders are among the simplest and most efficient yet devised.

The field frame is of the radial external pole type, which form has met with general approval during late years. The yoke is broad and entirely protects the field coils. The field cores are annealed wrought iron with circular section, which combines a maximum economy in the work of winding and the material of the field coils. The bearings are self-oiling, self-aligning and provided with oil gauge and cock.

From the foregoing description it will be seen that great care has been exercised in the design to produce a machine entirely reliable in operation and with all wearing parts interchangeable. The machines are wound either as generators or motors for 110, 220 and 500 volts, or special voltages. The generators are adapted for lighting, power transmission and electro deposition. When intended for lighting and general distribution they are accurately compounded and are self-regulating at constant speed. The rise of temperature of armature and field coils is well within the limit generally prescribed in dynamo specifications, and in regard to efficiency and operation the machines compare favorably with the best in the market.

BOSTON.—A school of electrical instruction has been established at the fire department headquarters, for the firemen, etc., under Drill Master Kinney, who is supervised by Mr. W. Brophy.

A TELEPHONIC AFFIDAVIT.—Record is made in the daily newspapers of August 31 of the receipt in New York City by telephone of an affidavit from Minneapolis. The sending of the affidavit by telephone was corroborated by a telegraph message sent for the purpose.

SOCIETY & CLUB NOTES

EDISON CONVENTION AT NIAGARA FALLS.

As already announced, the meeting of the Association of Edison Illuminating Companies will be held at the Cataract House, Niagara Falls, Sept. 14, 15 and 16.

The meetings of the convention will be held in the large ball room of the hotel. The sessions will be called to order at 10 A. M. each morning, commencing with Sept. 14, and 8 P. M. every evening, ending Sept. 16, the afternoons of the three days being devoted to the entertainments. The programme of the convention will consist of papers and discussions upon methods of charging for current, construction and practical use of the photometer as applied to the gas industry, storage batteries, economy in distribution of electrical energy, recent developments in electrical measuring devices, besides reports of various committees and Lamp Testing Bureau. The entertainments will comprise a visit to the power house of the Cataract Construction Company, a ride through "The Gorge" on the new electric road, tally-ho ride, etc., etc. A large number of favorable replies to the former notice of the secretary has already assured a very large attendance, in fact the convention promises to be the most successful one in many years.

PENNSYLVANIA STREET RAILWAY ASSOCIATION.

The above society held a good meeting at Allentown, Pa., on September 1 and 2, when nearly 100 members and supply men were in attendance. The following officers were elected: President, Robert E. Wright, Allentown; first vice-president, Frank Silliman, of Scranton; second vice-president, Dallas Sanders, of Philadelphia; secretary, S. P. Light, of Lebanon; treasurer, William H. Lanius, of York; Executive Committee, Robert E. Wright, Allentown; Simon P. Light, Lebanon; B. F. Meyers, Wilkesbarre; E. C. Felton, Harrisburg, and John A. Rigg, Reading. The convention will meet at Scranton next year. Dallas Sanders, of the Philadelphia bar, delivered an address on "Street Railway Legislation in Pennsylvania," exhaustively presenting the history of street railway transit and of the laws pertaining to this method of travel.

COLUMBUS, O.—The Ohio Association of Independent Telephone Companies, which includes some seventy-two companies in Ohio and Indiana, held a meeting on August 27, discussing plans for the extension of toll lines, etc.

PERSONAL

MR. A. J. GUERNSEY writes us that Mr. Henry Cottle has been appointed consulting electrical engineer of the Boston Fire Department, being already chief of the electrical division of the Public Buildings Department. He has had charge of the work of an electric light plant for the City Hospital, on which some $40,000 has already been spent.

MR. GEORG KIRKEGAARD, of Tompkinsville, L. I., has devised an electric trap for rats, which, with live chickens for bait, has disposed of as many as 123 of the rodents in a night. The chickens do not get used up, but the rats do. The trap doors are controlled by electricity.

MR. G. W. BEERS, of Fort Wayne, Ind., was a visitor to New York last week. He is interested in the independent telephone movement, and regards the outlook as bright.

MR. SETH C. ADAMS, on his retirement from the Bossert Electric Construction Company, Utica, has been presented by the factory staff with a handsome gold watch chain and charm as a remembrance of the pleasant relations that had existed.

MR. E. J. WESSELS, general manager of the Standard Air Brake Company, returned by the Lucania on the 27th of August after a three months' business trip abroad, during which time he visited the street railway convention in Hamburg. The Standard Air Brake Company have closed several important contracts for their various types of apparatus.

MR. L. M. ERB has resigned his position as manager of the Leavenworth, Kan., Electric Railway Company, with which he had been connected from the start. Mr. E. C. Combs is to act as manager for the present.

THE STOCK MARKET

GENERAL CONDITIONS BETTER AGAIN.

It has been thought by many that the recent advances in the price of staples and in stock quotations have been too rapid, but there is little evidence of the truth of that idea. On the contrary, the way in which the general strength is sustained is most remarkable. Wheat keeps around the dollar mark; iron and other staples have hardened in price; railroads report large increases in earnings, and the stock market has seen some sensational advances again.

During the past week, 94,778 shares of Western Union were sold at 93¼ up to 95¼. On sales of 41,310 shares, General Electric advanced to 39½, closing at 38⅛. American Bell Telephone has made a really phenomenal jump to 267.

JACKSONVILLE, FLA.—Plans are being prepared for an addition to the city's electric light plant. It is proposed to build an extension 28 x 30 feet to the south end of the present building. This will furnish ample room for the extra dynamo, if it shall be decided to make the extension.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUGUST 24, 1897.

Alarms and Signals:—

ELECTRIC BURGLAR ALARM. H. M. Dumas, Detroit, Mich., 588,695. Filed August 24, 1896.
The buildings are connected to a central office by a normally closed circuit and the signaling apparatus is placed in a shunt circuit.

ELECTRICAL INDICATOR FOR VALVES. W. J. Rickard, Philadelphia, Pa., 588,880. Filed October 31, 1896.
Details of construction.

Batteries, Primary:—

ELECTRIC BATTERY. Wm. Mills, Elizabeth, N. J., 588,591. Filed November 30, 1896.
Embodies an insulating bushing detachably secured to the zinc element.

ELECTRIC BATTERY. W. Mills, Elizabeth, N. J., 588,592. Filed November 30, 1896.
Similar to above.

Batteries, Secondary:—

ACTIVE MATERIAL FOR ELECTRODES OF ELECTRIC ACCUMULATORS. S. Hammacher, Berlin, Germany, 588,905. Filed August 28, 1896.
Contains a compound of lead oxid and a member of the pyrid in series.

Distribution:—

ELECTRIC LIGHTING SYSTEM. F. W. Lord, Boston, Mass., 588,683. Filed June 19, 1897.
Employs a two-way switch, and a two-way lamp socket connected at two corresponding points to the two-way switch, and connections from a third point on the socket and on the switch to the mains of the system.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. L. C. Rice, St. Louis, Mo., 588,602. Filed November 4, 1896.
Comprises a stationary armature, and field magnets, a rotating inductor magnet having poles of opposite polarity magnetically insulated from each other, and a casing completely enclosing them.

ARMATURE FOR INDUCTION MOTORS. A. L. Cushman, Concord, N. H., 588,692. Filed August 15, 1894.
Applies to armatures wound with magnetizing coils, each forming in itself a separate closed circuit not connected to an electrical source.

Electro-Metallurgy:—

APPARATUS FOR TREATING GOLD AND SILVER ORES. B Becker, Eupen, Germany, 588,740. Filed February 5, 1897.
Comprises a vat having a bottom of conical form, means for injecting liquid into the vat through its bottom and a distributing device to distribute the liquid laterally and spirally.

PROCESS OF MAKING LITHARGE OR PROTOXID OF LEAD FROM LEAD ORE. P. G. Salom, Philadelphia, Pa., 588,883. Filed June 29, 1897.
Consists in subjecting the ore to the action of nascent hydrogen electrolytically developed, producing thereby a spongy mass, then heating the spongy mass in the open air first at a temperature below the melting point of metallic lead and afterward to a higher temperature.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. T. Spencer, Philadelphia, Pa., 588,610. Filed November 16, 1896.
Enclosed arc lamp for alternating currents.

INCANDESCENT LIGHTING SUBSTANCE. W. Mahler, New York, 588,685. Filed July 10, 1897.
A mantle or hood composed of a large percentage of cerium oxid and a smaller percentage of lanthanum oxid.

ELECTRIC ARC LAMP. B. F, Greene, Sheridan, Pa., 588,822. Filed April 22, 1897.
Feed mechanism for enclosed arc lamps.

INCANDESCENT ELECTRIC LAMP SUPPORT. E. L. P. Wetmore, Marquette, Mich., 588,890. Filed March 13, 1896.
The lamp is suspended from a carriage movable on metal tracks connected with the current.

Miscellaneous:—

IGNITER FOR EXPLOSIVE ENGINES. L. Bly, Decatur, Ill., 588,629. Filed December 26, 1896.
Details of construction.

MEANS FOR SUPPORTING ROTATING SHAFTS. W. Stanley and F. Darlington, Pittsfield, Mass., 588,666. Filed May 5, 1897.
Comprises a rotatable shaft of magnetic material and a magnetic system producing a magnetic flux symmetrical and in supporting relation thereto.

ELECTRIC WICK LIGHTING DEVICE. H. Van Hoevenbergh, New York, 588,669. Filed May 5, 1896.
Igniter for central draft lamps.

ELECTRICAL KEG REGISTER. W. Kraft, Baltimore, Md., 588,797. Filed June 1, 1897.
Apparatus for counting kegs as they are taken from a cellar.

MEANS FOR MANUFACTURING CARBIDS. J. W. Keneval, Chicago, Ill. 588,866. Filed February 1, 1897.
Consists of a suitable casing within which are a pair of rotatable electrodes arranged in a horizontal plane, mechanism for rotating them and for connecting the electrodes with a source of electricity.

ELECTRICALLY OPERATED SHIP-CLEANING DEVICE. E. T. Thomas, New York, 588,933. Filed April 21, 1896.
Comprises an arched frame supporting electric conductors, a truck provided with wheels for holding a portable, suspended motor and tools operated by the motor.

Railways and Appliances:—

STATION INDICATOR FOR TRAMWAY OR OTHER CARS. H. W. Langschmidt, Brooklyn, and R. F. Le Brocq, New York, 588,701. Filed October 16, 1896.
Details of construction.

ELECTRIC CONNECTION BETWEEN RAILWAY RAILS. F. Marseilis, Peralta, Cal., 588,771. Filed May 13, 1897.
Consists of a curved elastic steel plate, having the ends bent to one side and adapted to engage with the rail ends and a means for clamping the plate in place.

ELECTRIC RAIL BOND. W. B. Cleveland, Cleveland, O., 588,791. Filed April 15, 1897.
Consists of an oblong frame formed from a laterally compressed coil of flat wire coiled to have its flat sides bearing against each other, and terminal heads and lugs cast upon the doubled ends of the frame.

TROLLEY WIRE HANGER. G. E. Johnson, Los Angeles, Cal., 588,923. Filed June 5, 1896.
Device for connecting the wires that can be applied without soldering the connections to either the supporting wire or the trolley wire.

Regulation:—

ELECTRICAL TRANSMISSION OF POWER. E. Lanhoffer, Mulhausen, Germany, 588,831. Filed June 20, 1895.
Means whereby the motors are capable of gradually altering their rotary speed, in contradistinction to a step-by-step variation of speed.

Switches, Cut-Outs, Etc.:—

ELECTRIC CUT-OUT. M. Marshall, Boston, Mass., 588,686. Filed May 29, 1896.
Consists in creating a substantially large air pressure by the heat generated by the melting of the fuse, and causing the same to pass in a smaller amount across the plane at a different point from that at which the pressure is created.

Telephones:—

COUNTING AND SIGNALLING APPARATUS. B. E. Waters, Brockton, Mass., 588,670. Filed February 8, 1897.
Designed to record the number of times a telephone is used.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUGUST 31, 1897.

Alarms and Signals:—

FIRE ALARM. J. W. Arnold, Otsego, Mich., 588,942. Filed April 29, 1897.
Comprises a tower and bell and spring actuated mechanism to sound the alarm when released by an electro-magnetic device.

MUNICIPAL SIGNAL SYSTEM. H. F. Eaton, Cambridge, Mass., 588,965. Filed November 24, 1888.
Adapted to operate an audible alarm or indicating signal for some of the signals and not others.

ELECTRIC ALARM AND CALL BELL. F. C. Jordan, Wadsworth, Ohio, 588,997. Filed January 11, 1897.
Employs a clock and devices whereby the connection of the contact-finger with the hour hand may be utilized to ring a series of bells at determinate places.

RAILWAY SIGNAL. C. W. Grant, Concord, Mass., 589,170. Filed November 19, 1896.
Employs coils placed along the road bed, operated by a locomotive on one section to sound an alarm in the cab of an interfering locomotive on another section, by means of induction.

Batteries, Secondary:—

STORAGE BATTERY. W. J. Still, Toronto, Canada, 589,042. Filed February 10, 1896.
The electrodes are formed of a rectangular spiral strip, the oxid being placed between the convolutions of the spiral.

Conductors, Conduits and Insulators:—

OUTLET BOX FOR GAS PIPES AND ELECTRICAL CONDUITS. W. J. Billings and M. Mauer, New York, 589,115. Filed June 7, 1897.
Embodies removable and interchangeable sides and a removable and interchangeable bottom plate.

PROCESS OF MAKING INSULATING MATERIAL. J. Gray and C. H. Case, South Manchester, Conn., 589,256. Filed May 16, 1896.
Consists in forming a mass of pulp to shape, heating the same in a bath of molten sulphur, and subsequently setting such article by immersion in a cold bath.

Distribution:—

MEANS FOR OPERATING GENERATORS AND STORAGE BATTERIES IN CONJUNCTION. W. Meredith and A. M. Hunt, San Francisco, Cal., 589,186. Filed September 8, 1896.
Comprises the combination of an auxiliary dynamo, storage battery and main dynamo, the armature of the auxiliary dynamo and the storage battery being connected in series and the two being in shunt, with the main dynamo.

Dynamos and Motors:—

BRUSH FOR DYNAMOS. F. J. Chapin, Birmingham, England, 589,162. Filed March 17, 1897.
Consists of sheets having the wires running diagonally and sheets having the wires running square with the length and breadth of the brush and with a wire center.

Electro-Metallurgy:—

APPARATUS FOR REFINING METALS BY ELECTROLYSIS. J. O. S. Elmore, Kapurthala, India, 589,251. Filed August 17, 1896.
Comprises a series of non-conducting frames carrying plates of crude material clamped together, and an electric circuit connected at its terminals to the lowest and uppermost sheet respectively.

APPARATUS FOR REFINING METALS BY ELECTROLYSIS. J. O. S. Elmore, Kapurthala, India, 589,252. Filed August 17, 1896.
Similar to above.

Electro-Therapeutics:—

ELECTRICAL BODY APPLIANCE. J. P. McGill, Chicago, Ill., 589,015. Filed February 23, 1897.
A flexible battery-belt comprising a plurality of continuously arranged galvanic couples.

Measurements:—

ELECTRIC METER. E. J. King, Fort Wayne, Ind., 588,999. Filed May 1, 1897.
Comprises field coils and a plurality of movable coils secured at an angle to each other upon a common axis within the field, connections

Miscellaneous:—

ELECTRICAL DENTAL FURNACE. C. A. Timme, New York, 589,-048. Filed March 14, 1896.
Composed of a casing of refractory material and removable heating plates independently connected with a source of electricity arranged at the interior of the muffle.

HARD BODY FOR RIFLING CHROMATED STEEL. F. Chaplet, Laval, France, 589,161. Filed September 15, 1894.
A very hard compound, consisting of carbon, titanium and silicium, in chemical combination.

ELECTRIC PIANO. J. L. Fulkerson, Kansas City, Mo., 589,347. Filed December 4, 1896.
Means whereby a piano may be operated from any desired point at any distance.

AUTOMATIC SWITCH FOR RAILROADS. L. A. Moore, Brooklyn, N. Y., 589,093. Filed April 10, 1897.
Embodies a weighted lever engaging with the switch-point to normally hold the switch open and electro-magnets to shift the lever when desired.

TROLLEY. A. O. Wyman, Turner's Falls, Mass., 589,109. Filed April 20, 1897.
Details of construction.

ELECTRIC CAR LIGHTING SYSTEM. F. M. Bennett, New York, 589,112. Filed January 4, 1897.
Comprises a dynamo actuated by the movement of the vehicle, a secondary battery, and a switch for directing the current to the secondary battery.

ELECTRIC HEADLIGHT. John Kirby, Jr., Dayton, O., 589,130. Filed February 15, 1897.
Details of construction.

Regulation:

ELECTRIC REGULATOR FOR DYNAMOS. W. H. Chapman, Portland, Me., 589,073. Filed April 4, 1896.
Voltage regulator. Details of construction.

Switches, Cut-Outs, Etc.

AUTOMATIC SWITCH FOR CHARGING AND DISCHARGING SECONDARY BATTERIES. A. S. Hubbard, New York, 589,-128. Filed October 23, 1896.
Details of construction.

TRADE NOTES & NOVELTIES

ELECTRIC POWER TRANSMISSION.

For ten or twelve years past the C & C Electric Company, of New York (works at Garwood, N. J.), have made a specialty not only of the manufacture of electric motors for every conceivable purpose, but have energetically been at work building up the electric power transmission business to such an extent that to-day they claim to have in operation more electric transmission systems than any other manufacturer of dynamos and motors. The C & C Company are still devoting considerable attention to making investigations of existing wasteful transmission systems in old manufacturing plants and submitting estimates of the saving which may be effected by the use of their power transmission apparatus. This company have recently taken several contracts for large systems of this kind and their years of experience in this work, as well the well known general excellence of their apparatus, insures that their customers will find entire satisfaction, as well as being able to effect considerable saving.

FULLER & CURTIS CO.

The Fuller & Curtis Co., Detroit, Mich., corner of Russell street and Boulevard, are the successors to the Fontaine Co. This new concern will manufacture the Fuller dynamos, motors and ventilating apparatus; also the Curtis hot blast apparatus for the heating of public buildings. The officers are Frank E. Kirby, president; Cameron D. Waterman, vice-president; Neil McMillan, treasurer; Rodolphus Fuller, secretary and manager, and W. H. Curtis, superintendent. They will be glad to receive inquiries as to all classes of dynamo and motor work, engines, boats, special apparatus, etc.

QUICK ELECTRIC COAL CUTTING.

The Jeffrey Manufacturing Company, of Columbus, Ohio, have received a report from James Cameron, superintendent of their No. 2 Western Coal and Mining Company's mine, located in Arkansas. Mr. Cameron states that at their mine with a Jeffrey electric machine, equipped with self propelling truck, they were able on August 13 to make 95 cuts in nine and one-half hours. This record was made by two of their men, all cuts being made with the same machine. This work was done in five rooms and two entries, and necessitated the changing of bits a number of times. It was necessary to load and unload the machine seven times. This run beats any record that has ever been made in the mine, and up to this date there has never been a report from any mine in the United States of such a record.

WARREN ELECTRIC AND SPECIALTY CO.'S LAMPS.

A contract for 10,000 lamps for the new Public Library, Chicago, has just been awarded to the Warren Electric and Specialty Company, Warren, O., who call attention to the fact in our advertising pages this week. They are pushing their business very briskly, and expect to do a very good trade. They offer lamps at low prices, and various candle-powers, in Edison, Westinghouse, Thomson-Houston, Brush-Swan, United States, Hawkeye, Schaeffer and Perkins bases, and will be glad to receive orders requiring prompt shipment.

ELECTRIC APPLIANCE CO.'S NEW CATALOGUE.

General Catalogue No. 12 of the Electric Appliance Company, of Chicago, has just made its appearance—a handsome, portly volume of nearly 600 pages, large octavo, bound in heavy red linen board covers, stamped on the side and back. It ranks easily as one of the foremost electrical catalogues of the day; in fact there are extremely few productions of the kind anywhere that could be put in comparison with it. The cuts number by the hundred, and are well displayed. All the various and endless specialties and standard goods are carefully grouped, and the fullest information is given in regard to sizes, prices, code words, etc. One admirable feature, indeed, of the whole book is the clearness of the arrangement and the type. The departments represented include all branches of electric light and power work, house electricity, railway work, telegraphy and telephony, and the classes of general supplies and miscellaneous material. The catalogue has been brought down to the latest minute by the insertion of special slips, etc., and constitutes a splendid and complete book of reference on supplies for the whole range of applied electricity.

STANDARD AIR BRAKE COMPANY.

The Standard Air Brake Company has just closed a contract for 60 air brakes for one of the Colonies. In addition to this, they have also closed a further contract for 15 complete air brake outfits, as well as several for some of the Continental cities. While General Manager Wessels, of the Standard Air Brake Company, was abroad, he appointed the following additional agents: Messrs. Dick, Kerr & Co., Ltd., the well known tramway supply people, at 101 Leadenhall street, London, E. C., who will hereafter be the sole agents for the United Kingdom. Also Messrs. E. H. Cadiot & Co., 12 Rue St. Georges, Paris, who have acquired the agency for France. It is expected that a good business will follow these appointments. The Bergsiche Stahl-Industrie, of Berlin, who represent the company on the Continent, have already inaugurated a very good business in air brakes.

SALE OF THE GIBBS ELECTRIC CO.

The Gibbs Electric Company, of Milwaukee, a small concern, some of whose apparatus has been illustrated and described in The Electrical Engineer, has, it is stated, been bought by the Westinghouse Electric Manufacturing Company, for the sum of $50,000.

CUYAHOGA SUPPLY CO.

Mr. F. W. Bunts, formerly assistant secretary and treasurer of the Walker Company, of Cleveland, Ohio, has bought out the Cuyahoga Supply Company, dealers in electric street railway and lighting supplies, and general selling agents for Eugene Munsell & Co. and the Mica Insulator Company in Cleveland and northern Ohio. Mr. Bunts will continue the business under the same title as formerly, occupying the offices at 102 Superior street. Mr. Bunts is a young man who has a large acquaintance in the city of Cleveland and vicinity, and his association with the electrical trade will, no doubt, bring to his company a large business. His leading lines, to which he will devote his special attention, will be the "Micanite" specialties, as manufactured by the Mica Insulator Company, of New York, Chicago and London, and Eugene Munsell & Co.'s India and Amber "Mica" in all of its various forms.

The electrical trade of Cleveland and vicinity will find it to their interest to consult the Cuyahoga Supply Company as to their wants, as a large stock of the above lines will be carried ready for immediate delivery.

THE ENCLOSED ARC LAMP manufactured by the Western Electric Company is meeting with favor among the direct current users of electricity. Features which are commendable are the shape of the globe and the means of support from the top, which prevent any possibility of a shadow caused by the globe. The lamp can burn singly on 110 volts, two in series on 220 volts, or five in series on 500 volts.

MEYSENBURG AND BADT.

This is the style of a new firm recently formed in Chicago, with headquarters at 1522 Monadnock Building. The members are Francis B. Badt, who is well known as one of the foremost electrical engineers in the West; and Mr. E. A. Meysenburg; the former being president of the corporation and the latter secretary and treasurer. The range of their operations will be quite large and will include the work of brokers, contractors and engineers in railway and general electrical equipment, appliances and construction. They will also act as experts in patent causes, and as consulting engineers.

ELECTRICITY IN NEW B. & O. SHOPS.

The erecting and repair shops of the B. & O. at Mt. Clare, in the city of Baltimore, which are the oldest shops in the United States, have been completely modernized. The locomotive-erecting shop has been rebuilt and is supplied with two 50-ton electric cranes, which lift the heaviest locomotives and move them to any point as though they weighed but a ton. The compressed air appliances are of the latest pattern and the cost of making the improvements will be saved in two years, as the new machinery accelerates the work, at a less expense than in times gone by.

ADVERTISERS' HINTS

THE WESTERN ELECTRIC COMPANY, Chicago and New York, advertise their new shadowless enclosed arc lamp adapted to burn singly on 110 volts, two in series on 220 volts and five in series on 500 volts. This lamp was recently described in our columns, and its many points of merit are doubtless remembered.

ARMORITE, the product of the Armorite Interior Conduit Company, Pittsburg, Pa., has been authorized by the New York Fire Department for use in all buildings in the territory under its jurisdiction. The facilities of their new factory are such that any order can be filled promptly.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., set forth a means of increasing dividends by the utilization of exhaust steam for heating purposes.

THE WARREN ELECTRIC AND SPECIALTY COMPANY, Warren, Ohio, have just been awarded the contract for 10,000 incandescent lamps for the new public library in Chicago.

THE PURITAN ELECTRIC COMPANY, Boston and New York, guarantee for the new Puritan alternating enclosed arc lamp 400 watts at 6 amperes and 100 volts.

B. O. ELLIS & CO., 136 Liberty street, New York, the electrical engineers and contractors, are devoting special attention to alternating current work.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, advertise felts for all electrical purposes.

THE ZAMEL ARC LIGHT METER has been approved by the National Fire Underwriters' Association.

NEW YORK NOTES.

MISSISSIPPI FLOODS.—A very interesting little book on this subject, by Mayor W. Starling, of Greenville, Miss., has just been issued by the "Engineering News," St. Paul Building, New York City, at the price of 50 cents. It treats fully and clearly of methods adopted or proposed for the control of these great risings of the river.

OGDENSBURG.—The street lighting contract for one year has been let to the Ogdensburg Power and Light Company, who are in reality the street railway company, at 19¾ cents all night, and every night, 107 lights. The company have water-power six months in the year. The bid of the Ogdensburg Gas and Electric Light Company was 24 cents per 2,000 c. p. lamp, 20 nights per month till 2 a. m., or 25 cents all and every night.

NEWARK, N. J.—The Crescent Electric Company has rented a large building on Market street, and, it is said, will, as soon as the needful machinery can be put in place, start it up in the manufacture of telephones and telephone appliances. The Best Telephone Company, of Baltimore, is said to have licensed the Crescent Company to manufacture machines. It is said 100 men will be employed in the new factory.

JOHNSON & MORTON, Utica, N. Y., are doing a large amount of electrical repairing, with a good staff, the latest machinery and moderate prices.

MAGNOLIA METAL COMPANY have called attention to the newspaper items of recent date relative to the alleged breaking into their factory at Sterling, N. J., and the issuance of a warrant in the same connection. They also request notice of the fact that their relations with H. G. Torrey and J. Gray Torrey were severed on April 15, and that these parties have no connection with their business.

LIVONIA, N. Y.—The Livonia Electric Company is extending its system, and is in the market for apparatus, including a good second-hand automatic 70 to 80 h. p. engine.

BOSSERT ELECTRIC CONSTRUCTION COMPANY, of Utica, N. Y., have their new, large and commodious factory entirely equipped with the newest and most improved machinery and are busy filling orders for their machinery.

YOUNGLOVE & GERE, Syracuse, N. Y., find an increasing demand for their new woven wire brushes.

THE DENNIS FLUOROMETER is being handled by the U. S. Electrical Supply Company, 120 Liberty street. This device has been illustrated and described in The Engineer. It enables, with the use of the X-ray, the exact location of foreign substances within the human organism.

AULTMAN AND TAYLOR MACHINERY COMPANY have issued under the title of "Big Boilers" a spicy pamphlet devoted to the discussion of the relative merits of their own boilers and those of the Babcock & Wilcox Company. The Cahall vertical boiler is also shown.

ONONDAGA DYNAMO CO., Syracuse, N. Y., report several recent installations. Among such plants may be mentioned a 35 k. w. generator direct-connected to a Watertown engine, for a large Sixth avenue, N. Y., retail store; a 35 k. w. generator, direct-connected, placed through Etherington & Co., their Philadelphia agents, and a 30 k. w. plant with Case engine, for the Lackawanna Brewing Co., Scranton, Pa.

J. B. COLT & CO., 115-117 Nassau street, New York, are exclusive agents for the Dolan patent automatic acetylene gas generators, for house and other lighting. The No. 3 generator with one charge of 1,000 pounds of carbide gives an equivalent of 80,000 feet of coal or water gas and will operate 40 to 160 lights. Special smokeless burners are also supplied. The cost is low and there is a big field for this apparatus.

A. L. BOGART COMPANY, 5 East Twentieth street, are successors to the firm of A. L. Bogart and have purchased all the patents, licenses, etc., owned by that well known old house. The present A. L. Bogart, well known in the electrical field, will be treasurer and general manager. W. B. M. Jordan is president, and D. H. Walker is secretary.

EDWARDS & CO. are making a full line of Rhumkorff coils, as high as 16 inches, and are selling large numbers in connection with the X-ray trade. They carry also, it is said, the largest line of different gongs in the country. They report business as rapidly picking up. Catalogue will be sent to any address on application.

NON-POLARIZING DRY BATTERY COMPANY give notice of a special meeting to increase their capital stock to $200,000.

THE PROCTOR-RAYMOND COMPANY, 444 Niagara street, Buffalo, N. Y., manufacturers of electrical specialties, have increased their capital stock and are developing new improvements on their standard articles. Mr. C. M. Proctor is president, Mr. John Gowans, secretary and treasurer, and N. H. Raymond, mechanical and electrical expert.

WESTERN NOTES

BELLS.—The severe competition in the manufacture of electric bells has resulted in lowering the grade as well as the price of the regular electric house bell. Realizing the fact that the trade demanded a better article in the line of an iron box bell, the Electric Appliance Company are placing on the market their Reliance iron box bell, which they claim is considerably better than anything in this line than has been placed on the market for some time. These bells cost more money to make, but are put on the market at an honest price, and to meet the demand of customers who are willing to pay a fair price for a good article.

WESTERN ELECTRIC COMPANY has started very successfully on its philanthropic career as an Art Union. Not long since it issued a fine picture of Niagara Falls, as a great source of power supply. It has now published, as a pictorial commentary on modern trade competition the famous picture, "The Rape of the Sabine Virgins," in which the virgins represent new contracts and the Romans personify the victorious Western Electric salesmen.

AMERICAN RHEOSTAT COMPANY, Milwaukee, Wis., report that business is very good with them, and that they have been running overtime in their factory. They state that their new "Perfection" motor-starting rheostat has met with considerable favor, and the orders for it are coming in fast. Their elevator and pump controllers are also in good demand, and among the orders recently closed by this company was one for 32 crane controllers.

ASHLEY, IND., has made a contract with Mr. H. McIntyre to remove the Garrett Lighting Company's plant to that place. It will furnish 45 arcs and 200 incandescents. The town furnishes ground, puts up the building, gives a contract for 10 lights for five years at $80 per light, with privilege of more lights at $65, and has the right to buy on arbitrated price at any time.

DETROIT, MICH.—The Jenney Electrical Works, lately burnt out at Indianapolis, are likely to move to Detroit, options having already been secured on the plant of the old Detroit Motor Company and another concern.

AUSTIN, NEV.—A fine Westinghouse plant has been installed for the Austin Mining Company by Mr. J. B. Flemming, electrical engineer. It comprises two 56 kilowatt generators, 250 volts direct current. A tunnel over 7,000 feet long with 2,000 feet of cross cut is lit up by 125 220 volt lamps, and about 250 are scattered around the silver mill. The yards are lit up by arc lamps.

ELECTRIC DELIVERY WAGONS IN CHICAGO.—Two electric delivery wagons made their appearance upon the streets here on August 21 and created a mild excitement. They are the property of Stevens Brothers, silk dealers, on State street. Four more will be put in use Monday. They are much like other retail delivery wagons except that they have rubber tires and are more beautifully finished. The vehicles cost $2,200 each, and are run by storage batteries. They can be run at any speed up to sixteen miles an hour, and are easily controlled.

MR. J. S. NOWOTNY, of the Nowotny Electric Company, Cincinnati, Ohio, reports business double what it was a year ago, and inquiries ten times as many.

JOHN A. ROEBLING'S SONS COMPANY has been formed at Chicago, with a capital stock of $5,000, by C. G. Roebling, W. A. Roebling, G. C. Bailey, F. W. Roebling, H. A. Gardner, F. E. Bradley and John W. Beckwith.

LINCOLN, NEB.—Mr. Frank Thomson, on behalf of the Triumph Electric Company, has closed a contract with H. Herpolsheimer & Co., to put a $2,000 plant in their big department store. Mr. Thomson has made several other large contracts in the city.

CLEVELAND, O.—Plans are on foot for the building of a big street railway system in Cleveland in opposition to the Consolidated lines. Most of the capital will be furnished by New York capitalists. Everything has been conducted with the utmost secrecy thus far. Mayor R. E. McKisson is said to be interested in the project.

ARDMORE, I. T.—The Ardmore Electric Light Company has been incorporated under the laws of Missouri with a capital stock of $50,000. C. A. Ross is president, and R. W. Hodge secretary. The plant consists of two Thomson-Houston dynamos of 1,000 lights of 16 candle-power; 100 horse-power John T. Noye engine, Atlas Engine Works boiler of 70 horse-power, and one mile of Phillips Insulated "O. K." wire. The power house is of brick.

NORTHVILLE, MICH., TELEPHONE COMPANY is starting up with a forty drop board, well filled. It has 25 miles of local circuit and 25 miles of toll line. The subscription rate is $1 per month, and the toll line rate is 10 cents. The apparatus is that of the Gilliland Company, of Adrian, Mich. Capital stock is $1,000. J. M. Burgess is president; M. A. Porter, secretary; S. E. Cranson, treasurer.

DAVID CITY, NEB.—W. J. Bell is now running a plant of arcs and incandescents, supplied by one 30-light Thomson-Houston machine and one 500-light General Electric generator. The engine is Sioux City Corliss, and there are about three miles of circuit.

BENTON HARBOR, MICH.—The Twin City Telephone Company was organized June 1, with a capital stock of $20,000, no bonds. W. A. Preston is president; R. Morrill, secretary; John Robinson, treasurer. It has a 400-drop switchboard, 337 subscribers, 400 miles of local circuit, 22 miles of toll line, and charges $16 and $25 per year. The system used is that of the American Electric Telephone Manufacturing Company. Forty-one miles of toll line are now projected.

SIEMENS & HALSKE ELECTRIC COMPANY, of America, are already feeling some of the good effects of approaching prosperity, as they have received quite a number of nice orders recently and are very busy at their large works in Chicago. The prospects of this well known concern doing a large business in the near future are excellent.

MR. THOS. J. AUSTIN, of the Cummings Conduit Company, Detroit, Mich., made a short visit to Chicago a few days ago.

COL. S. G. BOOKER, superintendent of the Phœnix Carbon Mfg. Co., of St. Louis, is a conspicuous example of well directed energy and thought and of ability to adapt one's business readily to the swift changes of industrial and commercial conditions in electricity. He has recently come forward with a vigorous notification of his intention to defend the company's rights in the carbon battery field, under their patents, and having made a specialty of battery carbons he expects very confidently to hold a large battery trade with their standard and popular goods. The Phœnix Company are also actively engaged in the manufacture of many other things in the line of carbons, particularly arc light points and motor brushes. Their plant is well equipped and under Col. Booker's management ever pushes forward into the branches of the art where carbon in any form is likely to be needed.

VOL. XXIV. SEPTEMBER 16, 1897. No. 489.

ELECTRIC LIGHTING

ARC POLES AND UNDERGROUND ELECTRIC LIGHT CONDUCTORS IN BUFFALO.

FOR some time past the Buffalo General Electric Co. has been carrying out extensive operations in the burying of its overhead circuits and already many miles of duct have been laid.

Camp tile conduits are used throughout, from 12 to 25 ducts being laid with 4 ducts on top layer opening into small distribution manholes 2 feet 6 inches in diameter. The main manholes average about 6 feet 6 inches by 7 feet 6 inches deep, with extra large ones at important junctions with old line of cement lined conduits. The manholes are of the well known double cover type with rubber gaskets and clamp, making a watertight joint. The outer covers are all cast hollow and filled flush with asphalt similar to that used in the streets, with the gratifying result of an entire absence of noise from wagon wheels passing over them. About 2¼ miles of this conduit line was laid on Main street and a connecting line down Court street to the station. A 20-duct line has now been continued down Court street to Niagara street, and thence out Niagara street about 3½ miles to meet the overhead power line from Niagara Falls.

The underground cables are No. 6 B. & S. copper with 3-16 inch rubber and 3-32 inch lead covering guaranteed for 10,000 volts working pressure, and were manufactured by the Safety Insulated Wire & Cable Company, of New York. The cable used in going up the inside of the iron poles has exactly

FIG. 1.—ELECTRIC LIGHT POLE, BUFFALO, N. Y.

the same insulation, but with two layers of jute in place of the lead covering.

The arc lamps are modified Thomson-Rice with special waterproof tops and protecting shield below to meet the globe, as shown in Fig. 1. The lamp hanger illustrated in detail in Fig. 2, is of special design to meet the severe strain imposed by the 6,000 or more volts difference of potential between the lamp and the iron pole, but a few inches separating them. With this hanger the double insulation secured is protected from the weather, the steel bolt terminating in the brass suspension hook being covered with moulded insulatinf material similar to that used in trolley work. This hanger and the porcelain mounted arc switch used in the base of each pole were tested by means of the high potential testing set recently developed by the General Electric Company with a pressure of 11,000 volts before being accepted. Samples of cable were also tested at this pressure and throughout the whole

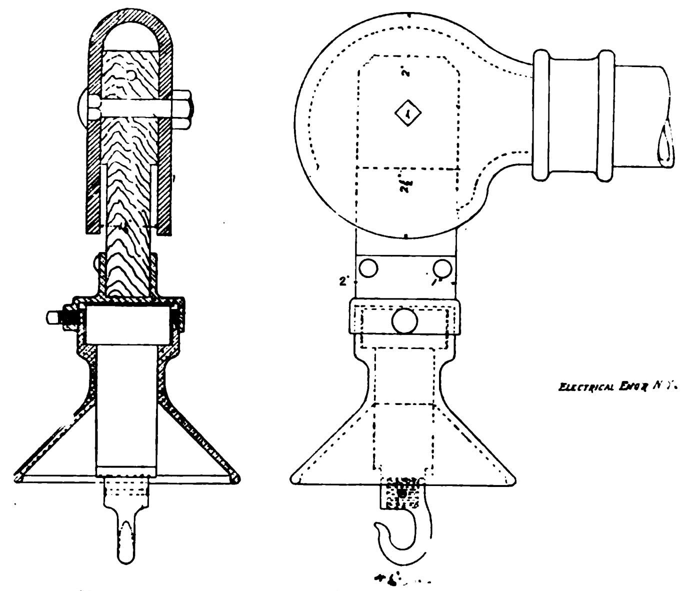

FIG. 2.—ARC LAMP POST SUSPENSION, BUFFALO, N. Y.

system the standard of work has been set at such a point that all material used must stand this pressure.

In pulling in the cables joints were avoided as much as possible by pulling from pole to pole and only making joints in the return cable in the main manholes. This policy of avoiding joints was carried out so well that in 28,000 feet of cable only 35 joints were made. This was made possible by locating a small 2 foot 6 inch manhole opposite each pole, the connection to pole being made by a 2-inch iron pipe with 18-inch radius bend going into the base of the pole.

The dynamos used are the new No. 12 Brush two circuit machines, each armature having thirty-two bobbins and four commutators, capable of giving out 6,250 volts and 9.6 amperes at 500 revolutions per minute. The subdivision of the commutator has already shown itself to be a marked improvement over the former three-commutator type.

ELECTRIC LIGHTING AT HAWLEY, PA.

The Hawley Electric Light and Power Co. is using the power of the Wallen Paupack Falls, a 420 h. p. S. Morgan Smith water wheel driving a 45 k. w. Westinghouse alternator and a 60-light Wood arc machine. There are nine miles of circuit and Fort Wayne converters are used. The officers of the company are W. L. Connell; president; W. K. Edgar, secretary and treasurer, and F. A. Harrington, superintendent. The company are in the market for carbons and 16 and 32 c. p. lamps, 100 volts; and will be glad to receive the catalogues of supply and fixture houses. Mr. Harrington informs us that there is an abundance of power for a manufacturing company, and that he can supply power at cheap rates.

A FEW FACTS FOR "E. E.", EXPERT EXCUSER, OF SOUTH NORWALK.

BY M. J. FRANCISCO.

IN the issue of The Electrical Engineer for September 2, there are nearly two columns of egotistical statements without facts, statistics or proofs of any kind to sustain them except the writer's high sounding title, "A. E. Winchester, E. E."—what a grandiloquent handle he has attached to his name, "E E."—Expert Excuser. Heretofore practical people have claimed that there was no excuse for the fraud, corruption and mismanagement of municipal plants, but here arises an "Expert Excuser" for all such business methods. We have been told repeatedly by this "Expert Excuser" that the results of Municipal Ownership were remarkable, especially in the City of Chicago. A report to the New York "Times" explains some of these remarkable characteristics: "The past week has brought revelations of the most barefaced frauds in the water-works department of the city. A conservative estimate gives $500,000 as the sum of which the city of Chicago has been robbed during the last two years; but in addition to direct stealing there can be no doubt that through lax methods of administering the department the city loses more than $1,000,000 each year, and that is a low estimate. Only very unsophisticated citizens can be surprised at any degree of corruption, no matter how great its magnitude, for the rottenness of the department has long been notorious. The details of the present investigation make manifest the most unabashed fraud and effrontery in the pursuance of criminal methods that indicate long familiarity. So numerous are the methods of defrauding the city that it is a difficult task to keep track of them as they come to light." A short time ago the same conditions were discovered in the fire alarm and electric lighting departments of this city, and proof was abundant that the city had been defrauded out of thousands of dollars; in the mean time, the city electrician, who had the business in charge, was loudly proclaiming (as our "Expert Excuser" is doing) that they were producing lights for one-half the cost of private companies. Here is the practical working of municipal ownership. Is it possible that the "Expert Excuser" is copying Chicago's example and applying it to South Norwalk, and that this is the reason for his squirming when the discrepancies in his reports are exposed? Suppose we reproduce a few of this "Expert Excuser's" figures and statements. On January 7, 1893, this "Expert Excuser" made a report to the mayor, as follows: "The plant has been erected in complete running order and been running since the forepart of October last; the expense attending the running of same ($1,657.46) has been paid from the amount appropriated by the city for the erection of the plant, leaving a balance on hand unexpended of $48.03." Again, in the report made in October, 1893, he repeats the statement that the balance on hand in February, 1893, was $48.03, while on page No. 5 of his report for 1896, he states, "Amount unexpended at starting up of plant was $2,500." In his 1893 report he stated cost of running plant, from time started to that date was $1,657.46—deducting this from the $2,500 would leave a balance on hand of $842.54, instead of $48.03, as he reported in 1893, thus leaving $795.51 unaccounted for, if his 1896 report is true. His 1893 report says they had $1,704.49 of the appropriation left when they started the lights, while in his 1896 report he says (page No. 5) there was $2,500 left when they started the lights. Which one of these reports is false? Did he lie in 1893, or was it in 1896, and what became of the $795.51 which has not been accounted for? Has our "Expert Excuser" adopted the remarkable plan shown by the investigation in Chicago, which he has extolled and admired so often? In his 1893 report to the mayor the following statement is made: "Expense of running the plant from October 13, 1892, to February 28, 1893—wages, $1,040.50;" while in report made October 12, 1893, he says: "Wages paid between October 13, 1892, and February 28, 1893, were $895," thus showing that if this last report is true he had charged the city $145.50 more than was paid for wages. What became of this $145.50; is it à la Chicago again? In his 1893 report this "Expert Excuser" stated that the "average candle-power per lamp was 1,600;" in the October, 1893, report they were given as averaging 1,400 c. p., while in 1896 they were 1,200 c. p. Now, in his last effusion he states that the candle-power "can only be obtained from the record of watts consumed." Thus showing that he knew when he made the statement of 1,600 c. p. in 1893 that it was false and was made for the purpose of casting discredit upon the local company who had previously furnished the lights. His plan was to make it appear that the candle-power under the city management was double that furnished per lamp under the old system by a private company. This "Expert Excuser" has a great deal to say about "honor, distorting facts and misrepresentation." A sample of his criterion of what constitutes honesty, fairness and unbiased comparisons will be seen in the following quotations from his published statement regarding the cost of lights when furnished by a private company and those under the municipal management. "Price paid to the private company for 81 lamps previous to October 13, 1892, was, for 800 c. p. lamp, per night, on moon schedule from dusk until 1 a. m., 22 cents. Cost per lamp, averaging 1,400 c. p. (here he has gone down 200 c. p. below his first statement) per night for year ending October 13, 1893, supplied from the city plant, 90 lamps in use 311 nights per year, no lights on bright moonlight nights, lighting time from dusk to 1:30 a. m., interest on bonds at 4 per cent. and depreciation at 2 per cent., 20½ cents per night." If his statement was true and they paid the private company 22 cents per night for 81 lamps, burned 311 nights in the year, the total cost would be $5,542.02. The city clerk reported to the mayor that in 1892 there was only $4,903.72 in all paid for electric lights and gas, showing clearly that our "Expert Excuser" made the amount $638.30 more than was actually paid the private company. The 81 lights furnished by the city plant burned on the moonlight schedules at price he claims they cost, 20¾ cents per night for 311 nights, would be $5,224.80, or $321.08 more than the same number of lights cost when furnished by the private company. The private company for $4,903.72 which the city clerk reports was paid them, not only furnished the 81 lights from dusk until 1 a. m., but for 7½ months of the year lights were burned every night and all night, thus giving the city about 80,000 hours of service, which this "Expert Excuser" has not shown or credited to the private company in his comparison. Of course, this omission was not intentional on his part, as the high moral character and Christian integrity which this "Expert Excuser" assumes would preclude such methods. Still the comparison was published and used wherever it could be utilized in an argument against a private corporation. The same method was employed when a sewer was built for the electric light plant, costing $414.24. The expense was charged to the sewer account of the city (as shown by the city clerk's report), thus reducing the electric light account that amount. In this "Expert Excuser's" report to the mayor, March 6, 1893, the following statement was made: "Previous lighting of the city cost an average of $12.71 per night for 81 lamps of 800 c. p. each." In his comparison, previously quoted, "Expert Excuser" stated "that cost of lights furnished by the private company was 22 cents per night." Will the "Expert Excuser" explain how he can multiply 81 by 22 and have the product $12.71?

Another plan adopted by this "Expert Excuser" in reducing the cost of lights was when the wire or cable under the river was broken; they repaired it and charged the expense to additions and extensions, instead of repairs, where it belonged. "Expert Excuser" says "that so far as the South Norwalk plant is concerned the author knows nothing of his subject, never having honored it with a visit." This statement is on a par with his others. How could he tell where, when or how the writer spent his time? The author has, however, made three visits to South Norwalk since the plant was established, and has seen that wonderful fireproof station, containing 30 or 40 tons of soft coal, wooden benches, window frames, doors and gallery floor, oil, waste, desks, stairs and partitions—all fireproof, according to his statement; "therefore, no insurance is required." The fireproof soft coal "takes the cake." The author stated that with only 37 per cent. of the heat of coal utilized this "Expert Excuser" claimed the cost of producing the lights was about half that of private corporations who utilized from 60 to 65 per cent. of the heat of the coal. "Expert Excuser," to prove that the author's statement was incorrect, gave the report of the engineer who made the test, as follows: "The largest loss is in the boiler where but 37 per cent. of the heat of coal is utilized. Good average practice for this type of boiler is from 60 to 65 per cent;" thus proving the absolute correctness of my statement by the report of his own expert. It is immaterial what causes the heavy loss in the boiler as long as it exists, but it does show very plainly that "Expert Excuser's" report of cost of lights is not in accordance with the true facts, and that an effort has been made to show a condition of things under municipal ownership which does not exist. The author of this article stated that lawsuits had been entered against the city; "Expert Excuser" says "this is an absolute falsehood." At a hearing before the committee of the Connecticut Legislature, in March, 1897, Judge Stoddard and the Hon. J. B. Alling, of New Haven, Conn., stated to the committee that such suits were in progress and that they were the attorneys for the plaintiffs. One of the suits is against the

city for a direct violation of the laws of its own State, in its efforts to defraud the private company. After the public statement made by these gentlemen to this committee of the Legislature, this "Expert Excuser" has the cheek to state that it is an "absolute falsehood." All of the statements made by this "Expert Excuser" in the vaporing articles he has published are of the same character. Has this man a large vacuum in his head, or is he acting the part of a consummate knave? While the author does not presume to say, the public can judge for itself. "Expert Excuser" also poses as a philanthropist working without pay; still, he was paid $500 for superintending the installation of that little plant of 100 lights, being $5 a light; therefore, if he can induce some other city to adopt the plans he advocates, there will be a chance for him to pocket $500 more, and this may account for his zeal in advocating the system.

Does "Expert Excuser" desire any more of the discrepancies in his reports shown up? If so, I shall be pleased to accommodate him and can furnish a score more of his original mathematical calculations.

TELEPHONY AND TELEGRAPHY

THE ROYSE SYSTEM OF TRAIN TELEGRAPHY.

An ingenious system of train telegraphy has recently been devised by Messrs. C. D. Royse, of Greencastle, and W. A. Royse, of Indianapolis, Ind. This system is an adaptation of the common Morse system of telegraphy for use with only a single sliding connection with the main line. The great obstacle to overcome has been the fact that the continuous electric line necessary for telegraphing could not be broken and carried into a moving train. The Royse system overcomes this by the adoption of the well known principle of split circuits, with the addition of reversed batteries.

In the accompanying diagram, A represents the track of a railroad and B a third rail, which may be simply a small strip of bar iron, weighing not more than three or four pounds to the yard, or even less. This third rail is insulated from the ground, and is the main conductor of the system. Main batteries, M B, are connected in reverse order, that is, both zincs or both coppers are connected to the main line, and the other two like metals to the ground or rails. This would give an electric circuit with no current, on account of the fact that the potential would always be at zero. C is an ordinary telegraph key, which stands open at all times except when in use, and D is a relay of high resistance.

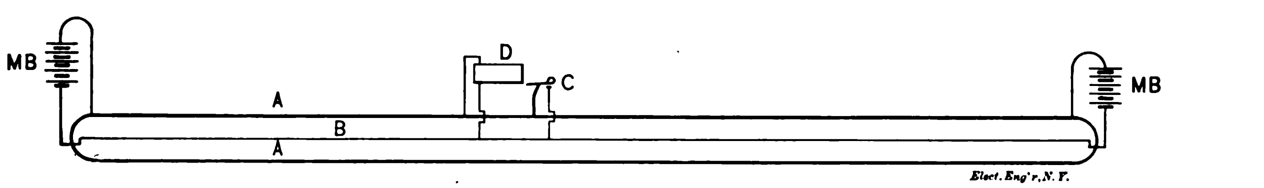
It will be noticed that both C and D have one side connected to the third rail and the other to the track rails or ground. The key is open and therefore gives no connection between the rails and wire, but the relay stands in this shunt or short circuit at all times. This relay is of high resistance, never less than 1,200 to 1,500 ohms, and this is increased as the number of trains on the road is increased.

By tracing from the two batteries to the relay connection with the main line and then through the relay, it will be seen that the effect of placing this relay in connection as it is, is to make two complete circuits, one from each battery to the point of connection, thence to the ground through the common outlet through the relay and its connections. The high resistance of this relay, coupled with the fact that the batteries are reversed and neutralize each other, prevents the grounding of the entire current through this relay. With a resistance of 500 ohms in this relay, or 1,000 ohms in each of two relays, or, in fact, a sufficient resistance in each relay, regardless of the total number to make the net resistance 500 ohms, not more than one-half of the current available in the batteries will be grounded through these relay connections. The current that passes through these relays when the keys are all open, closes them, but by reversing the contact points on the local side of the relays the sounders are made to close when the relays open, so that the sounders stand open when the line is not in use.

The effect of the closing of the key C is to give a direct connection between the main line and the rails without interposed resistance. This establishes a full current from the two batteries to the point of connection with the main line, and as there is no resistance, the entire current is grounded through the key. As the current passes through a number of conductors connected to form split circuits in inverse proportion to the resistance, it is plain that with a net resistance of 500 ohms in the train relays and a resistance of less than 1 ohm through the key circuit, less than 1-500th part of the current will continue to pass through the relays after a key has been closed. This will release the armatures of the relays, and they will open, this action closing the sounders. The relays will close again and the sounders open as soon as the key is opened. This is the main principle of the invention.

Station relays may be connected in the same manner as train relays, or they may be inserted in the main circuit just as the ordinary relay, but all keys must be connected as stated above, and all keys must remain open at all times when not in use. The reason for the latter statement is obvious; the key is not used to open and close the circuit, but is used to ground it.

It is claimed that this system of connections would be an advantage to the ordinary system of telegraphy. All circuit closers would be removed from keys and no operator could leave his office with the line open, as sometimes happens now to the great detriment of the service.



Royse Railway Train Telegraph System.

WESTERN UNION TELEGRAPH EARNINGS.

The Western Union Telegraph Company reports for quarter ended September 30, net revenue, 1897, estimated, $1,750,000; increase, $162,467; interest and sinking funds, $245,000; increase, $1,641; balance, $1,505,000; increase, $160,826; dividends, $1,216,975; increase, $25,014; surplus, $288,025; increase, $135,812; previous surplus, $7,647,541; decrease, $148,366; total surplus, $7,935,566; decrease, $12,554. The present quarterly statement includes the actual figures for quarter ended June 30 last, which completed the company's fiscal year. Actual results of the last two fiscal years, net revenue, 1897, $5,732,202; decrease, $165,778; interest and sinking fund, $975,501; increase, $1,544; balance, $4,756,701; decrease, $167,322; dividends, $4,792,854; increase, $25,049; deficit, $36,153 against a surplus in 1896, of $156,218; increase, $192,371; surplus, $7,603,694; increase, $156,218; total surplus, $7,567,541; decrease, $36,153.

HENRY C. ANDREWS, whose death was noted in the daily papers recently, was an active factor in the exploitation of the Drawbaugh Telephone Company in the days of the sensation caused by that enterprise.

MARYLAND TELEPHONE COMPANY has been formed at Baltimore, with a capital stock of $200,000, by C. Acklen, I. H. Gaither, C. C. Richardson, B. B. Hazlett and C. E. Fink, to make telephones and electrical supplies.

PORTLAND, ME.—Judge Webb, in the United States Court, has given a decision in favor of the Postal Telegraph Company, against the Portland and Yarmouth Electric Line, as to the protection of its circuits in Falmouth from trouble due to the trolleys.

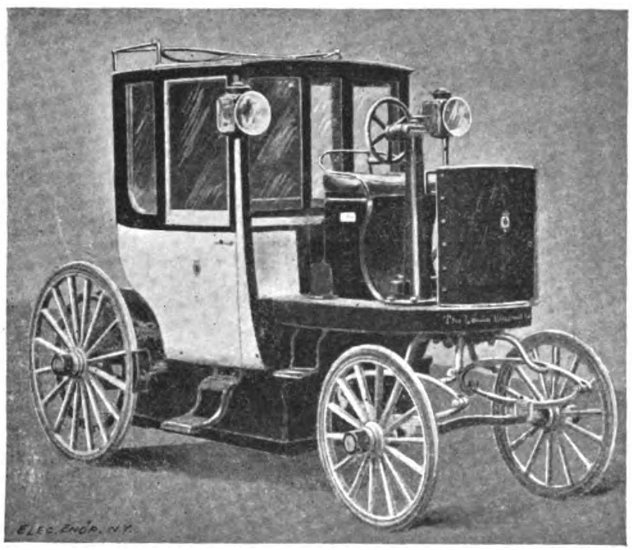
DIXIE TELEPHONE COMPANY has recently been organized with a capital stock of $2,000, with J. H. Northcut, Altamont, Tenn., as president; K. A. Pantolzer, Tracy City, vice-president; W. B. Holt, treasurer; M. Marugg, Tracy City, secretary and treasurer. The plant comprises a Palmer switchboard made by the Utica Fire Alarm Telegraph Company; boxes made by the Mianus, Conn., Electric Company, and Ericsson Swedish coal grain microphones. There are 52 miles of toll line and about 50 local subscribers.

ELECTRIC TRANSPORTATION

LONDON ELECTRIC CABS.[1]

WE had an opportunity this week of inspecting some of the London Electrical Cab Company's vehicles, and we were agreeably surprised with the care and thought which have been expended in their design. If the new company is not too much hampered financially by the agreements made with other concerns at the time of its formation, it would be fairly safe to predict for it a success, as, if electrically-driven autocars are to prosper, the lines followed by Mr. Walter Bersey in the design of these electric cabs would seem to be the right ones.

The battery used on each of the vehicles consists of a set of 40 E. P. S. traction type cells having a capacity of 170 ampere-hours when discharged at a rate of 30 amperes. It is estimated that on the level the current required, when the controller is placed at "full speed," is 24 amperes, and that on a fair incline, at about one-third that speed, this current is not exceeded. Steeper gradients require up to 30 or 35 amperes. The cut-out acts at about 100 amperes, and the driver is provided with a spare one in case of accident. The "afluidic" electrolyte which was to be used is still in its experimental stage. It is intended later to use this, instead of the usual dilute sulphuric acid, in the same type of cells. The E. P. S. Company guarantee the cells for a sum of 10 per cent. per annum of their first prices.



LONDON ELECTRIC CAB DRIVEN BY LUNDELL MOTOR.

The battery is carried in a tray, which is slung under the bottom of the cab by four suspension links supported by springs under compression, and the ordinary carriage springs again separate the cells from the vibration to which the carriage wheels are exposed.

The cabs are placed over a hydraulic table, on to which the tray of cells is wheeled on a light skeleton iron trolley. The table is then raised until the tray comes into the position in which it can be attached to the suspending links. The hydraulic table with the trolley is then lowered, and the cab is left free to propel itself away.

Fig. 1 shows the general external appearance of the cab. But for its color, which is a bright yellow, it resembles a one-horse coupé without the horse. There is only a single seat in the interior, well cushioned and comfortable, and of ample width for 2½ persons.. The tires are of solid rubber, and the running is very comfortable, and silent moreover, only a faint note from the motor being occasionally heard. There is an electric lamp in the interior of the vehicle, and the outside lamps are also electric. The steering is effected by the two front wheels, through ordinary worm gearing turned by a handle on the driver's right hand in the usual manner.

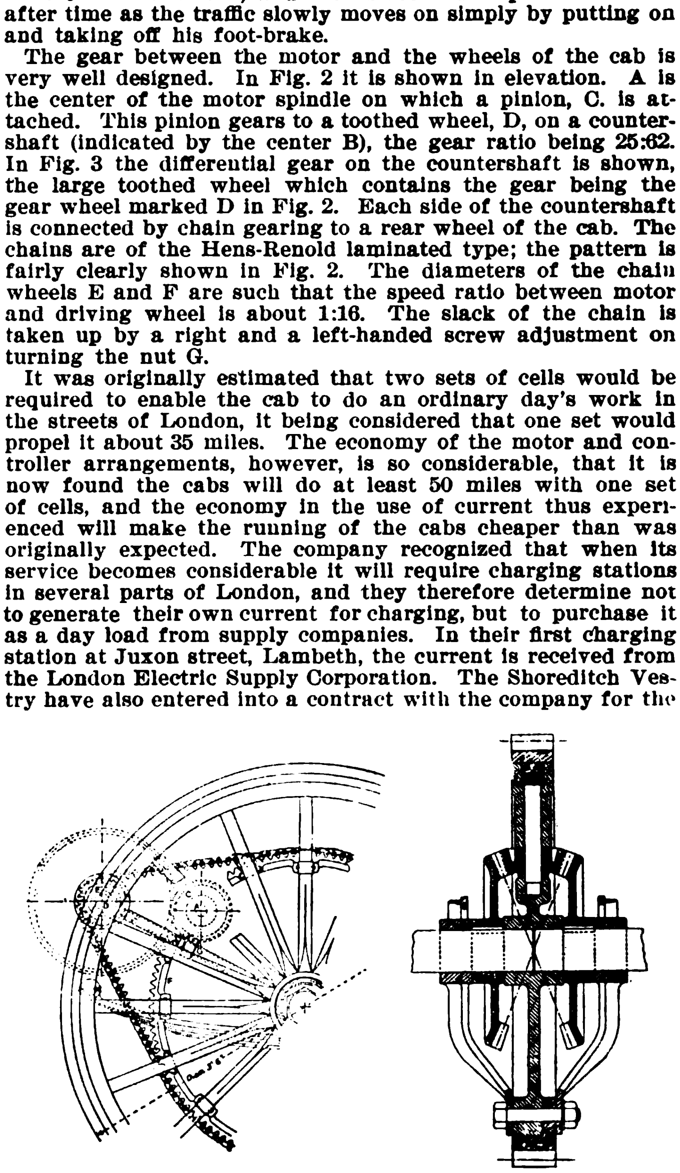
[1]London Electrician.

The motors have been specially designed for these cabs. They are of the Johnson-Lundell type, and supplied from America. The fields have two similar windings, and the armatures have also two similar sets of windings and two commutators. This doubly-wound motor is connected to a series-parallel controller of the usual American pattern in exactly the same way as the two motors of a tramcar would be connected to it.

The whole of the controller movements are produced by the use of one lever placed at the left-hand side of the driver's box. The removal of a plug beneath the driver's seat disconnects the controller from the motor and cells. The circuit from the accumulators to the controller and motor passes through a switch attached to a foot-brake, which can also be used for bringing the cab to a stop. This switch is arranged to break the circuit when the foot-brake is applied. It is therefore impossible for a careless driver to apply the brake whilst the current is still passing through the motor. The foot-brake has another advantage in the crowded London streets, for when moving in a block the driver can set his controller handle to slow ahead, and then start and stop the cab time after time as the traffic slowly moves on simply by putting on and taking off his foot-brake.

The gear between the motor and the wheels of the cab is very well designed. In Fig. 2 it is shown in elevation. A is the center of the motor spindle on which a pinion, C. is attached. This pinion gears to a toothed wheel, D, on a countershaft (indicated by the center B), the gear ratio being 25:62. In Fig. 3 the differential gear on the countershaft is shown, the large toothed wheel which contains the gear being the gear wheel marked D in Fig. 2. Each side of the countershaft is connected by chain gearing to a rear wheel of the cab. The chains are of the Hens-Renold laminated type; the pattern is fairly clearly shown in Fig. 2. The diameters of the chain wheels E and F are such that the speed ratio between motor and driving wheel is about 1:16. The slack of the chain is taken up by a right and a left-handed screw adjustment on turning the nut G.

It was originally estimated that two sets of cells would be required to enable the cab to do an ordinary day's work in the streets of London, it being considered that one set would propel it about 35 miles. The economy of the motor and controller arrangements, however, is so considerable, that it is now found the cabs will do at least 50 miles with one set of cells, and the economy in the use of current thus experienced will make the running of the cabs cheaper than was originally expected. The company recognized that when its service becomes considerable it will require charging stations in several parts of London, and they therefore determine not to generate their own current for charging, but to purchase it as a day load from supply companies. In their first charging station at Juxon street, Lambeth, the current is received from the London Electric Supply Corporation. The Shoreditch Vestry have also entered into a contract with the company for the supply of current at its second charging station, at the price of 1½d. per kilowatt hour.



FIGS. 2 AND 3.—DRIVING GEAR OF LONDON ELECTRIC CAB.

The cabs are to be fitted with integrating ammeters, arranged so that the driver can see by a glance at the dial what proportion of the charge of the cells he has already used.

FALLSBURGH, N. Y.—The Fallsburgh & Monticello Railroad Co. expect to extend eleven miles to Neversink Flats and Grahamsville. They have six miles of track, four cars and one motor car for freight; with two 200 h. p. boilers in their power

house and two 150 h. p. engines. The offices of the president, Mr. B. Van Steenburgh, are at 53 Broadway. The company has a capital stock of $75,000.

THE DE BAUSSET AIR-SHIP.

FOR a number of years past Dr. A. De Bausset, of Brooklyn, has been working at the problem of providing an airship which should be capable of carrying an appreciable load and be completely dirigible at the same time. Dr. De bausset purposes to construct of steel a cylinder 774 feet long and 144 feet in diameter. This would hold, roughly estimated, 10,000,000 cubic feet of air. A cubic foot of air weighs 0.08+ of a pound. By pumping out the air and creating a vacuum, 400 tons of weight would be disposed of. In other words, the displacement of the airship would be 400 tons.

The airship, built of material strong enough to withstand the enormous pressure from the outside, due to the vacuum within, would weigh 250 tons.

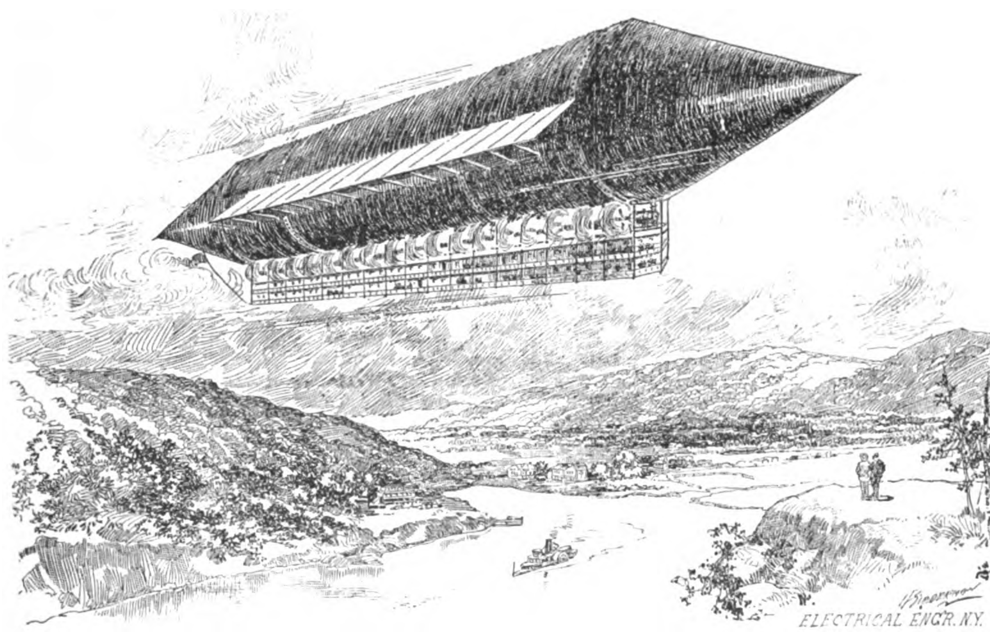
The following data give the principal dimensions and weights:

Length of cylinder, cone-shaped at both ends, feet..	774
Diameter, feet	144
Displacement, volume, cubic feet	10,000,000
Displacement, weight, tons	400
Weight of steel for cylinder and cones, tons	215
Weight of car beneath, tons	35
Weight of electrical appliances, machinery, etc., tons	33.4
Weight of air remaining within cylinder as ballast, tons	66.6

The air pumped out equals 333.4 tons, leaving an external pressure of 12.25 pounds per square inch. The total weight of materials, machinery and air in reserve is 350 tons, which, deducted from the capacity of the cylinder, 400 tons, leaves an ascensional lifting power of 50 tons.

The partial vacuum will allow an amount of 66.6 tons of air in reserve to counteract atmospheric pressure of 2.4 pounds per square inch of area. Part of this ballast will be pumped out in the common reservoir if an extra load is to be carried, or for any emergency.

Suspended from the cylinder, as shown in the accompanying engraving, is a car, which will carry the engines, dynamos, electric motors, propellers, etc. The airship will be steered by changing the angle of the propellers, which will be pivoted with that end in view.



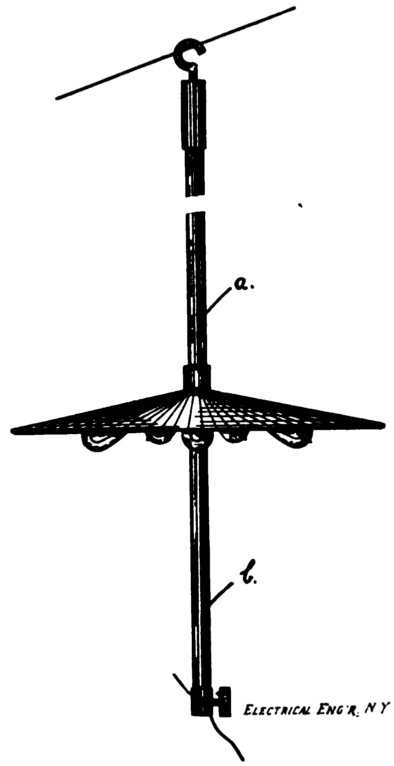
THE DEBAUSSET DIRIGIBLE ELECTRIC AIR SHIP.

All details, such as motive power, etc., have been carefully estimated. A Congressional committee, after looking into the plans, thought so well of them that it recommended the appropriation of $150,000 (House bill 5,717) to construct a ship. The bill, however, was pigeon-holed in the Senate Committee on Naval Affairs.

HANDY ELECTROLIER FOR TROLLEY TRACK NIGHT REPAIRS.

BY N. M. HOPKINS.

THE accompanying little sketch shows an arrangement of lamps in combination with a pole and reflector, well adapted for track lighting during night repairs or alterations.



ELECTROLIER FOR RAILWAY REPAIRS AT NIGHT.

The illustration is self-explanatory; the wire a b is connected to five 110 volt lamps in series for a 550 volt street railway service. The connection with the rail is made by a clamp, or in any other suitable manner by means of a flexible cable. The device is in use in Boston, the only city thus equipped which has been noticed by the writer.

PITTSBURG, PA.—Col. A. H. Swan, of Ogden, Utah, F. L. Pushaw, of Boston, and others are to organize a local plant, it is said, to cost $100,000, for the manufacture of a new electric traction brake upon which they control the patent.

THE PRESENT TENDENCIES OF ELECTRIC TRAMWAY TRACTION.[1]

BY J. G. W. ALDRIDGE, A. M. INST. C. E.

TRAMWAY work is at the present time, and has been for some years past, characterized by an increasing use of mechanical traction systems. The reasons for this are obvious and self-evident. It is, however, worth while to look into the considerations that, so far as electric traction is concerned, have caused one system or another to grow into favor, noting also the inherent qualities or attributes of each, which must have an effect on future developments.

The United Kingdom has practically 130 miles of electric tramway at work or under construction; of this length 103½ miles are operated on the trolley or overhead wire system, 15¾ miles by means of a third rail conductor, 6 miles by means of storage batteries, and only 4 miles on the underground conduit system. These proportions may be taken as fairly representative of other countries also, as far as can be ascertained.

They seem likely to be maintained or even increased in favor of the overhead wire system, unless radical improvements can be made in the direction of a cheaply built and maintained conduit method, or more durable and light accumulators for placing direct upon the car. Objections to the overhead trolley wire system are almost entirely æsthetic, but at the same time have such great weight and force that every incentive is offered to the genius of invention to make improvements in other directions.

The ordinary underground conduit with open slot is most expensive to instal and troublesome to maintain efficiently; it cannot be built for less than 10,000l. or 12,000l. per mile. Even its latest form (consisting practically of an underground trolley wire) must require an outlay of nearly double the cost of an overhead wire system.

Closed conduits with surface contacts usually operated by means of electromagnetic switching devices in boxes under the street level are complicated, and it is to be feared are unreliable. The great weight of lead required on each car for accumulator traction means practically that the live paying load can never reach 25 per cent. of the gross weight of loaded car; whilst the combinations of trolley wire and battery, attempted on systems like those of Hanover and Dresden, are obviously ill-designed, the dead weight of battery being carried throughout the entire journey, though it is not required for part thereof.

The overhead trolley wire system therefore appears likely to come into still greater use than has already been the case, if only on the ground of economy; but in view of its admitted defects, the author has worked out an alternative method which avoids the erection of trolley wires along the streets above the tracks.

POWER REQUIRED OF DRIVING VEHICLES.

SOME interesting tests have recently been undertaken in France with regard to the power required for the propulsion of vehicles, fitted with wheels with ordinary iron rims and pneumatic-tired wheels, and the results showed a marked all-round advantage by the pneumatic wheels. A table of the pull required, reduced to kilogrammes, shows the results with different roads and different loads:

	Iron. Rims. Kilog.	Pneumatic. Tires. Kilog.
Snow.		
Empty vehicle, walking	17.86	11.45
Empty vehicle, trotting	29.60	15.27
150-kilogramme load, walking	17.83	12.71
150-kilogramme load, trotting	31.17	17.96
Wet Roads.		
Empty vehicle, walking	16.00	10.50
Empty vehicle, trotting	19.55	12.97
150-kilogramme load, walking	17.30	12.43
150-kilogramme load, trotting	23.00	14.16
New and Dusty Roads.		
Empty vehicle, walking	17.42	14.05
Empty vehicle, trotting	20.41	15.95
300-kilogramme load, walking	20.75	19.14
300 kilogramme load, trotting	29.70	16.40

Experiments were also made with various pressures in the tires—3 and 4½ atmospheres—but there did not seem to be much difference between the two.

[1]Read before the British Assoc. at Toronto.

AUTHORIZED SPEEDS OF TROLLEY CARS.

The rates of speed for street railway cars as established by the ordinances and franchises in different cities are as follows in and out of city limits: Albany 12 miles per hour, Binghamton 12 miles, Brooklyn 6, 8 and 10 miles, Buffalo 12, 15, 18 and 30 miles, Elmira 7 and 15 miles, Rochester 6 and 12 miles, Allegheny, Pa., 15 miles, Omaha 10 and 15 miles, Grand Rapids 7 and 15 miles, Washington 6, 12 and 15 miles, Boston 7, 10 and 12 miles, Denver 9 and 15 miles, Des Moines 8 and 12 miles, Columbus, O., 8 and 14 miles, Dayton, O., 10 miles, Evansville, Ind., 12 miles, Kansas City 12 miles, Louisville 10 and 12 miles, New Haven, Conn., 10 and 12 miles, Paterson, N. J., 10 and 15 miles, Providence, R. I., 9, 10 and 12 miles, Rochester 7 and 15 miles, St. Louis 10 and 12 miles.

SOME FURTHER EXPERIMENTS ON THE X-RAY.[1]

BY T. C. PORTER.

MESSRS. A. VOSMAER and F. L. ORTT have arrived at the conclusion that the X-rays are more or less perfectly discharged particles.[2] Others—Sir W. Crookes, for example—have suggested the material nature of the rays, and the only novel point in the paper referred to seems to me to be that the rays owe their greater or less penetrative power to the fact that they are particles less or more free from electric charges. If this were the case, it seems scarcely possible that the particles could pass as freely through, and in the neighborhood of, a conductor when charged as when uncharged. If the particles were completely without charge, it is true they should be equally affected by a conductor first charged positively, and then with an equal negative charge. On the other hand, if the particles were positively charged, they would experience stronger attraction to a conductor negatively electrified than to the same conductor equally positively charged; and the same, mutatis mutandis, may be said if they are negatively charged.

The effect one might expect is that the uncharged particles would at first be attracted by a charged conductor, and then repelled from it, if they acquired part of its charge, in which case the photographic image of the uncharged conductor produced by the X-rays would be modified in intensity if not in form[3]—probably in both.

If, as Messrs. Vosmaer and Ortt suppose, the "rays" are dis-electrified by striking against the charged anode inside the tube, it is difficult to see why they should not be re-charged, and therefore act like other charged particles, if they strike against an electrified conductor outside the tube, especially if the potential of the external conductor be as great or greater than the potential of the internal. Indeed, the authors of the paper admit this; and if it is true, one might reasonably expect some such action as I have sought for.

I therefore thought it would be, at any rate, worth trying experiments to see if the X-ray photograph of a conductor, such as of a small plate of aluminum (with carefully rounded edges), differs according to (1) whether it be charged or not, and (2) whether it be charged positively or negatively.

According to the paper the X-ray particles are to be considered free from charge when they completely discharge a charged insulated plate, without afterward imparting to it a charge, and the focus tube I used in all these experiments was one which gave rays of this description.

In the first set of experiments two small squares (A and B) with rounded edges, cut from the same piece of sheet aluminum, and one-thirtieth of an inch in thickness, were arranged in the same horizontal plane beneath the focus tube placed symmetrically with respect to the anode of the tube, so that the line joining the centers of the squares was in a direction at right angles to the line joining the center of the anode and the center of the cathode mirror. Below these small squares, and resting on a thick block of paraffin, was placed the photographic plate (all the plates used belonged to the same batch)—

[1]London Nature. [2]See Elec. Engr., Sept. 9.

[3]The alteration in form, and to a certain extent intensity, would depend partly on the velocity with which the particles were traveling. I do not remember reading of any determinations of the velocity of propagation of the X-rays; but if this remains very high over great distances, as it seems to do, it would appear very unlikely that the rays consist of material particles.

the Ilford special rapid, and all the plates of each set of experiments were developed together in the same dish). The tube was worked by a large coil, giving six-inch sparks, and A and B were electrified when necessary by wires from the poles of a Wimshurst machine with leydens giving seven-inch sparks between the knobs when used in the ordinary way. The duration of each exposure was timed by a stop-watch in each case, and was as nearly as possible the same for each set of experiments.

A blank experiment in each set, in which the plate, wrapped in dark paper (the same number of folds in every case), was exposed to the radiation from A and B without the Röntgen rays, proved that no photographic effect was produced by their electrification by the Wimshurst.

Exposures were then made as follows: (1) A and B both earthed by a wire soldered to a gas-pipe. (2) A positively, B negatively electrified. (3) A negatively, B positively electrified. (4) A positively, B to earth. (5) A negatively, B to earth. (6) A and B both earthed.

Development showed that the electrification of A and B was without effect, either absolute or comparative.

Since in the above experiments sparks passed between A and B when their difference of potential exceeded an amount far less than that which could be given by the Wimshurst, and it seemed possible that a stronger charge might still yield some indication of a difference, one of the aluminum squares was removed, and the other shifted till it was immediately beneath the anode, and a second set of experiments was made in a rather different way. In each pair of exposures the same plate was used, each half of the plate being protected, whilst the other half was exposed by a thick slab of plate glass—proved by experiment to allow no developable action of the X-rays to pass through it during the time of exposure used. The experiments were as follows:

(1) A blank experiment without the X-rays in which one-half of the plate was exposed, first to A charged positively to the full power of the Wimshurst, and then the other half to A charged negatively in the same way. The result showed there was no developable action. (2) 1st half X-rays only, then an interval of rest (the same interval being allowed between every experiment), then the 2d half to the X-rays only; this was done to see how the emission of the tube varied. (3) 1st half A positively charged, 2d half X-rays only; A to earth. (4) 1st A negatively; 2d A to earth. (5) 1st A positively; 2d A negatively. (6) 1st A insulated; 2d A to earth. (7) Same as (2). (8) Same as (1).

The whole of this series was repeated, using the contents of one box of Edwards's isochromatic plates. Development showed no action which could be attributed to the electrification of A.

In the third series of experiments A was connected by a wire first to the katnode loop and then to the anode loop of the focus tube, and radiographs were taken comparing the effects of this treatment with that of earthing A; but these, too, gave no indication of any increase or decrease of the X-rays reaching the plate, nor of any re-distribution of the rays.

In the fourth set the photographic plate was placed on an ordinary discharging table, and brush discharges, and afterward thick sparks were passed between the poles of the discharger, and the radiographs developed; but they showed no traces whatever of any effect of the sparks.

I, therefore, conclude that the radiograph of a conductor (though it is true I have only tried aluminum and brass) is not sensibly altered by even powerful electrification, nor are the rays altered in force or direction in passing through air in the neighborhood of a powerfully-charged conductor, nor even through air which is being subjected to a powerful disruptive discharge.

This seems to me to make it more difficult to believe that the X-rays are due to particles, whether totally or partly devoid of charges of positive or negative electricity.

LITERATURE

THE ELEMENTS OF ELECTRO-CHEMISTRY, TREATED EXPERIMENTALLY. By Dr. Robert Luepke. Translated by M. M. Pattison Muir, M. A.. Philadelphia, 1897. J. B. Lippincott Company. 223 pp.; 8½ x 5½ in. 54 illus. Cloth.

This translation of the second edition of the popular handbook of Dr. Luepke, gives a complete review of electro-chemistry, together with descriptions of the more important electro-chemical processes and problems. In its present state this book serves both as a guide for the student as well as a ready reference for the expert.

LETTERS TO THE EDITOR

TEST OF THE THOMSON RECORDING WATTMETER.

THERE appears in a paper by Mr. Ricks, read before the British Association at Toronto, a description of certain tests made in my laboratory on various electric supply meters. From the results there given it would appear that the Elihu Thomson energy meter (or so-called "recording wattmeter") when used at ordinary temperatures reads about 13 per cent. too low at one-tenth full load, and that, when measuring ordinary direct current loads, an increase of temperature of 30 degs. C raises the speed of the meter by about 11 per cent.

I have no reason to doubt the accuracy of Mr. Ricks' results, indeed the very careful and painstaking way in which he carried out the investigation described in his paper leads me to think it highly probable that the figures and curves which he publishes do really record the behavior of the meters which he tested. But, during my recent visits to the works of the General Electric Company, at Schenectady, and at Lynn, I have become convinced that the particular meter which was lent Mr. Ricks by the British Thomson-Houston Company for testing can not be regarded as a sample of the instruments which are now being manufactured in large numbers.

From his tests of the Thomson meter Mr. Ricks states, "It may, therefore, be surmised that the coefficient" (of change of resistance with temperature) "of the pressure coil is very much less than that of the copper disc." To construct an energy meter with this difference in the temperature coefficients is, of course, quite wrong scientifically, and Professor Elihu Thomson tells me that in his instructions he has emphasized the fact that the temperature coefficient of the pressure circuit should be equal to that of the copper pressure disc. As a proof that this condition is really fulfilled in the Thomson meters constructed in the States various curves have been shown me, from which it appears that, at ordinary loads, a change of 40 degs. C in the temperature of the meter alters the constant only 3½ per cent., instead of by the 11 per cent. found by Mr. Ricks.

Further, I have watched tests being made on one of these meters at Lynn at temperatures of 60 degs. C, and at 24 degs. C. The meter in question was a 50 volt 15 ampere meter, and, when tested at 52 volts and 11.75 amperes, that is, at about three-quarters of full load, there was only 1 per cent. difference between the results obtained at these two temperatures although they differed by 41 degs.

Next, as regards the difference between the value of the constant of this type of meter at low and high loads it would appear from the curves which have been shown me recording the results of various tests, that with some specimens there is practically no appreciable difference in the value of the constant anywhere between full load and one-twentieth full load, while with other specimens the constant is about 2 per cent. higher at one-tenth of full load than at full load. These are very different results than those obtained by Mr. Ricks with the meter lent him for testing, for he found that the constant at full load had to be increased by 19 per cent. to make the meter read correctly at one-twentieth of full load.

Some hurried tests at various loads were made in my presence here, of the meter already referred to. The results at low loads were not very satisfactory, as the meter armature turns very slowly, of course, at small loads; and time pressed, as the factory was on the point of being closed for three days. Hence we had to content ourselves with timing one revolution only of the armature instead of waiting to take many, as was done in the very much more accurate tests carried out by Mr. Ricks. But it seemed clear that the variation of the constant between full and one-thirtieth of full load was not as large as was found by Mr. Ricks between full and one-twentieth of full load.

Hence, I conclude, both from the curves of previous tests, as well as from the tests which I saw carried out, that the Elihu Thomson meter tested by Mr. Ricks had not merely a much higher temperature coefficient than meters constructed at Lynn, but possessed a greater frictional resistance, or had "an initial energy coil" which was not powerful enough.

Lynn, Mass. W. E. AYRTON.

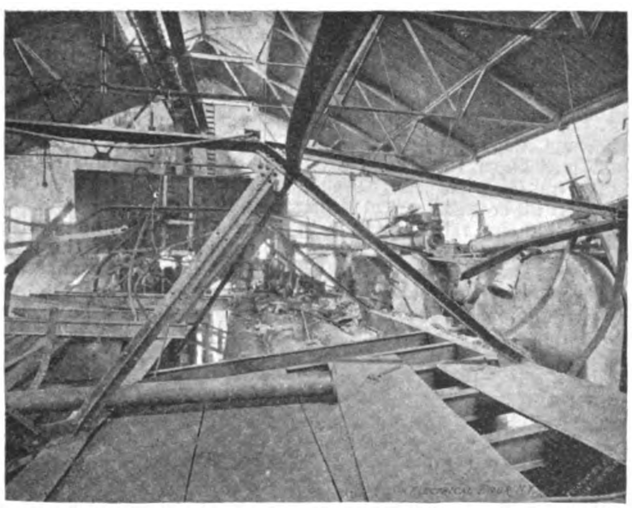
MECHANICAL

A TEST OF THE ABILITY OF BOILERS TO STAND OVERLOAD.

BY FREDERICK A. SCHEFFLER, M. E.

IT has been interesting to note the record in a recent issue of The Electrical Engineer of the curious and unusual accident in the Edison station at Paterson, N. J., the promptitude with which it was met, and the conditions of test and strain that it threw upon the apparatus. Mention has been made of some of the circumstances and results, but there are others to which I believe engineers will also be glad to have their attention directed, bearing as they do upon some of the most vital and essential details of central station work.

The Paterson boiler room, it will be remembered, is equipped with a battery of six 450 h. p. Stirling water tube safety boilers, in the rear of which is located an economizer furnished by the Fuel Economizer Co. Over the firing room was placed a large coal storage bin, built of sheet steel and channel beams and angle iron; the whole bin being sustained by riveted columns extending from the bottom of the coal bin to the floor, the upper part of the coal bin being much wider than the base of same projected over the top of the boilers. At the time of the accident this coal bin contained in the neighborhood of 1,000 tons of buckwheat coal, and it extended from one end of the boiler room to the other. The coal was apparently equally distributed throughout the bin. The coal was delivered to the bin by a complete coal conveying apparatus, furnished by the Hunt Company. Each boiler was furnished with a main steam outlet 10 inches in diameter, the pipe connections being extra heavy wrought iron. The outlets from each boiler ran to a 12-inch main steam header immediately over the top of the smoke connections, this pipe extending the full length of the boiler room. The accident consisted in, first, the giving way of part of that side of the coal bin not adjoining the boilers, permitting a large quantity of coal to be precipitated on the floor of the boiler room, entirely filling up the pump pit, in which fell at least 50 tons of the coal, and eventually this whole side parted. This threw the unbalanced weight on the opposite side of the coal bin nearest the boilers, thus causing this entire side of the coal bin, together with about 400 tons of coal, to be thrown forcibly on top of the boilers and steam connections. At least 100 tons of steel girders, plates, angle irons, etc., besides the coal, was precipitated on top of the boilers. There were but two of the boilers in operation at the time and an additional one had the fire banked ready for being put in service for the evening load; the pressure of 155 pounds was being carried on the boilers, steam mains, etc.



VIEW OF BOILER ROOM, PATERSON, N. J., EDISON STATION, AFTER COLLAPSE OF COAL STORAGE BINS.

A fair idea of the damage which occurred to the steam main can be obtained by referring to the accompanying cut, which shows only part of the iron work on top of the boilers, as all of the coal and a large proportion of the framework was removed at the time photographs were taken. It will be seen that the steam main was entirely demolished, and so great was the force of the fall that part of this heavy piping was smashed in as though it had been made of paper. When the side of the coal bin fell the force was so great that when it struck the safety valves the latter pierced the one-quarter-inch plate, presenting the appearance of projectiles in the plates.

It is remarkable that the only injury sustained by the boilers consisted of bending some of the short tubes connecting the upper parts of the steam drums and making slight depressions around the steam outlet of the nozzles of the four boilers.

The general popular impression immediately at the time of the accident was that the boilers had exploded, for the reason that so great was the force and quantity of the steam which was liberated when the steam pipe connections broke, it was difficult to form an adequate conclusion as to just what had happened. The boiler house became full of steam and it was impossible for several minutes to permit even a casual examination to ascertain just what the accident was. Developments soon proved, however, that the entire battery of boilers were intact and that nothing had occurred to them except as above outlined.

No description can give even an approximate idea as to what it means to distribute 1,000 tons of coal in such a hurried manner. It was nothing short of an avalanche. The boilers were buried from the floor up to a height of at least 10 feet in the coal. Fortunately the four men who happened to be in the building at the time the accident occurred managed to escape without any injury. Much credit is due to the general manager, Mr. Brock, and the chief engineer, Mr. Merrill, in having taken such prompt and positive action in the matter of removing the coal so that within a few hours the boilers were made accessible. The natural result of having the steam pipes destroyed, of course, was the shutting down of the entire plant. Within 28 hours after the accident occurred, steam pipes were temporarily arranged so that one of the boilers could be operated, and this boiler was operated from midnight of the 16th inst. until the following morning, carrying pressure steam to about 750 i. h. p., and for the following 15 hours the same boiler supplied steam to three of the Ball & Wood engines, developing from 1,400 to 1,800 i. h. p. As the boiler has a nominal rating of 450 h. p. and the engines are compound condensing, it will be seen that the boiler was operated at least 113 per cent. above its rated capacity at the regular pressure of 150 pounds! Forced draught was utilized to produce the extreme overload. Notwithstanding the high percentage of overload, no trouble whatever was experienced on account of water being carried over with the steam, and no better test has ever been made to demonstrate the fact that the "Stirling" boilers furnish dry steam irrespective of the duty they are called upon to develop.

This performance of the boiler following immediately after the enormous strain brought upon it on account of the amount of coal and ironwork, without previously having made any water test to determine whether the boiler was injured in any manner, demonstrates the fact that the construction of the Stirling boiler is more than could be asked by the most exacting engineers. It also demonstrates the fact that all wrought steel in the construction of boilers can be relied upon under the most exasperating conditions, whereas, if any of the parts under pressure or in the supports had been of cast iron there would have been a weak element in the construction which would have a tendency to have produced the complete demolition of the boilers. Only the best of material was used in the bricking up of the boilers, and although they were entirely supported independent of the brickwork by wrought steel columns and girders, it should be remarked that the results of the accident show that first-class work pays in the end, as none of the brick walls were in any manner whatsoever injured.

ELECTRIC CARS TO THE GRAND CANYON, COLORADO.

Lombard, Goode & Co., of Chicago, are the backers of a railway from Flagstaff to Williams, Ariz., or to the crest of the Grand Canyon of the Colorado.

Just now tourists have to ride 100 miles by stage to see this wonderful and majestic sight. The company now controls several miles of right of way along the southern rim of the canyon, which will be used in the building of an electric scenic road for sightseeing purposes.

The several waterfalls will furnish 30,000 horse-power, allowing for liberal loss in transmission.

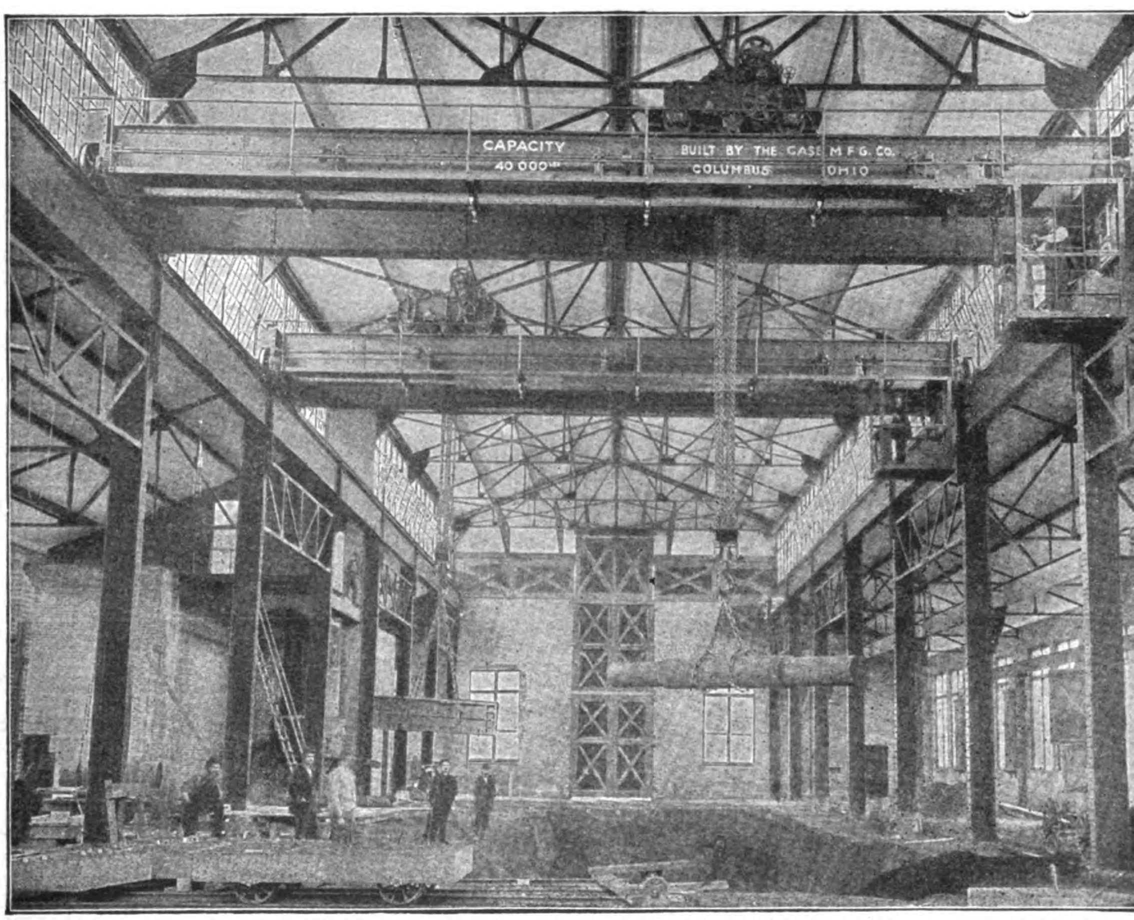
POWER TRANSMISSION

CASE THREE MOTOR ELECTRIC CRANE.

The accompanying illustration shows two modern three-motor electric cranes of 40,000 pounds capacity each, which have just been placed in operation in the C. & G. Cooper Co.'s foundry at Mt. Vernon, O. Among the special points of merit is the construction of the bridge in which the girders and end plates are riveted together securing the desired strength with great rigidity and freedom from vibration which is so destructive. The arrangement of the bridge wheels is such that they can be removed and the boxes replaced by simply raising the crane off the gudgeons, thus making all the working parts most accessible. The bridge motor is located near the operator's cage, thus exposing it to the least heat from the different departments of the foundry and so arranged that the motor as a whole or in part can be detached without disturbing any other parts of the machinery. The hoisting gear of the hoisting trolley is of the double drum type, the chain winding from each end, thus distributing the load equally on the hoisting drums and the bridge girders.

The trolleys are built with the Thompson automatic retaining hoisting gear, a newly patented device which requires no brake, to prevent the load from backing down. The lifting load provides its own braking power. Thus the ability to hold increases as the load increases, and the control is made absolute and independent of any brake or electrical current. This will be recognized as a great advantage in both efficiency and safety. The hoisting and trolley motors are so located on the trolley that either can be easily removed or detached without derangement of other parts of the machinery. The gearing is all machine cut and the bearings are either babbitted or fitted with bronze bearings. This equipment is found to be best adapted to the work which it has to do and to permit of its being renewed with but little trouble. The motors used are of the best modern design and an inspection of the cranes conveys the idea of efficiency and durability.

These cranes were built and erected by the Case Manufacturing Company, of Columbus, Ohio.



Electric Cranes—Case Manufacturing Co.

NEWS AND NOTES

DISCUSSING A PACIFIC CABLE.

A special dispatch from Vancouver, B. C., of September 7, says: The following named telegraph men held a closed meeting in Vancouver in connection with the proposed cable line from Vancouver to Australia: George G. Ward, vice-president and general manager of the Commercial Cable Company; S. S. Dickenson, superintendent of the company at Canso, where the Canadian Pacific line connects with the Atlantic cable; R. V. Dey, secretary to President John W. Mackay; J. Wilson, Pacific Coast superintendent of the Canadian Pacific telegraphs; L. W. Storrer, superintendent of the Pacific Postal Telegraph Company. After the meeting no news of a direct nature could be obtained regarding the business transacted, but statements were freely made that inside information obtained warranted the announcement that a Canadian Pacific cable from Vancouver to Australia would be an assured fact at a comparatively early date and that the present meeting had to do with some very important preliminary arrangements in which Mr. Mackay is to take a very prominent part.

Mr. Storrer stated that his company would, of course, handle the Pacific cable work at this end, and that he, with others, would inspect the proposed landing stages in British Columbia at once. The entire party will leave for Victoria to-morrow.

ENGLISH AND AMERICAN ELECTRIC RAILWAY DIVERGENCIES.

IT is most gratifying to note the increasing interest taken in electric railroading in England, made apparent by the gradual though steady addition to the number of such roads in operation. In respect to the number of electric roads, England is far behind some of its continental neighbors, though as regards date of installation its roads were well among the earliest. But now that England is waking up to its opportunities there is arising the question of its sources of supply for railway material of all kinds, and recent developments seem to foreshadow a change in the present condition of affairs. Having so rapidly and fully developed the art it was but natural that this country should be drawn on for much of the material used on English railways in the past. But that America can hardly hope for the bulk of the English electric railway trade in the future is strikingly shown by a recent example. Some years ago, when the short line connecting Leeds with Roundhay was constructed, American manufacturers supplied the engines, dynamos, motors, cars, trolley wire, switchboards, trucks and gearing—in fact, everything but the boilers and the rails. In the new Leeds tramways just opened to traffic, however, we note that the only supplies of American make are the trolley wire, trucks and part of the gearing. There is nothing surprising in this; on the contrary, it is a wonder that it took such a long time to come about. It would be strange, indeed, if English manufacturers should have confessed themselves unequal to meet the demands of a new industry, and to let outsiders carry off the trade without an effort to prevent it. It is plain, therefore, that if American manufacturers want to retain their hold, even partially, on the English market, they must keep in advance and compel trade by offering a superior article.

In line with this change of base for electric railway supplies is the recent refusal of the Liverpool Town Council to sanction the appointment of an American as consulting engineer for the proposed city electric railways. The gentleman in question, whose name need not be mentioned, has had an experience, perhaps, second to none, in electric railway construction in all its branches. One of our London contemporaries in applauding this resolve of the Liverpool authorities considers it both politic and patriotic not to encourage those beyond the English borders to a greater extent than those within. Our contemporary is willing to give us all the honor and credit due for having built up the electric traction industry, but it does not follow, it asserts, that American methods—constructional, commercial or consultative—are suitable to English requirements, and, if not, why place such touching faith in Transatlantic men and methods? It goes on to say that it is not to be supposed for one moment that English electrical and tramway engineers have during the past seven years failed to "mark, learn, and inwardly digest" all that American experience can teach them—and more to the same effect. And yet we venture to say that an experienced American electric railway engineer would be found a paying "investment" by the Liverpool or any other English municipality or company undertaking to install an extended system of electric railways. Three thousand miles is a long distance from which to "mark learn and inwardly digest" an entirely new art. American electrical journals and books and the papers contributed to American electrical societies may, no doubt, have done much to keep foreigners au courant with what we have been doing, but without desiring in the least to belittle the efforts or value of the American electrical press, we submit that what gives the engineer his greatest value is experience. If this were not so every college graduate who has the rules and formulæ of his profession at his fingers' ends would be the superior of many an engineer of twenty years' standing who has long since forgotten his calculus and the theory of functions. The point here at issue is not one of knowledge but of experience. We grant that many wideawake English engineers may have an excellent knowledge of electric railway work, as evidenced by several admirable English works on the subject, but the experience for which engineers are consulted and paid can only be gained by actual practice. If this view be correct it would certainly be advisable to consult American electric railway engineers. The differing conditions between American and English practice, which constitute the staple of our contemporary's argument, do not appear to us to be so great as to weigh at all heavily against the American engineer on English soil. Besides, we imagine, that in some respects we do things better here, and that even the conservative Britisher could be brought about to adopt some American methods—"constructional, commercial and consultative," to his advantage.

ELECTROLYTIC ACTION IN CONDENSERS.

AS condensers are likely to be used more and more in connection with alternate current work, it is of importance to recognize the action of electrolysis, which may have an appreciable influence on their performance. This is well brought out in the excellent paper read by Dr. Guthe before the A. A. A. S. at Detroit. Besides the other disturbances that this action may bring about in condensers, Dr. Guthe points out that the heating observed in condensers is due probably in large part to the Joule effect, rather than to dielectric hysteresis. The moral of this is that too much care cannot be exercised in the elimination of all moisture from condensers intended for alternate current work—a point which has already been recognized by some manufacturers.

PATENT LAW REFORMS.

IT will be generally conceded that some of the Statutes relating to patents in the United States might be amended to advantage and that some of the methods in vogue in the United States Patent Office might be changed with benefit to the patentees of the country. We doubt, however, whether the condition of affairs is such as to call for such radical changes as are suggested in a series of questions submitted to the National Association of Manufacturers. Among these questions the first relates to the advisability of the Government charging an annuity on patents, trade-marks, copyrights, etc., in order to invalidate such patents as are not considered by the owners of sufficient value to warrant the annuity, but which, nevertheless, stand a menace to new and useful patents for fear of infringement. A very large proportion of the patents in force, it is argued, are of little or no value to the owners, and are not being made use of, but are often found to contain some element making it necessary to procure their control in order to avoid possible litigation or infringement by patents of later date, the merits of which make it desirable for them to work, both for the owner and public. The cold-blooded assurance of the proposers of this scheme is worthy of admiration, but results of the change are plainly evident. The proposition as it stands amounts to nothing less than a confiscation of the rights of a patentee who may be either too poor to work his invention or who, for any other reason, may be incapable of carrying it out in practice. We do not, for a moment, doubt that some manufacturers would like to see many existing patents wiped out, but there is neither justice nor equity in such a proceeding. We are not oblivious to the fact that such an annuity system as that proposed is in vogue in most European countries, but the system has never recommended itself here, and many an American inventor has had good reason to deplore its existence. If it be a question of revenue for the Government to maintain the Patent Office, it need only be pointed out that the United States Patent Office is its only self-sustaining department, and at the present moment shows a balance to the good of nearly $5,000,000 extracted from the inventors of the country since the foundation of the patent system. The suggestion that foreign inventors should be compelled to pay an annuity in conformity with the practice in their respective native countries also seems inexpedient, and, if carried out, would probably lead to reprisals on the part of those foreign governments, to the detriment of American inventors. Recent action of this very nature following the passage of the Dingley Tariff bill ought to be a sufficient warning on this score. We are heartily in favor of the suggestion, however, of separate courts of adjudication of patents to expedite litigation, though the recent constitution of the Circuit Courts of Appeals has done much to mitigate the evils of the past. One can understand that many grangers should feel embittered toward the patent system, after having had to pay royalty on their driven wells, but why manufacturers who have been so greatly benefited by the patent system should do aught to curtail its value is beyond our comprehension. It is true that a patent constitutes, and is intended to constitute, a monopoly, but far from being one "in restraint of trade," it has in almost every instance been a stimulator and creator of trade which never existed before. The abuses which have arisen out of the patent system in the past, and we do not pretend to say that such have not existed, are due largely to inherent defects in the Statutes and Patent Office practice; these are gradually being eliminated, and in time will cease to exist. By all means, let the patent system alone; it has suffered enough from its enemies, without being still further harassed by its friends.

A USELESS STRUGGLE.

WE believe that very little opposition was encountered by the old horse railroad companies, on the part of their car drivers when electric traction was introduced, and that the men themselves hailed the change with delight as relieving them of a good deal of labor and the worry of keeping a pair of brutes up to schedule time. Reasoning by analogy, therefore, one would imagine that the cab drivers would view with similar approval the introduction of electric cabs, but, if we are to judge by recent events in London, such is not the case. In fact, at a meeting of the executive committee of the London Cab Trade Council, in which the question of electric cabs came up for discussion recently, a resolution was read expressing disapproval of the introduction of electric cabs on the streets of London, and urging all cab drivers, in the interest of the cab industry, to discourage any further development of public vehicles driven by motive power. The position in which the London Cab Trade places itself is evidently little short of ludicrous. To imagine for one moment that the tide of progress can be stemmed by any such resolution is the height of short-sighted folly. If electric, or any other automobile, cabs can be operated more cheaply, and with greater comfort to the riding public, they will be adopted, and their increasing number seems to point strongly in this direction. The horse has practically been banished from the car track, and it may not be long before it will be driven from the street entirely. The thing for London cab drivers to do is to join in the march of progress, rather than to enter into a struggle, the outcome of which can only be defeat for them.

X-RAYS AS A CURE FOR BLINDNESS.

THE subtle properties of the X-rays very soon after their discovery suggested their employment as a medium for enabling the blind to see. So far as we are aware, however, no tangible results were obtained, although numerous experimenters worked in this direction. The suggestion that the X-rays themselves might be used as a cure for blindness rather than as a medium for distinguishing objects is a remarkable one, yet if we are to believe reports, a case of this kind is recorded from Havana, where a physician claims to have partially restored the sight of a blind man by means of the application of the X-rays. Considering that the patient had previously been given up as a hopeless case, this new development may well create surprise. While we have every confidence in the good faith of the gentleman through whom the facts have reached the public, it would be the part of prudence to await more complete details before accepting the facts as fully demonstrated, and thus giving rise to hopes which may not be realized.

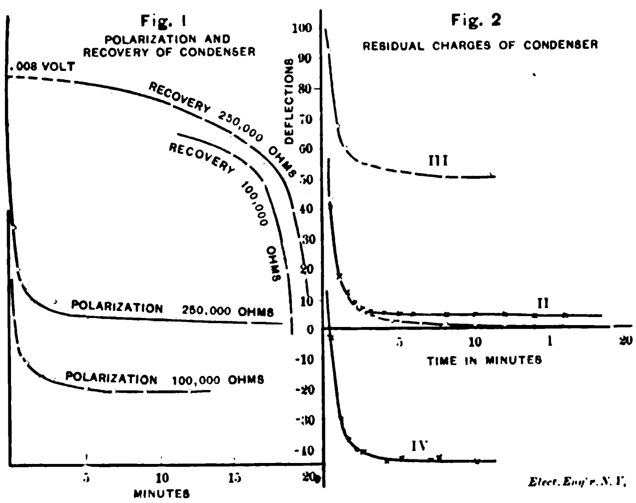
MISCELLANEOUS

ELECTROLYTIC ACTION AND INSULATION RESISTANCE OF A COMMERCIAL CONDENSER.[1]

BY DR. K. E. GUTHE, UNIV. OF MICHIGAN.

THE insulation resistance of a cable or of an absorbing condenser is a function of the time during which an external e. m. f. is applied. The apparent resistance increases very rapidly at first and then approaches slowly a maximum value. The methods usually employed for determining the insulation resistance are the direct deflection method or those in which the cable is charged, then allowed to leak, and after a given time discharged or recharged. We measure the amount of charge which goes into the condenser and base the calculation on the supposition that it also goes through the dielectric. As the absorption becomes smaller, the resistance is apparently increasing, the effect of the soaking in of the charge becomes less and less and finally only the quantity of electricity which leaks through remains. The question arises whether the large change of resistance is only due to the absorbed charge. To decide this we have to find a way for separating the two components.

Among the condensers in our laboratory we found one of a capacity of 10 microfarads, subdivided into units, which showed unmistakable signs of electrolytic action probably due to traces of acid in the paraffin used as the dielectric. The



FIGS. 1 AND 2.

condenser had previously been subjected to a voltage of 20 volts and had been afterward short circuited for several days. On opening the circuit and discharging the condenser at equal intervals through a ballistic galvanometer, we obtained appreciable deflections, which increased with the time to a maximum. After this was reached the deflection remained constant, no matter how long the time-intervals (from 15 seconds to 5 minutes) between consecutive discharges were taken. Apparently the discharge was not due to an absorbed charge leaking out, but the condenser acted like a cell which has been short circuited and recovers on the opening of the circuit.

Since under these conditions the condenser is nothing else than a high-resistance battery, we can employ for finding its resistance a method which is independent of an external e. m. f. The simplest way is to measure the e. m. f. (E_1) and the difference of potential (E') when the circuit is closed through a known external resistance R; then

$$r = \frac{E - E'}{E'} R.$$

To measure E', the cell has to be closed for a very short time only. The closing and opening of the circuit was done automatically by means of a pendulum apparatus, so that no appreciable polarization could take place.

The resistance of the condenser had been determined before by direct deflection and was found to be more than 250,000 ohms for one hour, after the external e. m. f. of 70 volts had been applied. It had become fairly constant, but was still increasing slightly.

The method outlined above gave us an entirely different result, since the resistance was found to be a great deal smaller than expected. We charged and discharged a Stanley condenser of 3 microfarads with the e. m. f. (d) and the P. D. (d') when the external resistance was R. The resistance calculated is given under r.

R	d	d'	r
12,500 ohms.	70	42	8,300 ohms.
25,000 ohms.	70	52	8,600 ohms.

If the circuit is closed only a very short time, the resistance of the condenser is only about 1-30 of the resistance found by the direct deflection method.

A number of experiments were undertaken to show the rapidity with which the condenser polarizes and recovers. The curves correspond closely to the curves taken with ordinary cells. They are quite steep at the beginning of the polarization, but show also a fair recovery. In Fig. 1 the results are plotted. Curve I. was taken with an external resistance of 250,000 ohms; Curve II. with one of 100,000 ohms.

In order to determine the residual charges in such a condenser it is apparently necessary to balance first the e. m. f. of the condenser and then apply the external potential difference. The results are plotted in Fig. 2. In Curve I. the e. m. f. was in the same direction in which the e. m. f. of the condenser would act; in II. the two are opposed to each other. Both curves coincide at first. After a short time both run parallel to the X-axis, and we found by changing the interval of time from 30 seconds to 1 and 2 minutes, that the remaining constant deflections are due to polarization in one case, in the other due to an increase of the e. m. f. of the cell, and not due to residual charge. The charge absorbed is independent of the direction of the applied e. m. f. (in our case 3.4 volts for .2 second). Curves III. and IV. show the results when no balancing cell (about .02 volt) is inserted in the circuit.

After this we tried to reverse the direction of the e. m. f. of the condenser. The combined 10 microfarads had an e. m. f. of .008 volt. We first put 3.8 volts on all 10 microfarads for 30 minutes, then on only 5 microfarads for 2 days. After that the whole condenser was short circuited for some time and then the potential differences of the subdivisions redetermined. The application for 30 minutes had not been sufficient to reverse the e. m. f., but the divisions subjected to the impressed 3.8 volts for 2 days showed the desired effect, some quite strongly. The different units showed great differences in the value of the e. m. f., and it was decided to use in the following one of the reversed units, which showed a large e. m. f. (.0305 volt) and a small resistance.

Now, we undertook to determine how the surprising difference in the resistance of the dielectric depends on the time during which the circuit is closed. Experiments made with alternating currents show in general that the resistance of a dielectric works out to be larger, the slower the rate of vibration, and indeed this variation being a great deal larger than could be expected from the theory. A striking example has been published by Eisler (Ztsch. f. Electrotechn., June 15, 1895). The resistance of a 2.5 m. f. condenser varied from 64,800 to 22,100 ohms when the frequency of vibration was varied from 17.9 to 45.1. Hand in hand with this goes the experience that the specific inductive capacity varies similarly. But Threlfall (Phys. Rev., July, 1897) showed that after continuous and careful drying the effect is greatly reduced.

The only observation of a dependence of dielectric resistance upon the time during which a constant current is flowing through it, has been made by Hertz (Wied. Ann. 20, p. 279, 1883), who investigated the conductivity of benzene. Commercial benzene showed a very large increase of resistance with the time. He showed, moreover, that what he calls the residual charge, is due to some kind of polarization, and not to absorbed electricity.

In our experiments we discharged the condenser, one microfarad, through different external resistances, and measured the throw of a ballistic galvanometer. Then we made the auxiliary e. m. f., which was found to balance the e. m. f. of the condenser, send a current during the same time through the galvanometer.

In the experiments the time was varied from a very small fraction of a second to about .2 second, which is the longest time we could safely take, without polarizing the condenser.

The general results deduced from these observations are:
1. The dielectric resistance of a condenser, in which we find

[1] Abstract of a paper read before the A. A. A. S. at Detroit, August, 1897.

electrolytic action[1], increases with the time during which a current flows through it.

2. The time being constant, the resistance seems to be the smaller, the larger the current.

It seems therefore clear that, especially with alternating currents, the greatest care has to be exercised in the selection of a propr condenser. The higher the frequency the greater will be the loss of energy due to the small resistance of the condenser. This is to be considered in addition to whatever may be lost by real absorption. I believe, moreover, that the heat produced in condensers when subjected to an alternating difference of potential is mostly due to Joule's effect and not to hysteresis.

The second point becomes clear only when the circuit is closed for a comparatively long time, the influence of the errors of observation being too large in the other cases. Polarization, if present, would make the differences less pronounced.

These results gain in importance from a theoretical point of view, if we compare them with those obtained with batteries. Uppenborn, Carhart, Greeff and others have observed a decrease of the resistance of batteries with increasing current, and this effect is more pronounced in dry batteries than in liquid cells. Apparently this variation depends to a great extent upon the solvent in which the electrolyte is contained. Moreover, I have found, pursuing the investigation on ordinary cells a little farther, that a variation of the time during which the circuit is closed, gives us different absolute values for the resistances. Greeff, as well as I, could not obtain the same results for the curves by first increasing the current and then decreasing, or vice versa. The second set always gives a curve for the resistance which lies above the first, the resistance having increased by the use of the cell. Greeff found, moreover, when he measured the resistance of cells with an alternating current, that the same form of curve resulted, but that the values of the resistances were always smaller than when he employed a steady current. This explanation, namely, the formation of acid, I was able to disprove by chemical analysis.

Corresponding experiments with electrolytic resistances seem to confirm our results. Various alternating current methods were compared with a constant current method recently proposed by Stroud and Henderson, who employ two high-resistance vessels in two arms of a Wheatstone bridge and eliminate the error due to possible difference of polarization by employing a high voltage. The values of the resistance obtained by the last method is always a little larger, about 1 per cent., than the corresponding values obtained by Kohlrausch's method. We could also verify Wien's observations that the resistance appears to be the larger the lower the frequency of the alternating current.

In most of the experiments I was assisted by Mr. G. F. Fisher, and I wish to express my obligations to him for the valuable help he has rendered me.

FLUE GAS ANALYSIS IN BOILER TESTS[2]

BY PROF. D. S. JACOBUS.

THE paper, which the author intends to publish in full in the Transactions of the American Society of Mechanical Engineers, will contain a comparison of the results obtained by means of the Elliott gas analysis apparatus for the composition of gas with the composition as determined by mixing together known volumes of the elementary gases. In addition to this, the errors involved by the absorption of the gases in the water used in the apparatus and in the solutions will be discussed.

Experiments already made have shown that a large error may arise in measuring the initial volume of the gas on account of the absorptive power of the water for carbonic acid gas. To eliminate this error, we pass a considerable volume of gas through the measuring tube, allowing it to bubble up through the water in the bottle which forms part of the apparatus. This causes the water which clings to the sides of the glass measuring tube to become saturated with gas, so that there is no absorption before recording the initial volume; whereas, if the tube is simply filled with gas without forcing an excess of gas through it, there may be a considerable amount of carbonic acid gas absorbed before the initial reading is obtained.

To obtain an average sample of the gas over any desired interval of time we use collecting bottles, as shown in Fig. 1. The bottle, A, is completely filled with water, and the bottle, B, is filled to just above the point at which the rubber tube, b b b, is connected. Gas is drawn into the bottle, A, through the tube, a a a, leading to the flue, or chimney. When gas is drawn into the bottle, A, the bottle, B, is lowered, as shown in the sketch. The rate of flow of gas into the bottle, A, is regulated by adjusting the glass cock, D. After filling A the cock, C, is closed, and the bottle, B, raised and placed on a shelf some height above A. The gas, which is then under pressure, is then led through a rubber tube connected to the cock, E, to the Elliott apparatus.

The bottle, B, is lowered about 5 feet below the bottle, A, in order to cause the amount of suction, and, consequently, the rate of flow of water from the bottle, A, to vary only between small limits. If desired, the bottle, B, can be lowered as the bottle, A, is being filled with gas, in order to obtain a more uniform flow of water from A than would exist with the bottle, B, stationary.

The flow through D varies as the square root of the head; hence, a slight difference in the head of water will not cause a great variation in the rate of flow.

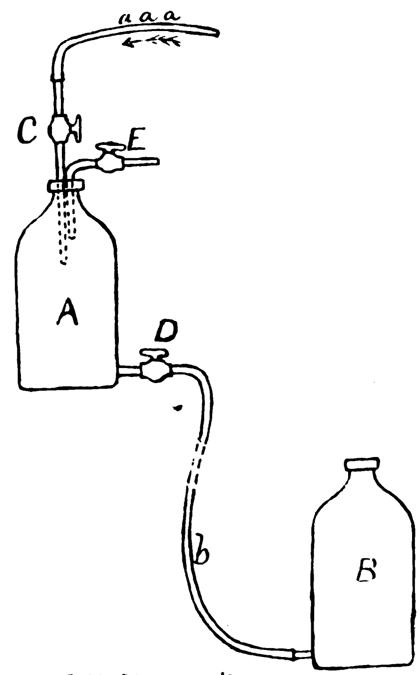


FIG. 1.

To allow for the absorption of gas in the collecting bottles, we draw the bottle, A, about one-half full of gas a number of times before starting the tests, and shake the water it contains thoroughly, so as to cause it to become saturated with the gas.

Experiments have been made by adding salt to the water to decrease the absorptive power, and it is proposed to try other liquids than water. The results of all these experiments will be given in full in the paper.

ARC SPECTRA.[1]

BY PROF. ARTHUR L. FOLEY, INDIANA UNIVERSITY.

THE image of a normal electric arc appears to consist of three regions; a central violet portion, an outer yellow sheath or flame, and an intermediate sheath of blue. By means of a Rowland grating and Brashear mounting, and a concave mirror to focus the image of the arc upon the slit, a photographic study was made of the spectra of these regions under four conditions: (1) a vertical arc and slit, (2) a vertical arc blown out by a magnet, (3) a horizontal arc and slit, (4) a horizontal arc and vertical slit. A table gives some results with a vertical arc and a vertical slit through the center of each region. The table extends from $\lambda = 3092$ to $\lambda = 5015$. The whole number of lines visible was 1,994, of which 1,842 were measured and 1,787 identified.

[1]Almost all commercial paraffin condensers, which show strong absorption, show also traces of electrolytic action. The two seem to be intimately connected. In condensers in which great care has been taken to exclude moisture and air, for instance, in the Stanley condensers, no electrolytic action can be found, but also the absorption is extremely small, as compared with the former.

[2]Abstract of a paper read before the Amer. Assoc. Adv. Sci., at Detroit.

[1]Abstract of a paper read before the A. A. A. S. at Detroit, August, 1892.

The table shows that the lines rapidly decrease in number as the slit is moved from the center of the arc to the outer edge. This is due chiefly to the fading out of the carbon bands, only a few of the stronger carbon (or cyanogen) heads being visible in the outer sheath. But the fading out is not confined to the carbon as the lines of all the other elements of the table show the same tendency, though to a much smaller degree.

The lines of the table were not only measured and identified, but their intensity was estimated at three points; at the upper end near the positive carbon, at the center, and at the lower end near the negative carbon. The calcium and iron lines were relatively much stronger in the outer regions than the lines of any other element. All the lines of any one element did not fade out at the same rate. But it does not appear that there are any lines which have a maximum of intensity in the outer sheaths. Neglecting for the present the thickening of the lines at the poles and considering each region of the arc as a whole, it may be concluded that the differences observed in the spectra are due chiefly, if not entirely, to temperature differences.

The spectra of twelve elements were studied to determine the nature of the lines near the carbons and directly between them. The spectrum was obtained by removing the core of one or both of the carbons and replacing it by the salt of the metal to be studied. The salts used were barium carbonate, sodium nitrate, the chlorides of zinc, calcium, strontium, potassium and lithium, the sulphates of chromium, cadmium and aluminum, and the oxides of rubidium and titanium.

Photographs were taken with both direct and reversed current; when the salt was in the upper carbon only, when in the lower carbon only, and when in both carbons. In every case the carbon lines clung to the positive pole and the metallic lines to the negative pole. When the upper carbon contained calcium and was made positive, all the calcium lines extended across to the lower negative pole. But when the current was reversed, of the forty-seven lines which appeared at the upper negative pole, only fourteen extended across to the lower positive carbon. The latter were due to calcium contained as an impurity in the lower carbon, for they were not stronger than in the ordinary arc.

The following experiment is more conclusive:

The negative carbon of a horizontal arc was filled with calcium chloride. A new plain carbon formed the positive pole. The carbons were placed 1 cm. apart and an arc was formed by passing between them a third carbon which served to bring the poles into momentary contact. After one minute the current was shut off and the carbon containing the calcium was replaced by a new plain carbon. The arc was then formed by means of a third carbon, and the spectrum was photographed. No calcium lines appeared except those always present in the ordinary arc.

In the second part of the experiment a plain carbon was used as a negative pole and the calcium was placed in the positive pole. The arc was formed as before and allowed to continue for one minute. The positive pole containing the calcium was then replaced by a new plain carbon, the arc was formed and the spectrum photographed. The calcium lines came out very clear and strong, almost as strong as if the negative carbon had been filled with the salt. There can be but one conclusion. In the first case the calcium was in the negative pole and there was no tendency for it to pass across to the positive pole. In the second case it was placed in the positive pole and it freely passed over to the plain negative pole. The latter became so impregnated with it that it was capable of giving a strong spectrum of calcium when it was afterward used in an arc with a plain carbon.

The electrolytic nature of the arc was further confirmed by a series of measurements of the voltage necessary to maintain an arc of given length between unlike electrodes. It was found that a higher voltage was required when the salt was placed in the negative pole than was necessaray when the salt was in the positive pole. When one of the carbons was replaced by a metal rod, a higher voltage was required when the current was flowing from the carbon to the metal than when it was flowing in the opposite direction. The details of this portion of the work will be given in a subsequent paper.

As far as could be determined, the order of the elements, as regards the tendency of their spectral lines to cling to the negative pole, is the same as their order in the electro-positive-negative series.

A study was made of the spectrum of the enclosed arc with a lamp manufactured by the Helois Electric Company. The lamp was modified so that the lower carbon, which was hollow, extended outside the globe.

When the spectrum was photographed immediately after starting the arc, it was identical with the spectrum of the open arc. After a minute or two the arc shortened and the metallic lines began to disappear, soon disappearing almost entirely. The carbon and cyanogen bands were stronger than at first.

It appears that a comparatively rapid disintegration of the carbon poles is necessary to supply enough material in the arc to bring out clearly the metallic lines which are due to very small quantities of the metals contained in the carbons as impurities. The rapidity of the disintegration depends upon the quantity of oxygen present in the globe. After the oxygen had become exhausted by allowing the arc to burn a few minutes, the wasting away of the poles was very slow indeed. When carbondioxide was introduced into the arc through the hollow lower carbon the wasting of the poles increased and the metallic lines reappeared. Air still further increased the wasting of the poles and the brilliancy of the metallic spectra. When pure oxygen was passed into the arc the poles were rapidly consumed. The metallic spectrum was very bright, likewise the carbon and cyanogen bands.

In the enclosed arc, as in the open arc, there was the same general tendency for the metallic lines to thicken at the negative pole, and the carbon lines to cling to the positive carbon.

A UNIVERSAL ALTERNATOR FOR LABORATORY PURPOSES.[1]

BY PROFESSOR HENRY S. CARHART.

THE design of the machine to be described was adopted for the following reasons: 1. Simplicity of construction by students in the engineering shops without special tools or dies. 2. Its similarity to a bi-polar dynamo so as to illustrate one, two or three-phase current generation but without a low limit to the frequency. 3. To illustrate practically the effect of combining e. m. f.'s differing in phase, in a variety of ways.

To accomplish these objects both the field and the armature were made with poles, the latter having two more than the former. The field revolves and is of the C. E. L. Brown type. The armature is made of sheet iron rings held together by bolts between cast iron plates. The spaces between the poles of the armature were milled out after the rings had been bolted together. The field is made of two identically similar steel castings, each with five poles symmetrically spaced and pointing in the same direction parallel to the axis. The field has thus ten poles, alternating in sign, and the armature twelve. The following are some of the dimensions:

Diameter of armature pole faces	10.25 in.
Length of faces parallel to shaft	1.5 in.
Width of pole faces	1.5 in.
Pitch of poles on armature	2.68 in.
Depth of poles	0.5 in.
Net cross section of pole in sq. in.	5.4 in.

The armature poles were wound with forty turns of No. 16 wire. The double air gap is 0.25 in. The field coil contains 1,012 turns of No. 16 double cotton covered wire.

The armature coils were wound in reverse order from pole to pole in the usual way. They are connected in pairs and the terminals of each pair are brought up to binding posts on a board on top of the machine.

Diametrically opposite poles of the field are of opposite sign, while the corresponding coils of the armature are similarly wound. Hence with a closed coil armature, the e. m. f.'s balance exactly as with a bi-polar dynamo. If therefore connection be made with the armature at two opposite points, the current in the external connecting circuit will be alternating. Further, two such circuits connected at right angles will convey currents in quadrature. By connecting at points 120 degrees apart, three-phase currents will be obtained.

Again the coils may be joined either in mesh or star fashion by means of the binding posts, and we may zig-zag across either with two or three-phase connections, so as to connect opposite coils by twos or threes with no phase difference between the two opposite groups. This connection of course gives the highest e. m. f.

It is evident that the phase difference from coil to coil is 30 degrees, or one-twelfth of a period. Hence the voltage for a given magnetic flux cut per second, calculated in the usual way, must be first multiplied by two to reduce from maximum to virtual volts, and then the equal e. m. f.'s generated by the several coils must be added geometrically with a phase difference of 30 degrees from coil to coil. Since the e. m. f.'s of the several coils are equal and differ in phase by a twelfth of a period, the series may be represented by a regular polygon of twelve sides. Hence if E be the e. m. f. of one coil, the following will be the e. m. f.'s of the several groups of coils:

E. m. f. of two coils, $2\ E \cos 15^\circ = 1.93\ E$.

E. m. f. of three coils, $E + 2\ E \cos 30^\circ = 2.73\ E$.

[1] Read before the American Assoc. for the Adv. of Science, Detroit.

E. m. f. of four coils, 2 E (cos 15° + cos 45°) = 3.346 E.

E. m. f. of five coils, E + 2 E (cos 60° † cos 30°) = 3.73 E.

E. m. f. of six coils, 4 E cos 15° = 3.86 E.

It will be seen that the phase difference between the coils reduces the e. m. f. of the six in series on either side to 3.86-6, or 0.643 of what it would be were there no such phase difference.

It will be seen from the subjoined table that the observed e. m. f.'s agree every closely with those computed from the foregoing equations.

	Observed.	Computed.
One coil	21	20.5
Two coils	40.3	39.6
Three coils	55.5	56
Four coils	69	68.6
Five coils	75.5	76.5
Six coils	77.5	79.1

With about 2,000 ampere turns on the field coil, the following observed voltages were obtained for the several connections described in the first column. The computed values are readily obtained from the preceding expressions:

Connection.	Observed.	Computed.
Two-phase mesh	79	79
Two-phase star	112	112
Three-phase mesh	69	68.6
Three-phase star	121	118.8
Three-phase zig-zag	136	136.8

The alternator was driven by a motor on a power circuit in which the voltage varied a good deal. Some of the irregularities of voltage in the generator are accounted for by the variation in speed of the motor.

SOME TESTS ON THE VARIATION OF THE CONSTANTS OF ELECTRICITY SUPPLY METERS, WITH TEMPERATURE AND WITH CURRENT.[1]

BY G. W. DONALD RICKS, A. C. G. I., A. I. E. E.

THE general object of the tests was to afford a means of studying the behavior of direct current electricity supply meters with regard to variations in the accuracy of their indications under varying conditions of temperature, current and potential difference.

Some of the more important meters were put through a series of tests which aimed at ascertaining, 1. How the accuracy of the meter depended upon the current at various constant temperatures, all other conditions being maintained constant. 2. How its accuracy depended on the potential difference at constant current and temperature.

The first of these tests was carried out at three different temperatures—namely, about 2° C., 18° C. and 40° C., which may be fairly taken as the extreme and mean ordinary working temperatures. From the results of this test the effect of change of temperature at constant potential difference and current was ascertained. The second test is, of course, only applicable to energy meters. It was made at the maximum current and at atmospheric temperature, the pressure being varied from about 10 per cent. below to 10 per cent. above the normal value.

The tests were carried out at the City and Guilds Central Technical College upon each of the following meters, obtained direct from the makers, and not opened or in any way altered before testing: Elihu Thomson, Schuckert, Ferranti, Perry, Chamberlain and Hookham.

These, it will be seen, fairly represent the principal types of direct current meters now in general use in England.

A very fair idea of the relative advantages and disadvantages of each meter may be obtained from the accompanying table I:

TABLE I.

Meter.	Max. current in amperes.	Normal pressure in volts.	Resistance in ohms. Main circuit. At 1 ampere.	Resistance in ohms. Main circuit. At max. current	Resistance in ohms. Shunt circuit.	Power wasted at max. current. Main circuit.	Power wasted at max. current. Shunt circ't.	Power wasted at max. current. Total watts.	Fall of potential in series circuit at max. current.	Starting current per cent. of max.	Temperature coefficient.
Elihu Thomson	10	100	0.0948	0.0958	3101	9.58	3 22	12.8	0.958	1.4	−0.32
Schuckert	15	110	0.0420	0.0438	2535	9.9	4.77	14.67	0.66	1 93	−0.13
Ferranti	25	...	0.0154	0.0131	....	8.19	....	8.19	0.327	0.8	+0.07
Perry	20	...	0.00327	0.00331	....	1.32	....	1.32	0.066	1.25	−0.47
Chamberlain & Hookham	25	...	0.0137	0.0157	....	9.8	....	9.8	0.392	0.8	−0.22

The first two columns simply show the current, and in the case of energy meters the pressure for which each meter is intended. The resistance of the main circuit given in the next two columns was measured by means of a standard ammeter and a standard reflecting voltmeter, and the resistance of the shunt circuits on a Wheatstone bridge.

Considering first the Elihu Thomson meter, it will be noticed that its resistance is comparatively large, the fall of potential at 10 amperes amounting to nearly 0.96 volt. The temperature coefficient is also comparatively large, and the starting current 1.4 per cent. of the maximum current, which is, perhaps, not excessive for this class of meter, especially when used on alternate current circuits.[1]

The Schuckert has an advantage over the Thomson meter in that its resistance is very much less, reducing the fall of pressure and wasted power, but on the other hand its starting current is higher, being 1.93 per cent. of the maximum. Its temperature coefficient is also much less than that of the Thomson meter.

Turning now to the ampere hour meters, the first point to be noticed is that their resistances are very much lower than is the case with the energy meters. Not only do they save the three or four watts absorbed in the pressure circuit, but the watts wasted in the main circuit appear to be much less.

The Ferranti meter starts with a very small current, 0.8 per cent. of the maximum, and has an extremely low temperature coefficient.

The Chamberlain and Hookham meter has an equally low starting current and a moderate temperature coefficient, its resistance being rather higher than that of the Ferranti for the same maximum current.

The Perry meter has an extremely small resistance, causing a fall of pressure of less than a tenth of a volt at maximum current and absorbing only 1.32 watts. In this respect it is far in advance of all the others, but it has the disadvantages of comparatively high starting current and temperature coefficient.

PERSONAL

A SERIOUS ACCIDENT TO MR. J. H. VAIL.

On Tuesday, Sept. 7, Mr. J. H. Vail, Engineer in Chief of the Pennsylvania Heat, Light and Power Co., Philadelphia, met with an accident nearly resulting fatally. Mr. Vail was riding his wheel and came into collision with a heavily loaded ice wagon at the intersection of School Lane and Greene street, Germantown. The team was being driven on Greene street by a boy, with every indication of going straight ahead. Mr. Vail was coming down School Lane and about to turn into Greene street, when the boy driver suddenly swerved his team directly upon Mr. Vail, cutting off all opportunity for him to turn either to the right or left. While he was trying to dismount the team came immediately upon him, the pole knocking him down, the team passed over him. It did not strike him, but one of the heavy wheels passed over Mr. Vail's back and right shoulder, and only by rare presence of mind Mr. Vail jerked his head to the left side, thus saving his life. The extent of the injuries are a broken shoulder blade and several severe contusions on the back and right arm.

MR. R. W. POPE contributes to the "Railroad Gazette" an interesting letter relative to Alaska and the gold regions, based on the observations of himself and his late brother, the editor of this journal, Mr. F. L. Pope, both gentlemen having been connected with the Western Union-Pacific Telegraph line survey thirty years ago.

THE LATE HARVEY LUFKIN.—A number of the friends of the late Harvey L. Lufkin are raising a fund for the benefit of his widow, who is in destitute circumstances. A good sum has already been raised, but more will be very welcome. Contributions may be sent to Mr. J. W. Godfrey, 15 Cortlandt street.

MR. J. J. ASTOR'S smaller electric launch was run down in the Hudson River, off New York City, last week by the fast steamer "Mary Powell," and sank at once, the man in charge being saved. Mr. Astor had just landed and proposes to bring an action for damages.

BROOKLYN BRIDGE, N. Y.—The trolley cars are to cross the Brooklyn Bridge, from Brooklyn to New York and back, paying the Bridge five cents for each round trip of a car. They are to use their own motive power and build their own tracks and wires. It is a ten-year contract.

[1]Read before the British Assoc. at Toronto.

INVENTORS' RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPTEMBER 7, 1897.

Alarms and Signals:—

SIGNAL BOX. A. C. Robbins, San Francisco, Cal., 589,617. Filed March 26, 1897.
Consists of a device for automatically cutting the mechanism of the box out of the main circuit when not in use.

ELECTRIC SWITCH AND CUT-OUT FOR TELEPHONE BOXES. A. C. Robbins, San Francisco, Cal., 589,618. Filed March 26, 1897.
Means whereby the opening and closing of the door actuates the mechanism for cutting the telephonic apparatus and local battery in or out of circuit.

TELEPHONE TRANSMITTER FOR SIGNAL BOXES. A. C. Robbins, San Francisco, Cal., 589,619. Filed March 26, 1897.
Comprises a box having an outwardly opening door, a transmitter hinged therein, and a lug adapted to contact with and raise the outer end of the transmitter by the closing of the door.

ELECTRIC SAFETY APPLIANCE FOR RAILROADS. E. L. Orcutt, Somerville, Mass., 589,669. Filed Feb. 6, 1897.
An electric current is sent as a pilot from the engine into the section of the track into which it is about to enter, causing a communication to be given to the engineer whether the section ahead is safe.

DEVICE FOR INDICATING ESCAPE OF GAS. M. O'Donovan, Boston, Mass., 589,745. Filed May 24, 1895.
Employs a thermostat placed in proximity to the flame, a collar for supporting it, and adjustable screw normally in contact with the end of the thermostat and mounted on the collar.

ELECTRIC SIGNALING APPARATUS AND CIRCUIT. E. H. Owen, C. N. Williams and F. H. Donaldson, Garvanza, Cal., 589,746. Filed April 22, 1897.
A hotel call bell system.

ANNUNCIATOR SYSTEM. E. H. Owen, C. N. Williams and F. H. Donaldson, Garvanza, Cal., 589,747. Filed June 18, 1897.
Details of construction.

WATCHMAN'S ELECTRIC TIME-RECORDER. C. H. Phinney, Boston, Mass., 589,510. Filed Dec. 9, 1895.
An arrangement whereby, with any door or window open, the watchman is prevented from sending in the proper signal.

Conductors, Conduits and Insulators:—

ELECTRICAL JUNCTION BOX. G. Tailleur, Chicago, Ill., 589,760. Filed June 7, 1897.
Embodies pole bars for the conductor terminals provided with sockets to receive shunt-circuit plugs.

Distribution:—

MULTIPLE SERIES SYSTEM OF ELECTRICAL DISTRIBUTION. C. D. Haskins, Brooklyn, N. Y., 589,429. Filed June 8, 1896.
Adapted for use in connection with a system which does not employ a divided source of energy.

SYSTEM OF ELECTRICAL DISTRIBUTION. C. D. Haskins, Brooklyn, N. Y., 589,430. Filed July 6, 1896.
Automatic potential equalizer for multiple series systems.

TRANSMISSION OF ENERGY BY ALTERNATING CURRENTS. C. S. Bradley, Avon, N. Y., 589,556. Filed March 21, 1896.
Employs a generator having a definite rate, and a circuit containing a plurality of inductances in multiple arc, the inductances being proportioned to render the line resonant with periodic electromotive force.

Dynamos and Motors:—

ALTERNATING CURRENT GENERATOR. F. H. Sleeper, St. Johnsbury, Vt., 589,674. Filed May 21, 1896.
Of the inductor type.

BRUSH HOLDER. H. G. Reist, Schenectady, N. Y., 589,794. Filed May 24, 1897.
Comprises a box in which the brushes are mounted, an equalizer extending between the brushes, and a spring for applying pressure to the brushes.

Electro-Metallurgy:—

PROCESS OF AND APPARATUS FOR ELECTROLYZING FUSED SALTS. J. Boelsterli, Neuhausen, Switzerland, 589,523. Filed Oct. 27, 1896.
Consists in electrolyzing a fused alkali-metal salt and liberating the alkali metal exclusively at the surface of the electrolyte.

COMPOSITION OF MATTER FOR MANUFACTURING CALCIUM CARBID. S. Blum, Galveston, Tex., 589,592. Filed Feb. 3, 1897.
Composed of air-slaked lime, carbon, plumbago containing iron and potash.

PROCESS OF MANUFACTURING WHITE LEAD. H. C. Wolterеck, New York, 589,801. Filed April 9, 1897.
Employs electrolysis. Details of process.

Measurements:—

ELECTRIC METER. C. C. Schumacher and A. G. Zamel, Chicago, Ill., 589,672. Filed May 22, 1897.
Comprises a recorder provided with a balance wheel, a pinion of the balance wheel, a tooth segment engaging the pinion, an armature connected with the segment, and a magnet for attracting the armature.

Miscellaneous:—

SILICON ALLOY. G. De Chalmot, Leaksville, N. C., 589,415. Filed May 14, 1896.
Consists of an alloy of silicon with a metallic silicide.

ELECTRIC HAIR SINGER. D. Seide, Hartford, Conn., 589,445. Filed April 15, 1897.
Details of construction.

LIGHTNING ROD. E. Marshall Garnett, Kan., 589,566. Filed June 1, 1897.
Comprises an endless cable, a pair of cables connecting with the same and grounded at their lower ends, and provided at their upper ends with a plurality of points.

STATIC MACHINE. C. H. Myers and H. C. Rose, South Bend, Ind., 589,742. Filed Dec. 5, 1896.
Comprises a case enclosing the machine and a tank in the case containing a refrigerant.

ELECTRICAL IGNITER FOR GAS NGINES. Edward F. Moffitt, San Francisco, Cal. 589,509.AS ENGINES. Edward F. Moffit, Details of construction.

ELECTRO-PNEUMATIC MUSICAL INSTRUMENT. Robert W. Pain, New York, N. Y. 589,535. Filed May 13, 1896.
Details of construction.

Railways and Appliances:—

AUXILIARY ELECTRIC CONTACT. W. M. Brown, Johnstown, Pa., 589,412. Filed Feb. 23, 1897.
Embodies a metallic knife edge which can be powerfully pressed against the track rails.

TRAVELING CONTACT FOR ELECTRIC RAILWAYS. W. F. Weiss, Stockton, N. J., 589,452. Filed April 24, 1897.
The trolley wheel is carried on a transverse rod adapted to give it lateral play.

ELECTRIC RAIL BOND. G. H. Scott, Worcester, Mass., 589,485. Filed Jan. 26, 1897.
A rail bond rectangular in cross-section adapted to be fastened in place by means of bushings.

ELECTRIC MOTOR CAR. H. P. Brown, New York, 589,543. Filed March 11, 1893.
Employs an armature which will start without load.

UNDERRUNING TROLLEY FOR ELECTRIC RAILWAYS. S. H. Short, Cleveland, Ohio, 589,624. Filed July 29, 1896.
Embodies an elongated contact roller.

TROLLEY. F. W. Canales, Portland, Me., 589,693. Filed May 21, 1895.
A construction permitting the wheel to turn in a plane at right angles to the plane of its rotation.

TROLLEY WHEEL FOR ELECTRIC CARS. J. A. Crawford and T. E. Crow, Dallas, Tex., 589,702. Filed Sept. 12, 1896.
Comprises a frame, a wheel, a wheel axle, discs eccentrically journaled upon the axle, lugs upon the discs, and projections upon the frame lying in the path of the lugs.

DASH ELECTRIC HEADLIGHT. J. Kirby, Jr., Dayton, Ohio, 589,783. Filed Feb. 10, 1897.
Embodies a frame fastening in the dash board in which the casing is removably attached.

SURFACE CONTACT ELECTRIC RAILWAY. L. H. Parker, Schenectady, N. Y., 589,785. Filed Nov. 18, 1896.
The closing and opening of the surface contact is accomplished by means of an electromagnetic device carried by the moving vehicle.

CLOSED CONDUIT ELECTRIC RAILWAY SYSTEM. W. B. Potter, Schenectady, N. Y., 589,786. Filed Oct. 6, 1896.
A sectional conduit system employing electromagnetic contact devices.

CLOSED CONDUIT ELECTRIC RAILWAY. W. B. Potter, Schenectady, N. Y., 589,787. Filed Nov. 18, 1896.
Similar to above.

CLOSED CONDUIT ELECTRIC RAILWAY SYSTEM. W. B. Potter, Schenectady, N. Y., 589,788. Filed Nov. 28, 1896.
Similar to above.

CLOSED CONDUIT ELECTRIC RAILWAY. W. B. Potter, Schenectady, N. Y., 589,789. Filed Nov. 28, 1896.
Similar to above.

CLOSED CONDUIT ELECTRIC RAILWAY. W. B. Potter, Schenectady, N. Y., 589,790. Filed Jan. 2, 1897.
Similar to above.

SURFACE CONTACT RAILWAY SYSTEM. W. B. Potter, Schenectady, N. Y., 589,791. Filed Jan. 25, 1897.
A surface contact system, provided with a car having a storage battery and contact shoes, means for turning the car and means for reversing the connection of the storage battery to the contact shoes.

CLOSED CONDUIT ELECTRIC RAILWAY. W. B. Potter, Schenectady, N. Y., 589,792. Filed Nov. 18, 1896.
A safety device by which any leakage current will serve to open a switch which may by accident have remained closed.

Switches, Cut-Outs, Etc.

STARTING BOX FOR ELECTRIC MOTORS. R. B. Hirst, deceased, E. Hirst, administratrix, Brooklyn, N. Y., 589,433. Filed July 3, 1897.
Designed to obviate the necessity of an external switch for breaking the main circuit in order to stop the motor.

LIGHTNING ARRESTER. C. S. Bradley, Avon, N. Y., 589,557. Filed May 28, 1895.
Consists of an inductive device comprising two conductors connected with the outgoing and return wires of a circuit so as to oppose one another in inductive effect, under current from the generator, but assist one another with grounded currents, and a branch connection to earth, including a spark-gap on the line side of the inductive device.

ELECTRIC SWITCH. J. B. Smith, A. W. Ferrin and A. L. Clough, Manchester, N. H., 589,582. Filed Aug. 15, 1896.
Automatic cut-out switch for motors.

Telephones:—

TELEPHONIC MEASURED SERVICE SYSTEM. H. V. Hayes, Cambridge, and T. C. Wales, Jr., Newton, Mass., 589,431. Filed June 23, 1897.
Means for separately recording party-line calls at the central station.

MULTIPLE CUT-OUT FOR TELEPHONE SYSTEMS. A. B. Strowger and A. E. Keith, Chicago, Ill., 589,798. Filed Feb. 19, 1896.
Means whereby two line wires may serve to connect a plurality of telephone sets with the central exchange, and means whereby only one operator may connect at a time.

MR. E. TREMLETT CARTER, a well known English electrical engineer, recently inspected the electrical equipment of the B. & O., at Baltimore, as the London Underground Railway has adopted the style of motors that the B. & O. uses in the Baltimore tunnel. At the conclusion of his inspection, Mr. Carter said that it was the most complete and economically handled plant he had ever seen, and that he had never been in a tunnel that was so absolutely free from smoke.

SOCIETY & CLUB NOTES

EIGHTEENTH CONVENTION OF THE ASSOCIATION OF EDISON ILLUMINATING COMPANIES.

TUESDAY MORNING.

THE Edison Association began a very successful and unusually well attended convention at the Cataract House, Niagara Falls, on Sept. 14. The proceedings were opened by President Insull, who delivered the following address:

The decision of the members of the Association at the last annual meeting to hold its eighteenth convention at Niagara Falls was naturally dictated by the world-wide interest in the work of generating and distributing electrical energy, using the famous Niagara River as a prime motor. In assembling at a spot where so much can be learned by those engaged in electrical business, we are, as an Association, paying the highest tribute that we can to the wonderful work of those who have had the courage as capitalists and engineers to design and build a plant which has given a great impetus to the economical production of electric current, not only by means of water as the prime motor, but by all other methods for the production of electrical energy. We cannot all have the advantage of a large water power to assist in the economical production of our product right at our threshold, but in studying the methods employed here at Niagara Falls there is much information that we can take away with us which will lead us to concentrate our works at the most economical point of production in the various cities in which we live, and we can take advantage of the methods of distribution here employed to distribute our current to distant points where we desire to use it, far more economically than we can produce it at those distant points themselves. The question is often asked by those engaged in the electric light and power business why the companies known as "Edison Illuminating Companies" or "Edison Licensees" should find it necessary to combine themselves into an association. This question is best answered by the fact that the Edison Illuminating Companies all operate under practically the same form of contract with the company that controls the Edison patents, namely, the Edison Electric Light Company. In the main they purchase their goods under contract, from the same licensed manufacturer of the patent owning company, namely, the General Electric Company, and as there is but one Edison Company in each particular city, the interests of these various companies are naturally mutual. When I remind you that the various companies which we, either as officers or employees, have the honor of representing here, have invested in their business more than $105,000,000, it will be readily appreciated that it must be greatly to the advantage of the various properties which we operate that we should meet from time to time to exchange ideas as to the proper conduct of our business, and that we should continue an organization to watch over our interests in our dealings with the patent owning and manufacturing side of the Edison business.

At what happily would appear to be the close of an unparalled period of industrial depression the various Edison Illuminating Companies have certainly cause for mutual congratulation. Notwithstanding this long period of paralysis of industrial enterprise, they have, with hardly any exception, been able to show good earning capacity and to pay to the holders of their securities a substantial return on their investment. This is partly owing to the inherent merit of our business, partly to the wise foresight of the illustrious inventor whose system this business is based on, and partly to the conservatism of the original projectors of the Edison lighting and power business, who insisted that the Edison Illuminating Companies should be established on a sound financial basis.

This experience during the depressed times will necessarily lead investors to the conclusion that the securities of the Edison Illuminating Companies are amongst the most desirable of local investments, as if it is possible to earn substantial returns on capital invested during such periods of business disturbances as that which we have recently gone through, surely we can look forward to laying up a substantial surplus to provide against a "rainy day" during times of prosperity which all of us hope and some of us think we are now entering upon.

The use of large generating units in the large stations for the production of electrical energy inaugurated but a few years ago and the necessity of extending the field of our operations into distant portions of our territory has forced upon many of us the desirability of employing more economical methods of transmission with a view to the abandonment of small and expensive stations and the concentration of our production of current at the point of greatest economy. This matter was touched upon to a certain extent during the last convention. A number of our companies are now spending large sums of money on these lines, and as a result of the importance that this subject has assumed, it is but natural that a considerable portion of our time will be occupied in deliberating on this subject.

In connection with the matter of economical transmission the subject of economical storage is naturally of importance, and we should, in the course of our proceedings, be able to obtain considerable information on the advantages of the use of the storage battery in connection with the Edison system from those who have had the courage of their opinions and have invested largely in storage battery plants. I think we all concede the advantage to be obtained from the use of the storage battery from the storage point of view only, but some of us are still in doubt as to our ability to save sufficient money from their use to justify the large investment in capital they call for.

A subject of prime importance with the economical production of our product is the basis upon which we shall sell it to our customers. It should be remembered that we are engaged in a public business, and that our companies have duties to perform to the public as well as money to earn for our security holders. In fulfilling our obligations to the public the question of the basis of charging for our product is the all important one. This is a matter which on previous occasions has received our earnest attention, and is one on which there will undoubtedly be earnest discussion on this occasion.

For several years past some of the larger Illuminating Companies, members of this Association, notably those of Boston, New York and Chicago, have been in the habit of comparing the details of cost and selling price of their product, their accounts being kept on the same basis, as near as local conditions permit. The information obtained, so far as my experience goes, has been of great advantage in enabling the companies in question to reduce their cost and in assisting them to an intelligent decision as to the policy to adopt toward their customers. It seems to me that it would be advantageous to the members of this Association if a uniform system of accounts were adopted and arrangements made to compare the results obtained by the various companies operating under similar conditions. In putting such a scheme into operation a number of difficulties would naturally have to be overcome, such as the differences in local conditions and the necessity of carefully guarding information of so confidential a character, but I would suggest the desirability of the Association instructing the executive committee to take this matter up, with a view of formulating a plan which might be tried experimentally.

The changes that have taken place from time to time since the formation of this Association have rendered it desirable that some modifications should be made in your by-laws. A report will be made to you during our meeting, setting forth the changes suggested, which have been discussed and approved by the executive committee of your Association.

The main business of your executive committee during the past year has been the negotiating with the General Electric Company of a contract and specifications with relation to the incandescent lamps used by the Edison licensees who are members of this Association. As a result a lamp testing bureau has been established at the lamp factory at Harrison, N. J., which bureau is under the control of this Association and is operated for its account by Mr. Wilson S. Howell. A number of our members have taken advantage of the arrangement made, and we believe that considerable benefit will accrue to those who arrange to purchase their lamps under the contract in question. Great credit is due to the chairman and members of the executive committee for the results they have been able to achieve, and they are certainly deserving of our thanks for the time and money they have spent in this matter for our benefit. I think for the first time in the history of the electric lighting business we are now able to obtain lamps made according to specifications agreed upon, and the result must be an improvement in our service and a saving of money to our central station companies. The details as to this matter will be carefully dealt with in reports by Mr. C. L. Edgar, chairman of the executive committee, and Mr. Wilson S. Howell, the testing officer in charge of the bureau at Harrison.

The relations of the Edison licensees with the Edison Electric Light Company and its licensed manufacturers, the General Electric Company, have, during the past year, been of the pleasantest character. This is probably owing to the fact that those operating the General Electric Company since the consolidation of the Thomson-Houston Company and the

Edison General Electric Company have had fuller opportunity, as time has gone on, to appreciate the importance of the Edison licensee business to the patent owning and manufacturing interests.

The matter of patents continue to be in far from a satisfactory condition, the licensees receiving very little protection in the enjoyment of the exclusive privileges under the Edison patents, which they have every reason to look for in view of the large amount of royalty paid by them to the parent company. It is doubtful whether the Edison Electric Light Company or the General Electric Company can be held responsible for this state of affairs, as they have continued to spend very large sums of money in the prosecution of their patent rights in the courts.

It is to be regretted that many of the electrical manufacturing companies continue to foster opposition central station plants in territory already covered by good paying illuminating properties with the result of seriously affecting the credit of the customers upon whom the manufacturers must rely for trade, if they desire to create a permanent manufacturing business. We have all of us suffered more or less from this policy of the manufacturing interests, and while in some cases there may possibly be a temporary advantage to one or another manufacturer, it is natural for us to wonder what permanent advantage can come to the manufacturing interests as a whole by the adoption of methods which would seem to have in view the ultimate destruction of the goose that lays the golden egg.

With the many changes that must of necessity take place in so new a business as the electric light and power industry, the question is often raised as to whether or not our plant is of a permanent character. A close examination of the Edison system must bring home to any one the fact that the wonderful inventive and engineering talent displayed by Mr. Edison in his early work has given us the advantage of a system that is of the utmost permanency. Our main investment, in the larger cities at least, is in our underground work, and if you will look over the records of the various companies using the Edison system, I think you will find that their underground work is as useful to them now as when it was laid, and it seems to me that there is no reason for us to fear that this condition will change in the future. We may have different methods of illumination; we may get a higher voltage lamp; we may find that the current of the future will not require as large a cross section of copper as in the past, but I doubt if you will find that any method of distribution will be invented that will supplant that which we are using; and if such be the case, we should rather welcome than fear new inventions, feeling that in our own particular cities we are the most desirable purchasers of any inventions which may lessen the cost of electrical energy to our customers. When those of us who have been connected with this great industry from its early childhood recall the fact that scientists and inventors on both sides of the Atlantic persistently condemned the scheme originally laid out by Mr. Edison, we must, as central station managers of to-day, feel that we owe a deep debt of gratitude to him for his courage in insisting that the only practicable method of distribution of electrical energy was by the use of a constant pressure and a varying current when everybody else was talking a constant current and a varying pressure. This is no occasion for invidious comparisons, but with every desire to pay the highest tribute to the many brilliant men who have contributed to the success of the business of manufacturing and distributing electrical energy, we venture to claim that their work is all subordinate to the master mind who persisted in the early experimental days at Menlo Park in working on a multiple arc system, without which (with the exception of the series arc light) no form of electric light or electric energy could be commercially operated to-day.

MR. R. R. BOWKER felicitated the president on his address and the Association on the fact that the National Electric Light Association had also chosen Mr. Insull for its President this year, thus showing the essential harmony that existed throughout the art. A vote of thanks to Mr. Insull was adopted.

MR. L. A. FERGUSON, of the Chicago Edison Co., read a paper on "Economy in Distribution of Electrical Energy," in which he reviewed ably the state of the art, and expressed an opinion as to its future. He thought the day had passed for several sectional stations in a city and believed in one main station for making the current. Reviewing the possible methods, he said that the advantageous system was one embodying machines built to deliver both three-phase alternating and direct current at the same time, thus meeting the needs of transmission and the local three-wire requirements. He found rotary transformers very useful in such sub-stations fed by these generators. The other two methods, which he regarded with less favor, were those of using large three-phasers with sub-station transformers, etc., or of converting direct current in the main station into three-phase for the transmission to the sub-stations.

In closing his paper Mr. Ferguson noted that storage batteries might be used as auxiliaries, but would not increase the efficiency of the system. He held that the real field for the storage battery was in employment at the main station as an auxiliary in case of emergency and at the centre of distribution or sub-stations for the same purpose. He gave figures from current practice showing the comparative cost of a steam sub-station as against the rotary transformer sub-station.

MR. R. R. BOWKER said that his recent inquiries in Europe showed results confirming generally the position taken by Mr. Ferguson, but he pointed out that the investment already made in steam sub-stations was by no means rendered useless by the new method, as, so long as the lighting load was characterized by a high peak, the steam stations could be profitably operated to carry the peak portion of the load.

MR. H. F. PARSHALL, of London, discussed the English distribution systems for power and light, noting the high periodicity chosen in most of the English alternating distributions and the large proportion which incandescent lighting formed of the total load in these systems. He did not see an advantage for lighting alone of changing the alternating current to direct current for distribution to consumer.

MR. C. S. EDGAR pointed out that the choice of either of the three generating arrangements described by Mr. Ferguson for any given case would depend upon the proportion of alternating current and direct current in the total demand of the consumers, so that the different choice of method in Chicago and in Brooklyn had been controlled by local conditions.

MR. W. S. BARSTOW described very fully the new Brooklyn generating station at Bay Ridge, the three-phased transmission at high pressure of alternating current and the transformation of the three-phase current by means of rotaries and by synchronous motors driving arc dynamos into low tension direct current for distribution on the Edison three wire system and high tension direct current for series arc lighting. The distance to one sub-station by the route now used is twelve miles, and the service is perfect. A storage battery is placed in one station as a reserve.

MR. S. DANA GREENE pointed out in reply to Mr. Parshall that American city conditions differ from those of London and other English cities in there being an important demand for direct current for many services for which alternating current was not available. He discussed and described some details of rotary sub-stations, particularly the independent regulation of pressure at each station according to its own requirements.

MR. J. W. LIEB emphasized the necessity for the distribution of direct current by instances from both European and American practices. He incidentally noted the superiority of direct current arcs over alternating arcs; and he described a temporary transmission used by the New York Edison Company in which a two-phase motor supplied by high tension currents drove a pair of low tension direct current dynamos feeding into the Edison three wire mains at a place where there was a large demand for current.

PRESIDENT INSULL stated that the Chicago Edison Company's experience had proved the advantage of concentration of generating plant. He remarked that the instances of sub-station distribution which had been mentioned in the discussion were all located in large cities, but that the principle was equally applicable to smaller stations and that many of these might with advantage be rearranged or extended in this way. He recommended the study of the method to all present, with a view to its possible application in their own cities.

MR. BOWKER summed up the discussion by saying that no distribution would fit the conditions of central station work to-day, unless it possessed the flexibility and the wide range of application which characterized the original three wire system, and that it seemed to be impossible to secure these in conjunction with long distance transmission except by the use of rotaries; and Mr. Ferguson, in closing, adopted Mr. Bowker's expressions.

TUESDAY EVENING.

MR. GEORGE R. STETSON read a paper describing and illustrating the use of the photometer in the gas industry; the unit of measurement being the English standard candle and the photometer being of the Bunsen type.

MR. J. W. LIEB, JR., in the discussion referred to the Lummer-Brodhun photometer and the Hefner von Alteneck standard of light, with incandescent lights as secondary standards; and compared certain details of these devices. He also called attention of the members to the arrangements which had been made for the supply of calibrated incandescent lamps of sixteen candle power for practical use as station standards.

MR. S. DANA GREENE noted the difference among authorities as to classification of incandescent lamps; some classifying lamps by means of spherical candle power and others adhering to the customary classification by mean horizontal candle power, which subject was further discussed by Mr. John Howell and Mr. R. R. Bowker.

MR. CARYL D. HASKINS presented an illustrated paper describing "Recent Developments in Electrical Measuring Devices," the devices being a prepayment watt meter; improved station watt meters and tell tale dials for the same; storage battery watt meters showing the state of charge of a storage battery; and new switch board instruments. The discussion following was generally taken part in by the members and was in the main an exchange of experiences with meters.

The committee on Acetylene gas and Welsbach burners presented a report, which was accepted.

WEDNESDAY MORNING.

The report of the treasurer was presented and accepted.

MR. J. W. LIEB, JR., read a paper on "Methods of Charging For Current." He discussed ten methods in use as follows: Flat rate. Flat rate with connection to circuits shut down at agreed hours. Discounts based on duration of demand, based on the stated time of closing of the customer's premises. Special rates for motors. Discounts on gross bills. Discounts based on average use per day of units installed. The Hopkinson system, a fixed annual rental based on customer's load factor, and an additional charge per unit used. Double discounts, one on gross bill and a second discount based on average use of installation. The "Wright" system, with demand meter. The Kapp, or double rate system; maximum rate being charged at the hours of the peak of the station load and a lower rate during the remainder of the twenty-four hours. And he presented a set of tables showing the rates and methods of charging of twelve large stations.

MR. A. S. KNIGHT, of Boston, in a written discussion, acknowledged the value to the industry of the analysis of costs, which had been made and published by English electric light men; particularly Mr. Arthur Wright; admitted that American rates had been generally made with too little analysis of cost of product, but objected that the Wright system went too far in the other direction by disregarding the wholesale feature of sales to large consumers.

MR. W. S. BARSTOW read a written discussion and showed diagrams which emphasize the effect of cost of product at different hours of the demand variation from hour to hour; and accepted the value of a high load factor in reducing possible selling price. He recommended the double rate system of charging with a constant minimum rate in effect at all but the "peak" hours; the minimum rate being calculated to begin with and any readjustment toward lower rates due to reduced cost of production to be made by lengthening the hours during which the minimum rate should be in effect. The "Kapp" system and a Kapp meter made from one of the common type of meters by the addition of a self-winding clock attachment, were his preferences as to the manner of applying the double rate.

A general discussion ensued, questions being asked of the delegates who had spoken in order to elucidate their methods of apportioning costs of production, and the subject being one of special interest it was resolved to take it up again at the evening session.

WEDNESDAY EVENING.

The discussion was continued in general, many delegates taking part, the experiences and opinions of each being given. To such an extent were confidential statements of experience gone into that even the official stenographer was instructed to take no notes.

THURSDAY MORNING.

MR. CHARLES E. PATTISON presented a paper entitled, "Storage Battery Progress and Results in the Edison Boston Stations." The paper embodied a record of three years and six months' experience with the first battery, two years and three months with the second and one year with the third. His conclusions were that his company's experience to date indicated great benefits from the batteries and that while they had weaknesses, the expense of maintenance was not so great as for some of the other apparatus in use. The most notable benefits were the better regulation of pressure on the system, particularly the elimination of fluctuation due to intermittent motor loads, such as direct connected elevators; the improvement of generating economy due to the custom of charging the batteries during hours when the load would otherwise be light and the reduction of expense hitherto necessary in keeping furnaces banked and engines ready for emergency use.

The discussion by Mr. R. R. Bowker, Mr. W. S. Barstow, Mr. J. W. Lieb, Jr., Mr. L. A. Ferguson, Mr. Samuel Scovil and others showed differences of opinion among the members having experience with batteries as to which of the advantages to be gained by their use was of primary importance, the expressions varying between those given by Mr Pattison and that of another delegate who was of the opinion that the immediate availability of the battery as a reserve in case of accident to the generating plant was its principal recommendation.

MR. J. W. LIEB, JR., presented the report of the committee on storage batteries, which, among other matters, contained a recommendation that a rating of battery capacity more conservative than that heretofore in use by the manufacturer should be adopted.

The report of the executive committee and the report of the Lamp Testing Bureau, presented by Mr. Wilson S. Howell, the chief of the Testing Bureau, were read and referred to the afternoon session for discussion.

THURSDAY EVENING.

The reports referred from the previous session were fully discussed, and after electing officers and executive committee for the ensuing year, the convention adjourned.

The following is the list of officers elected: President, Samuel Insull, Chicago, second term; vice president, R. R. Bowker, New York, second term; secretary, Wilson S. Howell; treasurer, W. S. Barstow, Brooklyn; executive committee, Charles L. Edgar, Boston; Alex. Dow, Detroit; George R. Stetson, New Bedford; J. W. Lieb, Jr., New York; Samuel Scovil, Cleveland.

Among those present were the following:

Geo. A. Redman, Rochester, N. Y., Gas and Electric Co.; A. M. Robertson, secretary and general manager, Minneapolis, Minn., General Electric Co.; J. S. Crider, Edison Co., Cumberland, Md.; A. W. Field, secretary and manager, Columbus, O., Edison Co.; Geo. H. Finn, Edison Electric Light and Power Co., St. Paul; Wm. G. Beale, counsel, Chicago Edison Co.; Warren H. Girvin, general manager, Edison Light and Power Co., Syracuse, N. Y.; Geo. W. Davenport, treasurer, Electric Light and Power Co., Syracuse, N. Y.; W. M. Anthony, comptroller, Chicago Edison Co.; Alex. Dow, general manager, Edison Illuminating Co., Detroit, Mich.; J. W. Lieb, Jr., general manager, Edison Co., New York; C. L. Edgar, vice-president and general manager, Edison Co., Boston, Mass.; Hoyt Post, director, Edison Co., Detroit and Grand Rapids, Mich.; Leon H. Scherck, Edison Co., New Orleans, La.; Charles R. Price, treasurer, New Bedford, Mass., Gas and Edison Light Co.; John W. Howell, E. G. E. Lamp Works, Harrison, N. J.; R. R. Bowker, first vice-president, Edison Electric Illuminating Co., New York; J. Colby, treasurer and general manager, Des Moines, Ia., Edison Light Co.; M. A. Beal, secretary and treasurer, Forest City Electric Light and Power Co., Rockford, Ill.; W. S. Smith, superintendent, Toledo, O., Consolidated Electric Co.; W. H. Johnson, secretary and manager, Edison Co., Philadelphia, Pa.; Charles G. King, Chicago Edison Co.; Wm. Chandler, Edison Electric Co., Sault Ste. Marie, Mich.; Samuel Insull, president, Chicago Edison Co., Brooklyn, N. Y.; Chas. E. Pattison, Edison Electric Illuminating Co., Boston, Mass.; L. A. Ferguson, Chicago Edison Co., Chicago, Ill.; Geo. P. Magner, treasurer, Newport Illuminating Co., Newport, R. I.; Luther Stieringer, Edison Electric Co., New Orleans, La.; T. C. Martin, The Electrical Engineer; John B. O'Hara, Western Electrician, Chicago, Ill.; John Kruesi, General Electric Co.; John McGhie, General Electric Co.; S. D. Greene, General Electric Co.; John Jay Abbott, Chicago Edison Co.; W. H. Francis, Boston Edison Co.; C. C. Perry, Indianapolis Electric Light and Power Co.; Geo. R. Stetson, president, New Bedford, Mass., Gas and Edison Light Co.; Chr. Wustenfeld, manager, Elgin City, Ill., C. & A. Ry. Co.; A. S. Knight, Edison Co., Boston, Mass.; James T. Humbird, Edison Co., Cumberland, Md.; Aug. Smith, president, Appleton, Wis., Electric Light and Power Co.; Martin J. Insull, Sargent & Lundy, Chicago, Ill.; R S. Hale, Boston, Mass.; Chas. Batcheler, Chas. D. Shain, Electricity; H. T. Edgar, W. M. Habishaw and Wallace S. Clark; W. S. Barstow, general superintendent, Edison Co., Brooklyn, N. Y.; J. R. Lovejoy and M. K. Eyre, General Electric Co.; E. A. Doty, president, and R. C. Peabody, secretary and treasurer, Brooklyn Edison Co.; C. R. Huntley, George Urban and H. G. Stott, Buffalo General Electric Co.; R. Van Trump, Wilmington (Del.) Edison Co.; J. G. Crossman, electrician, Atlanta Edison Co.; S. Scovil, vice-president, Cleveland Edison Co.; W. A. Stadelman, Elwell-Parker Co.; Prof. S. H. Short and H. McL. Harding, Walker Mfg. Co.; I. L. Roberts and O. E. Dunlap, Niagara Falls; T. C. Frenyear, Buffalo; Allen R. Foote, Tacoma Park, D. C.

CONVENTION NOTES.

ELECTRICAL ILLUMINATION OF THE WHIRPOOL RAPIDS.

ONE of the novel sights vouchsafed to the members attending the convention of Edison Electric Illuminating Companies at Niagara Falls was afforded by an experiment arranged between Supt. J. K. Brooks of the "Great Gorge Route," Mr. Luther Stieringer and the General Electric Company. Briefly it was the illumination of the Whirlpool Rapids by powerful searchlights. The idea originated with Mr. Luther Stieringer, whose experience with searchlight effects on moving waters gained from the electric fountains at the World's Fair at Chicago, which he designed, enabled him to gauge the probable success of his experiment. Mr. Brooks arranged the car and the lights and provided the current, while the General Electric Company furnished the searchlights and colored screens.

The illumination was merely in the nature of a trial demonstration of the feasibility of realizing Mr. Stieringer's idea, which comprehends ultimately the illumination of the Whirlpool Rapids nightly during the season, on a very much larger

and more substantial scale. The methods adopted in this instance were somewhat crude, owing to the shortness of time in which arrangements had to be made.

Six standard General Electric Company's searchlight lamps were employed. They were set in six plain wooden boxes, painted dead black inside. Back of each arc lamp, attached to the back of the box, was a polished silvered reflector. The boxes were placed on one of the flat cars of the Great Gorge Railway and the lights were controlled by a rheostat also on the car. A start was made from the Cataract House at 8:30 p. m. on Wednesday night in special cars under the immediate charge of Supt. Brooks. Many of the party had no idea of what they were about to contemplate. Arrived opposite the point in the Whirlpool Rapids where the movement is most turbulent the lights on the cars were suddenly extinguished. The moon had not risen and the gorge was a huge cave paved with a hurrying, leaping mass of grayish water and roofed with the almost black sky. The scene was impressive.

The small switch on one of the uprights of the car was suddenly closed by Mr. Brooks. Instantaneously the beams of light concentrated into one, flashed out upon the Rapids. The effect thus produced evoked admiration from the favored spectators. The intensity of the white light upon the masses of tumbling, roaring waters was more than magical. It was a new view of the Rapids, and conveyed perhaps a better idea of the force and violence of the current than can be gained under the light of day.

To endeavor to improve on this seemed an anti-climax, but Mr. Stieringer had another treat in store. He had provided a series of colored screens to see what effect colored beams would give to the water. The red screen was lowered in front of the reflectors. The water now assumed an almost blood red hue. From the cars this burst of color in the inky blackness of the surrounding was weird. From the top of the gorge bank the effect was almost diabolical.

The lamps were left lighted during the return journey, throwing colored beams on the foliage, and no part of the Whirlpool Rapids but was momentarily illuminated by the concentrated beam of white light. The experiment was such as to demonstrate that no visitor to the Falls hereafter will care to go away without seeing the beautiful and novel spectacle of the illumination of the Rapids.

THE NIAGARA CONVENTION is said by the Edison men to have been the most successful held. The attendance was large, the papers and discussion were excellent, and the entertainments delightful. All the reports of improving conditions of business were highly encouraging and many plans of extensions came to the surface. President Insull is deservedly to be congratulated, not only upon the success of the meeting, but upon the honor paid him of re-election.

ONE OF THE FEATURES of the convention was the entertainments organized under the charge of Mr. Wilson S. Howell. Tuesday, Wednesday and Thursday mornings there were tally-ho rides for the ladies, of whom some twenty or thirty were present. On Tuesday afternoon the Niagara power house was visited. Wednesday afternoon a splendid trolley ride was had from Chippewa to Queenston on the Canadian side and Lewiston to the hotel, on the American side coming up the Gorge Road. On Wednesday evening a large party went down the Gorge Road to the Whirlpool Rapids to see Mr. Stieringer's experiments with colored search lights. Thursday morning an early trip was made on the "Maid of the Mist." And so it went on till Friday morning came, when the convention broke up and hied home.

DR. COLEMAN SELLERS and Mr. L. B. Stillwell were very kind in the attentions shown by them to visitors to the power house, many of whom are deeply interested in the practical side of the transmission work.

PROF. S. P. THOMPSON dropped in by chance from the Rockies on Wednesday evening and went on the same night to spend the following day with Mr. Steinmetz at Schenectady. The Dublin delegation attending the street railway meeting made also many acquaintances among the Edison men through Mr. Parshall.

THE EDISON BADGE had a portrait of "the old man," of whom also a good picture appeared on the Cataract House dinner menus.

MR. W. S. BARSTOW, secretary, is entitled to many thanks for his care and kindness to visitors and supply men attending the convention, who, although not given the password for the meetings, were shown every attention and made to feel quite at home.

THE GENERAL ELECTRIC COMPANY was well represented at the convention of Edison Electric Illuminating Companies as befitted its position in regard to them. The representatives in attendance were S. Dana Greene, H. W. Darling, John Kruesi, C. T. Hughes, M. K. Eyre, J. McGhie, A. D. Page, John W. Howell, C. D. Haskins, F. M. Kimball, S. B. Paine, W. S. Andrews and W. J. Clark. In one of the rooms of the Cataract House, directly behind the convention hall, the General Electric Company made an exhibit especially for the Edison people. Upon a switch board were mounted examples of their incline coil instruments, the edgewise instrument for feeder board service, a large "G 2" astatic ammeter for recording the total output of stations calibrated to 2000 amperes, a direct current astatic ammeter. A sample of the new Thomson recording watt meter especially designed for use by Edison Electric Illuminating Companies was also shown, as well as a lamp inspectors' indicating watt meter. Upon a table were laid samples of the new porcelain cutouts developed by the General Electric Company, sections of its wires and cables and examples of underground junction boxes and distribution boxes. To explain the manufacture of type "H" transformer, there were shown the component parts of a transformer in the different stages of manufacture. The exhibit also comprised samples of the single solenoid arc lamp and of the lately developed alternating current enclosed arc lamp. The exhibit was completed by two one-horse power motors, one for 500 volts and the other for 220 volt circuits. The room was hung with the diplomas which the company has taken at different expositions and photographs of some of its more important works. A full supply of literature was provided for the use of the delegates. For the Street Railway Association the company made no separate exhibit. It was represented by Mr. W. G. Clark, the manager of its railway department, and Mr. H. Beach.

DR. W. M. HABIRSHAW was present in the interests of the India Rubber and Gutta Percha Insulating Company, which is now doing a large amount of new work for the Niagara power house and transmission purposes.

GENERAL INCANDESCENT ARC LIGHT COMPANY, of New York City, made an excellent display of their admirable specialties in one of the parlors of the Cataract House. It was under the charge of Mr. E. Lavens, general manager, assisted by Mr. H. Swoboda, the electrician of the company. It included a full line of their "Unique" long life arc lamps, some of which have burned as long as 165 hours, while their length is only twenty-seven inches in the "Bijou" forms. There are many notable features of simplicity about the mechanism of the inner globe and the devices for adjustment and renewal. The lamps are very handsome in make and finish and in large use by lighting companies, notably several of the large Edison. The company also showed their well known "Quick Break" types of blade switches, with great carrying capacity, instantaneous action, the breaking blade light with high tension spring and so small an arcing flash that the blade stands prolonged use. Other excellent devices shown were the Bergmann flush push switches, the Bergmann attaching plug, with lidded flush receptacle, the Bergmann volt meter and ground detector switches, only the dial and pointer showing on the face of the board; and other standard and popular apparatus for central station work.

FIFTEENTH ANNUAL CONVENTION OF THE NEW YORK STATE STREET RAILROAD ASSOCIATION.

THE fifteenth annual meeting of the New York State Street Railway Association was held at the International Hotel, Niagara Falls, N. Y., Sept. 14, 15 and 16, 1897.

PRES. J. TRACY ROGERS, of Binghamton, called the meeting to order on Tuesday morning at 10:45 o'clock.

The following gentlemen were in attendance at the meeting: Boyle, John W., president Utica Belt Line Street Railroad; Brewster, J. C., superintendent N. F. & S. B. R. R. Co.; Cahoon, J. B., general manager Elmira & Horseheads Railway Company; Clark, J. E. P., general manager Binghamton Railroad Company; Cooper, H. S., Schnectady Railway Company; Cole, Wm. W., West Side Railroad Company, Elmira; Cleminshaw, Charles, president Troy City Railway; Danforth, R. E., Buffalo, Bellevue & Lancaster Railway; Ely, W. Caryl, president N. F. & Buffalo Railway Company; Evans, H. C., Nassau Electric Railroad, Brooklyn; J. H. Stedman, Rochester, Railway Company; Fearey, Thomas H. Buffalo, N. Main St. & Tonawanda Railway Company; Havens, Wm., superintendent Citizens Street Railway Company, Fishkill-on-Hudson, N. Y.; Heller, W. M., Lewiston & Youngston Frontier Railway, Lewiston, N. Y.; Charles B. Hill, Niagara Falls & Suspension Bridge Railway; Johnson, A. L., president Nassau Railroad, Brooklyn; Johnson, Henry A., Metropolitan Street Railway Company, New York; Morgan, Godfrey, Buffalo St., Main St. & Tan. Railway Company; Marshall, C. K., N., F. & B. Railway, Niagara Falls, N. Y.; McCabe, Ambrose P., Metropolitan Street Railway Company, New York; Mooney, F. P., C. & H. Traction Company, Cortland, N. Y.; Maloney, F. G., Elmira & Horseheads Railway Company; Maffitt, John

H., the Rapid Transit Railway Company, Syracuse, N. Y.; McCormack, J. H., general superintendent Brooklyn Heights Railway Company; McNamara, John W., the Albany Railway Company; Newton, Henry S., Syracuse Rapid Transit Railway Company; O'Connor, Edmund, attorney of Association; Porter, B. W., Saratoga Traction Company; Porter, Alex J., director N. F. & S. Railroad; Penington, T. C., secretary American Street Railway Association; Rogers, G. T., president Binghamton Railroad Company; Sliney, George H., Nassau Railroad Company; Smith, Charles H., superintendent Troy City Railway; Story, C. B., Hoosic Railway Company; Seixas, E. F., Amsterdam Street Railway Company; Vanhorn, Burt, N. F. & B. Railway; Fearey, Thomas H., president Canandaigua Electric Railroad Company; Wheatly, W. W., secretary Brooklyn Heights Railroad Company; Watson, Henry M., president Buffalo Railway Company; Deming, Peter C., Buffalo Railway Company, Buffalo, N. Y.; Nicholl, T. J., Rochester Railway; Read, John A., Tonawanda Railroad Company; Waite, E. B., Tonawanda Railroad Company; Phillips, W., Niagara Falls Park and River Railway, Niagara Falls, Ont.; VanEttan, Ames, Kingston City Railroad Company, Rondout, N. Y.; Barnes, C. R., inspector State railroad commission, Rochester, N. Y.

Allison, Giles S., St. Louis Register Company; Toby, A. E., the Pennsylvania Steel Company; Adams, H. E., Central Electric Company; Beach, R. H., General Electric Company; Wm. J. Clark, General Electric Company; Evans, H. C., the Johnson Company, New York, N. Y.; Fearey, Thomas H., General Electric Company; Granger, J. A., New York Car Wheel Works; Haskell, G. W., J. G. Brill Company; Hollbrook, Percy, Weber Joint Manufacturing Company; Jackson, Geo. J., National Conduit and Cable Company; Lawless, E. J., American Car Company; Long, E. T., Peckham Motor, Truck and Wheel Company; Morris, Elmer P., McGuire Manufacturing Company; MacGovern, Rossiter, MacGovern & Co.; Morrell, Frank A., Sterling Supply and Manufacturing Company; Manson, George T., the Okonite Company; Pugh, D. W., the Stephenson Company; Polk, R. K., William Wharton, Jr., & Co., Philadelphia; Ransom, H. N., Consolidated Car Heating Company; Sheble, Edison-Brown Rail Bond; Swan, G. W., John A. Roeblings Sons Co.; Ten Broeck, Wm. H., Diamand Truck and Car Gear Company, Kingston, N. Y.; Vosburgh, A. C., the New Process Rawhide Company, Syracuse, N. Y.; Vincent, C. A., vice president the Ball & Wood Company, New York; Walsh, C. N., McIntosh, Seymour & Co., New York, N. Y.; Watson, H. D., the Edw. P. Allis Company, Milwaukee, Wis.; Potter, D. F., General Electric Company, Buffalo, N. Y.; McGhie, J., General Electric Company, New York, Peckham, E. Peckham Truck Company; Estey, F. A., R. D. Nuttall Company; Sharp, Edward P., Buffalo, N. Y.; Smith, Pemberton, New York Car Wheel Works; Shippy, H. L., John A. Roeblings Sons & Co.; Wood, Charles N., R. D. Nuttall Company; Randall, F. C., Christensen Engineering Company, Hartford, Conn.; Vosburg, A. C., secretary and treasurer the New Process Raw Hide Company.

Anderson, Edgar P. Dublin United Tramways Company; Beeton, S., Dick, Kerr & Co., Hove, Sussex; Anderson, Wm., secretary and manager Dublin United Tramways Company; Baker, Frank M., Cole, Ashley W., DeFriest, George W., State railroad commissioners; Concanon, J. B., Dublin, Southampton, Barcelona & Tramway Union Company, London, Eng.; Dick, inson, Alfred, European Tramways, Birmingham, England; Flett, George, managing director Dick, Kerr & Co., London; Murphy, J. F., Dublin Tramways, Dublin, Ireland; Murphy, Wm., Martin, Dublin & Belfast Tramway, Dublin, Ireland.

THE PRESS—Electricity, Charles D. Shain; The Electrical Engineer, T. C. Martin; Electrical Review, Charles W. Price; Electrical World, L. H. Parker; Street Railway Journal, Jas. H. McGraw and W. H. Taylor; Western Electrician, J. B. O'Hara; stenographer, T. E. Crossman; Street Railway Review, F. S. Kenfield.

THE RAILWAY COMMISSIONERS of the State, Messrs. Ashley W. Cole, C. R. De Friest and F. W. Baker, were present and took a close interest in all the proceedings.

PRESIDENT ROGERS delivered a long and able address in review of the affairs of the Association. He spoke of the poor earnings of the past year, as the most discouraging since the beginning of the "rapid transit," but regards prospects as brighter. Owing to liberal expenditures, street railroads were now earning less per car mile than under the horse car period, but it was also true that it was the first year for some time that a receiver had not been asked for to take charge of some road in the State. He reviewed the various questions of interest to the members and spoke of the Association as having proven a tower of strength to its members.

SECRETARY ROBINSON read the report of the executive committee, showing a membership of no fewer than forty-eight street railway companies, receipts of $7,687 and a balance of $1,361.

MR. W. W. WHEATLY, of Brooklyn, read a paper on "How Can We Increase the Efficiency of Employees?" which was favorably discussed by Mr. Cahoon and Mr. Anderson, of Dublin.

MR. W. J. CLARK then presented a most valuable paper full of statistics entitled: "A Decade of Electric Railway Development," in which, by a series of exhaustive tables and comparisons, he brought out a number of points in favor of the electric street railway system of to-day.

MR. T. J. NICOLL, of Rochester, presented a forcible argument in favor of a complete and careful mileage account, his paper being "The Advantages of a Car Mileage Record."

MR. W. W. COLE, of Elmira, in a paper entitled, "Facts and Fancies of Railroads," made a clever and vigorous arraignment of newspaper yarns about the street railway and the visionary ideas of municipal ownership.

MR. H. S. NEWTON, of Syracuse, in a paper on "How To Obtain the Best Results in Track Building," explained some excellent ideas in track construction and "bonding."

JUDGE MCNAMARA discussed this and the preceding paper.

MR. C. L. ROSSITER'S paper on "The Advantages of Up-to-Date Street Railroad Service," was read in his absence by the secretary and was a forcible argument drawn from Brooklyn experience, why fares should not be reduced, as they had been really reduced very materially already, in longer rides, better service, etc.

MR. R. DUNNING, of Buffalo, presented a terse paper on "The Repair Shop," describing a practical equipment.

This completed the work of the morning and afternoon sessions. At the close of the afternoon session a group portrait was taken. The annual banquet was held in the evening.

WEDNESDAY.

MR. H. H. VREELAND, president of the Metropolitan Traction Company, New York, presented a paper dealing trenchantly with the subject of "Municipal Ownership" and its fallacies.

MR. H. S. COOPER, of Schnectady, N. Y., read a paper on "The Prevention of Accidents; the Best Method To Accomplish This End."

MR. C. L. ALLEN, of Syracuse, N. Y., read a paper on "Low Joints; How To Prevent Them."

MR. F. D. RUSSELL, of Rochester, N. Y., read a paper entitled, "Street Car Wheels; Should They Be Made Heavier?"

The election for officers for 1897 resulted as follows: G. Tracy Rogers (re-elected), president; W. Caryl Ely (re-elected), first vice president; J. T. Nicholls, second vice president; secretary and treasurer (re-elected), Henry A. Robinson. The executive committee: Messrs. H. H. Vreeland, J. W. McNamara, H. M. Watson, C. L. Rossiter.

MR. J. P. CLARK secured the carrying of a resolution for the appointment of a committee of five to co-operate with the Railroad Commissioners of the State in framing uniform, standard rules to govern the operation of street railroads in the State. The committee appointed was H. H. Vreeland, C. L. Rossiter, A. L. Johnson, H. H. Littell and J. W. McNamara.

The 1898 meeting will be held in Brooklyn.

CONVENTION NOTES.

THE TOASTS at the Street Railway banquet at the International on Tuesday night were as follows: Toastmaster, Hon. W. Caryl Ely. Welcome, Hon. Arthur C. Hastings; "The Empire State," Hon. James M. E. O'Grady; "The Niagara of To-day," Hon. Thomas V. Welch; "Street Railroads From the Consumers' Standpoint," John Kendrick Bangs ;"Our Hosts," Hon. Edmund O'Connor; "The Railroad Commissioners," Ashley W. Cole; "Our Transatlantic Visitors," William Murphy, M. P., and J. B. Concannon; "The Association," John W. McNamara; "The Railway Press," J. H. McGraw; "The Ladies," J. H. Stedman; "The Supply Men of To-day," W. J. Clark.

Mr. John M. Brinker was also called upon to make remarks.

THE CENTRAL ELECTRIC COMPANY made a good display of their electric railway specialties and supplies by means of samples, specimen boards, etc.

THE OKONITE COMPANY was represented by Mr. Geo. T. Manson.

MR. ELMER P. MORRIS was present in the interest of the McGuire trucks, Garton-Daniels lighting arresters, Hemingray glass, Monarch paint, Simonds gears and pinions, Point Marion Company's arms; brackets and pinions and Keystone instruments.

AS NOTED in the list of names, there was a good representation of leading supply firms and men, but none of the ex-

hibits were large, and in most cases no attempt was made at an exhibit.

SEVERAL EXCURSIONS to points of interest in and around the Falls were indulged in on Wednesday and Thursday after the serious work of the convention had been disposed of.

FIRE AND POLICE SUPERINTENDENTS' MEETING.

IN accordance with the arrangements made, the International Association of Fire and Police Telegraph Superintendents held their meeting at Nashville, Tenn., at the Maxwell House, on September 14 and 15. This was the second annual meeting of the young society. Papers were presented by Messrs. Brophy and Ayden. An address was delivered by President Frank C. Mason, of Brooklyn, N. Y., in which he stated that the membership was larger than ever and that the association was in good financial condition. He commended the study of modern electrical conditions to the members and praised the efforts of the electro-technical press in disseminating information. The association, he said, was here to stay and would long continue its career of usefulness.

The programme outside the regular meetings and exercises included visits to the excellent Centennial Exposition, an excursion to the famous Belle Mead race horse breeding establishment, and a trip to the summit of Lookout Mountain.

OBITUARY

GEORGE STEWART HEGEMAN.

It is with extreme regret that we announce the death of Mr. George Stewart Hegeman, vice-president of The Hart & Hegeman Manufacturing Company, of Hartford, Conn., who died suddenly at Detroit on Tuesday, September 7, of acute inflammation of the kidneys. Mr. Hegeman left Hartford on August 28 in excellent health, to go to Seattle, Wash., via Montreal. He was taken ill while at Detroit, where he had stopped to visit his sister. His illness lasted less than three days.

Mr. Hegeman was a graduate of the Sheffield Scientific School of Yale College, class of '78, and also of Columbia University Law School. His connection with the company of which he was vice-president, dated from its organization in 1890, and the success of the company has been largely due to his efforts during the first years of its existence. For the past few years he had spent his time in travel, and in looking after his personal interests. Mr. Hegeman was forty years of age and unmarried. His loss will be keenly felt not only by his business associates, but by a large circle of warm friends. The funeral was held at Passaic, N. J., from the home of his parents on Friday, September 10.

LEGAL NOTES

THE CAR HEATER DECISION.

We have received the following communication from Mr. James I. Ayer, general manager of the American Electric Heating Corporation:

The recent decision on car heaters against the West End Street Railway, Boston, refers to some heaters furnished two years ago by the old organization of the American Electric Heating Corporation, similar to those made by another company, but totally unlike the American Company's regular car heater, which was in no way involved in the suit. The suit will be appealed as is usual. The patents under which the American Company's heaters are made fully protect them and the users of them, and have never been called into question, and the American Company report a record of complete satisfaction.

HARTFORD, CONN.—The power plant of the Hartford Electric Light Company on the Farmington River was destroyed by fire last week. This plant furnished a large amount of current for use in Hartford and included two 800 h. p. generators. The loss is put at $70,000. The company will fall back for the present on its old steam plants in Hartford.

EDUCATIONAL

Y. M. C. A. STUDIES IN ELECTRICITY.

The Twenty-third Street Branch of the Y. M. C. A. will open its winter course of electricity the first week in October. It will again be in charge of Mr. Max Osterberg, E. E., A. M., who has lectured there for several years. This year the course will be extended considerably, being divided into two distinct sections, one elementary course starting with the principles of electricity and one advanced course intended principally for stationary engineers, wiremen, electrical workers, in which the engineering principles of lighting, railway and power transmission will be discussed.

Mr. Osterberg will visit a number of interesting installations with his students, to give them object lessons of actual practice. It is also intended to open a course in physics and mechanics if a sufficient number of applicants can be secured. Applicants can get detailed information by applying to Mr. Cox, educational secretary of the branch, 52 East Twenty-third street.

THE STOCK MARKET

A CONSTANT IMPROVEMENT.

There is scarcely any room for doubt that the long heralded tide of prosperity is on the permanent rise. With the continued advance in wheat has come an increased demand for iron, that unfailing sign of activity in all branches. Added to this is the marked increase in railway earnings, notably that of St. Paul, while the truly remarkable increase in bank clearings shows that business men and capitalists are no longer holding back, but are beginning to utilize capital, confident of the stability of the present market.

Electrical securities have shown marked strength during the week past. American Bell continues on its phenomenal upward course, having sold up to 279, with 280 asked, and very little to be had at that figure. There are some that expect to see the stock touch 300 before long. Western Union rose to 96¾, with sales of 62,396 shares for the week. General Electric reached 39, closing at 38½, with sales of 18,407 shares.

REPORTS OF COMPANIES

OUTPUT OF BELL TELEPHONES.

For the month ending August 20 the American Bell Telephone Company increased number of instruments in licensee's hands under rental by 5,613, making this far in 1897 a net gain of 81,544, by far the best August and eight months' exhibit on record. Figures follow:

August—	1897.	1896.	1895.	1894.
Gross output	15,767	9,675	11,009	5,689
Returned	10,154	7,850	8,730	6,531
Net output	5,613	1,825	2,279	*842
December 21 to August 20—				
Gross output	143,545	136,353	109,905	53,144
Returned	62,001	61,517	55,851	46,984
Net output	81,544	74,836	54,054	6,160
Total outstanding August 20	853,833	822,823	679,514	581,163

*Net loss or decrease in telephones under rental.

NEW YORK EDISON COMPANY'S EARNINGS.

The following gives the figures for last month's business of the Edison Electric Illuminating Company:

	August. 1897.	August. 1896.	Increase.
Gross	$170,347.66	$155,010.91	$15,330.75
Net	66,222.59	54,379.31	11,843.28
Gross, 8 months	$1,561,567.45	$1,417,812.87	$143,754.58
Net, 8 months	696,971.61	596,182.86	100,788.75

TRADE NOTES & NOVELTIES

INCREASE IN THE C & C ELECTRIC COMPANYS' GROWTH.

In order to properly care for the large growth in their business, which the C & C Electric Company are now experiencing, they are not only daily increasing their factory force and capacity, but are increasing their office and selling force as well.

Among the late acquisitions to their selling force is Mr. S. L. Nicholson, who is to look after machinery sales in Greater New York and vicinity, under the supervision of their sales manager, Mr. Campbell Scott. Mr. Nicholson will bring to the assistance of the C & C Company a thorough experience in the electrical business extending over ten or eleven years. His experience has been gained with the old Sprague Motor Company, the Wenstrom Company, the Short Company and several others of equal note, besides, more recently, with the Cutter Electric Manufacturing Company, of Philadelphia. In Mr. Nicholson the C & C Company feel that they have made a valuable acquisition to their force, both on account of his experience in selling and installing electrical apparatus, and his high standing as a gentleman.

OVERLOADED IRON CLAD RHEOSTATS.

The Iron Clad Rheostat Company reports an interesting case of overload on one of their rheostats. In experimenting with some special resistance wire, they made up one of their regular plates 8 inches by 8 inches by 1½ inches, having a surface area of 243 square inches, with 2 ohms resistance in the winding. This plate was laid flat on a table, and a current of 22 amperes forced through it for 20 minutes. The current was then increased to 28 amperes for 10 minutes more, and then forced up to 33 amperes. The entire plate soon began to glow with a bright red heat, yet continued to carry the above current for over 20 minutes before burning out, which it did in the most quiet manner possible, the only visible action being a bright red spot moving about the plate as the arc burnt its way from one part to another. This process alone occupied over one minute, and there was entire absence of the usual pyrotechnic display, incident to a "burn out" on heavy current. During these last 20 minutes the plate was dissipating approximately 2,700 watts, more than ten times its rated capacity.

ANOTHER SALE OF APPARATUS FOR ENGLAND.

The Westinghouse Electric and Manufacturing Company has received from its European company notice of the award to it by the Metropolitan Electrical Supply Company of the contract for a large electric lighting plant to be installed in London. The apparatus will be of the multiphase type, involving the use of the Tesla patents, which are owned in England by the Westinghouse Company. It is understood that the contract amounts to between $350,000 and $400,000.

ARMORITE IN NEW YORK.

MR. R. B. COREY, 711 Havemeyer Building, New York, has been appointed by the Armorite Interior Conduit Company to take charge of the metropolitan district, in the interests of Armorite conduit. This conduit has recently been passed by the National Board of Fire Underwriters and the Fire Department of the city of New York, and it is Mr. Corey's intention to carry a large stock in this city, so that all orders for this vicinity may be filled promptly. The demand for Armorite is steadily increasing, and with first class facilities for manufacture at Pittsburg the Armorite Company are in good condition to fill all orders, however large, expeditiously.

ADVERTISERS' HINTS

THE NEW YORK TELEPHONE COMPANY, in calling attention to the convenience of their service, state that there are 19,500 telephone stations in this city alone.

THE MIANUS ELECTRIC COMPANY, Mianus, Conn., advertise telephone and electrical supplies. Their stock is at all times large and replete.

THE D. & W. FUSE COMPANY, Providence, R. I., claim to be making the "Only" non-arcing fuse on the market for switchboards, transformers, motors, etc. It has been approved by the National Board of Underwriters.

EDWARDS & CO., 144th street and Fourth avenue, New York, have recently brought out a Ruhmkorff coil guaranteed to work on high or low potential. They also advertise the "Eco" bells and buzzers with no adjustments to be displaced. The buzzers are made in five sizes and the bells with 1 inch to 5 inch gauge.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., illustrate the machine shop built by them for the Ball & Wood Company, at Elizabethport, N. J.

THE WESTON ELECTRICAL INSTRUMENT COMPANY, Newark, N. J., draw notice to their standard portable direct-reading instruments. Their price lists 8 and 9 describe them fully.

F. A. BAUX, Chamber of Commerce Building, Chicago, Ill., offers some special bargains, multipolar generators and motors, incandescent lighting machines, switchboards, switches, etc.

WILLIAM D. MARKS, 901 Montgomery avenue, Philadelphia, Pa., may be consulted on all matters related to electrical or mechanical engineering. His specialty is the reorganization of finances and machinery of unprofitable electrical enterprises.

KIELEY & MUELLER, 17 West Thirteenth street, New York, advertise the Kieley steam trap, pressure regulators and damper regulators, especially adapted for electric and high pressure plants.

THE GENERAL ELECTRIC COMPANY recommend their inclined-coil, portable, alternating current instruments as indispensable to station managers. The advantages claimed for them are permanency, accuracy under all conditions, high grade and low price.

THE STIRLING COMPANY, Chicago, Ill., refer to a remarkable physical test of their boilers, described on another page in this issue.

THE BALL ENGINE COMPANY, Erie, Pa., illustrate the evolution in governing devices since 1883. This includes an illustration of their August, 1897, governors.

THE INTERIOR CONDUIT AND INSULATION COMPANY, 527 West Thirty-fourth street, New York, say the broad fundamental patents covering their process of manufacture prevent even an approach to the features wherein lie the strength and integrity of insulation possessed by their standard iron-armored insulating conduit.

WESTERN NOTES

ELECTRIC APPLIANCE COMPANY, Chicago, are well pleased with their experiment of carrying in stock in Chicago a line of porcelain in all styles and sizes of knobs and tubes, that would enable them to fill any order. The advantage of having this stock in Chicago, instead of having to go to the factories for this material, seems to be appreciated by the trade, and the Electric Appliance Company are reaping very satisfactory results. They are the Chicago depot for one of the largest porcelain works in the country, and a customer's requirements must be very severe, indeed, which cannot be satisfied directly from the Electric Appliance Company's stock.

THE WESTERN ELECTRIC COMPANY'S non-sparking brush, which is manufactured under patents controlled exclusively by that company, is being extensively advertised and pushed and is meeting with satisfactory results.

ADAMS—BAGNALL ELECTRIC COMPANY, Cleveland, Ohio, have recently installed 300 series-burning enclosed arc lights for the Lowell Electric Lighting Corporation, Lowell, Mass., for lighting the streets of the city.

WALKER COMPANY, of Cleveland, Ohio, have just issued an interesting circular, No. 1049, on "How to Select a Dynamo," which enters into and illustrates the various points that deserve study in purchasing generators for any class of work.

WILLARD ELECTRIC AND BATTERY COMPANY, of Cleveland, O., have received an order from the Riker Electric Motor Company, of Brooklyn, for several storage batteries to be used in operating motor carriages. These batteries have a capacity of 40 amperes per 30 ounces of active material in the positive plate, and a total capacity of 65 ampere hours. The Willard batteries have been selected, it is said, because of being the lightest batteries for their capacity that are now placed on the market.

WILLIAMS & ABBOTT CO., of Cleveland, O., report an unprecedented demand for their magneto bells for telephone work, necessitating a night shift of men. The outlook continues excellent.

THE UPTON LONG BURNING MIDGET LAMP in its original form, adapted to burn singly on 110 volts, has proven to be such a success that several modifications of it have been designed, including the Midget long burning lamp to burn two in series on 220 volts, a Midget lamp to burn five in series on 500 to 550 volts, and a Midget high tension series lamp to burn on series arc circuits of from 4½ to 7 amperes. All of these lamps are giving remarkable results, and having a very large sale. The Midget Upton Lamp is one of the Electric Appliance Company's specialties, and they are pushing it with their usual energy.

NEW YORK NOTES.

NEW YORK TRAVEL.—The volume of passenger traffic, surface and elevated, is increasing in much more rapid ratio than the population. In 1890 the total number of passengers carried within the city limits was 406,000,000. In 1894 it was 448,000,000. In 1895 the aggregate had reached 469,000,000, and last year it was 526,000,000, an increase of 57,000,000 passengers in a single year. The projected tunnel scheme now before the special rapid transit commission, is figured to take care of 200,000,000 more per annum.

CHESLEY ELECTRIC COMPANY, W. S. Chesley president, have removed their main office from their Hoboken factory to the Havemeyer Building, New York City, where they have taken larger quarters. They have a large stock of second-hand dynamos and engines and have made a good many sales recently. They are also very busy on repair work.

PHILADELPHIA NOTES

STANDARD UNDERGROUND CABLE CO. have opened an office in Rooms 1225 and 1226 Betz Building, Philadelphia, with long distance telephone connection between the office and the Pittsburg factory. This new branch has been placed in charge of Mr. T. E. Hughes, formerly manager of their wire department in New York City.

PHILADELPHIA GAS IMPROVEMENT COMPANY, of Philadelphia, Pa., are increasing their plant by erecting a new fireproof pipe shop, constructed entirely of iron. The building has steel framework and a corrugated iron covering. Contract for erecting the building has been let to the Berlin Iron Bridge Company, of East Berlin, Conn.

ELMER G. WILLYOUNG & COMPANY report a bad fire at 904-6 Nassau street, Philadelphia, occupied by them as a branch shop, where they have also drafting rooms, photograph rooms, glass shop and an experimental laboratory. The place was used principally for the manufacture of induction coils and X-ray apparatus. Loss, $3,000; insurance, $2,500. New quarters have been secured, and all orders are being filled with no delay.

NEW ENGLAND NOTES

PROVIDENCE, R. I.—The Union Railroad Company has awarded a contract for fender equipments for 250 cars to the Parmenter Fender Company, of Cambridgeport, Mass. It is a counterbalanced device, with tripping arrangement, and is automatic, imposing no extra duty on the motorman. The contract calls in all for 500 fenders.

BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have the contract for the new boiler house which the New York Belting and Packing Company are putting up at Passaic, N. J. The building will be entirely fireproof, brick walls, with steel roof trusses covered with the Berlin Iron Bridge Company's patent anti-condensation corrugated iron covering.

MR. C. S. KNOWLES, 7 Arch street, Boston, and 120 Broadway, New York, has issued a very neat and informational circular in regard to his Imperial porcelain, made by the Duggan Imperial Porcelain Works, at Trenton, N. J.

WEST END RAILWAY.—A lease of this great trolley system to the Boston Elevated Railroad Company is proposed, with 8 per cent. dividends guaranteed.

VOL. XXIV. SEPTEMBER 23, 1897. No. 490.

TELEPHONY AND TELEGRAPHY

THE BINGHAMTON, N. Y. TELEPHONE EXCHANGE.

BY HARRY A. GARDNER.

BINGHAMTON, N. Y., because of its beautiful location and the attractiveness of its streets and buildings, has long been known as the "Parlor City." The same enterprise that has given it a beautiful appearance has always been manifested in the early introduction into that city of the great electrical improvements that have marked the closing quarter of the nineteenth century. Within a year of the time that Frank J. Sprague equipped his first electric railroad in Richmond, Va., the horses of Binghamton were shying at the whizzing "broomstick train"; her streets were illuminated with the brilliant arc in the early eighties; and she was among the first to feel the benefits of the distance annihilating invention of Prof. Bell.

The New York and Pennsylvania Telephone and Telegraph

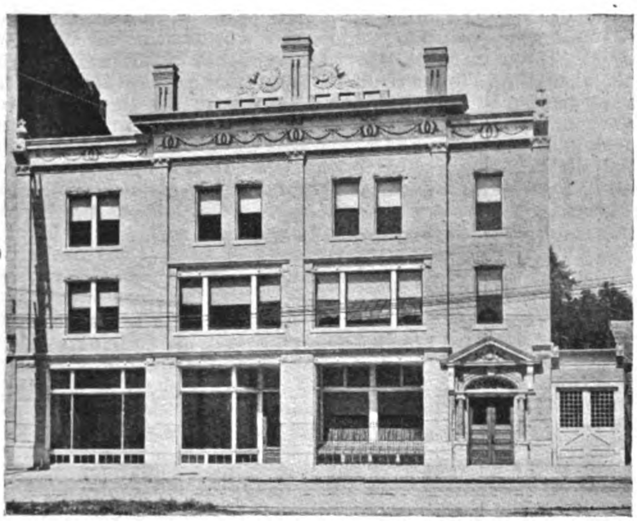

FIG. 1.—BINGHAMTON TELEPHONE EXCHANGE BUILDING.

Company has always been one of the successful branches of the Bell system; and it introduced exchanges in Binghamton, Elmira and other southern New York and northern Pennsylvania towns in the early days of telephony. During the past year this company has been making improvements in Binghamton which give that city as good a service and as finely equipped an exchange as can be found in the country.

Something over a year ago a franchise was obtained from the authorities for the construction of a subway through most of the important streets of the city. The prepared wooden conduit of the Wycoff Wooden Pipe Company, of Williamsport, Pa., was the conduit decided upon. These ducts were placed in the streets last summer, but the work of drawing in the cables was not begun until early this spring. According to the requirements of the franchise, a subway capacity double the present needs of the company was installed.

Since the telephone system was first introduced into the city, the exchange had been located upon the top floor of an office building on the principal business street of the city. With the aerial service no more convenient location could have been selected. But with the determination to introduce an underground system, the managers found what had heretofore been convenience transformed into decided inconvenience. Their requirements had outgrown the former office, and when the question of leading underground cables up through a building that had not been prepared for it, came up, the tearing out that would accompany such a course determined them to seek new quarters. With an underground system established, moreover, they wished to decide upon a permanent location.

Arrangements were finally made whereby a new building was to be erected for their express purpose. This building is

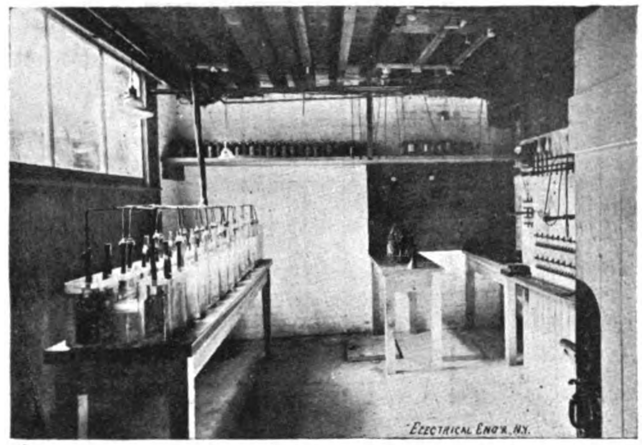

FIG. 2.—BATTERY ROOM AND REPAIR SHOP, BINGHAMTON.

on State street, about two blocks from their former location. It has recently been completed, and the company moved into its new quarters the 7th of July.

The new building, Fig. 1, is peculiar in that the depth is only 20 feet, while it has a frontage of 76 feet. The entire basement, second floor and half of the first floor are devoted to the use of the telephone company. In the basement is a repair shop and battery room, Fig. 2, containing the batteries, the motor-dynamo for charging them, the battery and power switchboard, distributing switch for the electric lights, etc. The business office is located on the first floor. The manager's private office opens out of the business office, as do two sound proof telephone booths. The operating room, testing room and operators' toilet and lunch rooms are located upon the second floor.

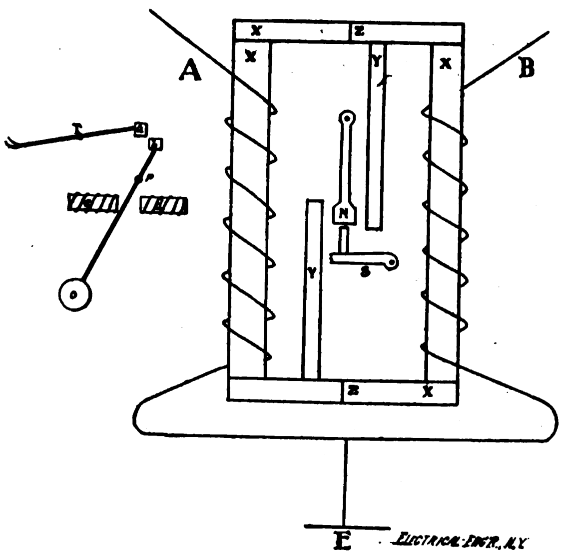
In the equipment of this exchange every detail has been carefully worked out by the efficient electrician of the company, Mr. B. C. Wolverton. Not a superfluous wire or contact has been used, and not a thing left out that could add to the efficiency of the service. A simple switchboard, shown in Fig. 3, consisting of twelve 50-drop panels, was installed, because it was thought that fully as satisfactory a service could thus be secured without the multiplicity of wires, contacts, etc., of a multiple board. Various time-saving devices have

FIG. 3.—THE OPERATING ROOM, BINGHAMTON TELEPHONE EXCHANGE.

been introduced, so that a subscriber can be served with fully as much dispatch and few more movements on the part of the operators than would be required with a multiple board.

In the first place, all telephones will be equipped with a device, doing away with the crank-turned magneto bell, which

is much more simple than anything of the kind heretofore put in general use. This will be accomplished by substituting batteries for magnetos in making calls. One side of the circuit will be grounded at the exchange, and a ground wire will be attached to each telephone in service, which will be so arranged that when a subscriber removes his receiver from the hook, the hook, in rising, makes a momentary contact with the ground, thus closing the circuit through the ground and one side of the line; the momentary current actuates the shutter magnet at the exchange and causes the shutter to open. As the operator inserts the plug in the spring jack to answer



FIGS. 4 AND 5.—MECHANISM OF INDIVIDUAL CALL.

the call, she automatically closes the shutter again. When the subscriber hangs up his receiver after he is done talking, pulling down the hook thereby, another momentary contact with the ground again opens a "clearing out" shutter, thus compelling the subscriber to "ring off" whether he forgets it or not.

Another device does away with much of the talking between the operators at different tables, which was necessary when making connections between panels under the old system. If an operator wishes to connect a subscriber with a number at another panel, she inserts the plug which is already connected with the calling subscriber, in the spring jack which connects with the other panel, at the same time, with a little switch, throwing her telephone in connection with the transmitter of the operator at the other table. The insertion of the plug in the jack lights a tiny lamp at each table, thus notifying the second operator that a number on her board is wanted. This lamp also acts as a guide to tell her in just what spring jack to insert one end of the cord, and as soon as she gets the number required, she can complete the connection with the single motion of inserting one plug in the proper jack; and as she inserts that plug, it extinguishes both lamps, notifying the first operator that the connection is made. When either operator commences to "clear out," the removal of the plug lights

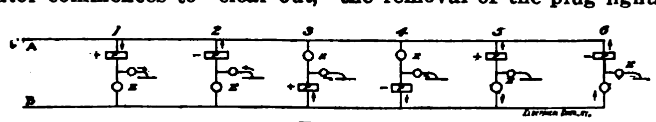


FIG. 6.

the lamps, notifying the other operator that the clearing out has commenced, and as the second operator clears out, the lamps are extinguished, thus announcing that the operation is completed. Thus is obviated all talking between tables, except merely the telling what number is required. The signal lamps used are about ¼ inch in diameter, and are operated by a 4 volt circuit.

Each panel of the board contains a switch, so that if desired the panels can be thrown together in sets of two each; or the panels of any set may be connected and the rest left single. Each set can thus be operated by a single operator. A two-panel multiple board for the long distance or toll lines is placed at one end of the room. The same arrangement of signal lights exists between this board and the city boards.

The chief operator's desk is connected with each panel of the switchboard. In case of trouble on the line, or workmen who are out making repairs calling up, all responsibility is turned over to the chief operator by connecting her with the line in question. She is also able to throw her instrument into connection with the transmitter of any operator at any time, thus being able to keep watch to see that no unnecessary conversation is being carried on.

Another novel feature consists in the flexible cord of the head telephone of each girl being connected to switchboard by means of a plug, instead of being fastened there. When a girl leaves a table, instead of throwing down her instrument, she simply removes the plug and takes it with her. When leaving the building she places it in her locker in the toilet room. The principal object of this is to disconnect the transmitters from the circuit, so that they are not consuming current, except while in use.

While the small generators in the basement are depended on for making all calls, each board is supplied with a hand generator, which can be thrown in by a switch, if, for any reason, the generator cannot be used.

One panel of the switchboard is fitted up for a "selective call" board, to which lines serving more than one subscriber can be brought. It is possible with the system used to place six subscribers on a line. This board is at present wired for twenty lines. The disagreeable feature of a party line, of having some one else ring up or listen while a person is talking, is obviated by this novel improvement. By the use of differentially wound magnets and polarized relays upon the instruments, through which current can be sent in either direction, either through the ground or the two wires of the line, it is possible to work different combinations for calling up any one of the six subscribers wanted and at the same time lock out all the other instruments on that line.

The receiver hook lever of each instrument, which turns on the pivot, r, Fig. 4, has upon the other end a shoulder, a, which, in the normal condition when not in use, is in the position shown. Upon another pivot, p, another lever turns. This lever has upon one end the shoulder, b, and at the other the small disc, o, upon which the words "line in use" are printed. When a subscriber removes his receiver from the hook, throwing his instrument into service, the shoulder, a, lowers, passes by the shoulder, b, and makes it impossible for the second lever to be operated. Every instrument on the line contains a locking magnet, d, and an unlocking magnet, e, which attracts the locking lever either to the right or left, according to which magnet is energized. The same combination of current actuates the magnet, d, in every one of the instruments, and sending the current in another certain manner actuates the magnet, e, in every case.

When any one of the subscribers on the line calls up, the first thing the operator does, before she answers even, is to press a button that sends a current in the proper manner to actuate the locking mechanism of every instrument on that line, except the one calling. She then makes the necessary connections, and the conversation can proceed without fear of interruption or listening on the part of any one else on the line.

When "central" clears out, she presses the unlocking button and sends the current over the line in such a manner that the locks of all the instruments are opened, the levers drawn back to the normal position, and the line is again clear for any one.

When it is desired to call any subscriber, "central" first locks every instrument on the line; then by sending the current in the right direction, the armature of a relay in the instrument of the subscriber wanted is actuated. This armature completes the circuit of the local battery of this instrument and rings the bell, and at the same time actuates another relay which sends current through the unlocking magnet of that instrument only, thus making it possible for this particular subscriber to answer while all the others on the line are still locked out. At the conclusion of the conversation all of the instruments are unlocked and the line is open for every one.

This gives a general idea of the operation of these instruments, but the principle is better shown in Fig. 5.

In Fig. 5, which shows the locking and unlocking device, X X X X are iron strips forming a closed magnetic circuit, Y Y are iron pole extensions, and n a permanent magnet. When the current enters a and b, going to coils and to earth, consequent poles are set up at Z Z, and Y Y are magnetized, one N and one S and n is pulled one way. When current enters at e and goes out at a and b, the action is reversed. S is the hook and n either allows it to move up or prevents it.

In Fig. 6, which shows the manner in which sending the current in different directions operates different instruments, P in each instrument is a polarized relay and E in each case is a neutral relay. Both relays at a station must be closed at the same time to call that station. The neutral relays are closed when no current is passing and the polarized ones are open when no current is passing. Then to call No. 1 connections are so made that the positive pole of the battery con-

nects with line, A; no current goes to line, B, and the negative pole is grounded. Current then flows as shown by arrows in No. 1, closes the polar relay, P, in 1, neutral relay, E, remains closed and the bell rings. The negative relays at 2 and 6 and neutral relay at 5 are open, as are relays, P, in 3 and 4, through which no current has passed. To operate No. 2 the positive pole of battery goes to ground, no current to B, and negative pole to A. The relays, P, at 1, E at 3 and 4, and P at 5, and E at 6, are open, but the negative relay, P, at 2 closes, and no current passing E at 2, it remains closed and the bell rings.

To operate No. 3 the positive pole of battery goes to B, nothing to A, and negative to ground. Relay, P, at 3 closes, neutral remains closed and bell rings, while E at 1, 2, 5 and 6, and P at 4 are open. No. 4 is called by sending positive to ground, negative to B and nothing to A, when P and E at 4 are both closed, while E at 1, 2, 5 and 6, and P at 3 remain open. For No. 5 the positive goes to A and negative to B with nothing to ground, and for No. 6 the positive is sent to B and negative to A.

Current for the switchboard signal lamps and the exchange transmitters is furnished by three Chloride accumulators, rated at a normal discharge of 30 amperes. By an ingeniously arranged switchboard these batteries are so connected that either one or two can be charged while the other two or one are discharging, or all can be charged or discharged at once. As used two are continually discharging while the other one is being charged. The charging is done from a Western Electric motor-generator, which takes current from the 500 volt power circuit of the Binghamton General Electric Company, and transforms it to 6 volts or less.

Current for calling subscribers on the selective call system from central is taken from a series of thirteen storage cells with a rated discharging capacity of 15 amperes. There are two series of these cells, one set being charged while the other is discharging. The subscribers of this system call central by the use of 75 Mesco dry cells. On the ordinary circuits "central" calls subscribers with current from small generators placed in the basement and operated by a small water motor, and the subscribers are aided in calling the exchange by 25 cells of dry battery.

The novel arrangement of many old and some new features in the equipment of this plant has attracted the attention of telephone experts of much larger cities, and the commendation of electricians who have examined the exchange give Messrs. W. N. Easterbrook and E. B. Rogers, of Elmira, the general manager and district superintendent of the company, and W. J. Garvey, of Binghamton, the local manager, a right to be proud of this exchange and to believe that it is one of the finest, for its size, in the country.

DISTURBANCE OF SUBMARINE CABLES BY ELECTRIC RAILWAYS.

The disturbance of submarine cable working by electric tramways forms the subject of a paper by Mr. A. P. Trotter in the Journal of the Institution of Electrical Engineers. As soon as the electric tramway service was started at Cape Town the working of the syphon recorder of the submarine cable of the Eastern and South African Telegraph Company was found to be seriously affected. When the tramcars were started and when they were stopped, "kicks" were recorded by the syphon recorder, and these being superimposed upon the received signals made it difficult and often impossible to read the message. The first mile of the cable was at a mean distance of about half a mile from the tramway. After a long series of experiments Mr. Trotter found that the only way to cancel the disturbances was to lay a new cable of about five miles long, as nearly as possible over the old one, the cable terminating in an earth plate. As soon as this had been done the traffic was resumed, and no appreciable disturbances of the recorder took place. In the discussion upon the paper Mr. W. H. Preece said that similar disturbances occurred wherever electrical tramways and telegraphs, submarine or overland, existed together. Prof. Ayrton gave an account of observations of magnetic disturbances over the whole neighborhood of the City and South London Electric Railway, which runs underground between London Bridge and Stockwell. The suspended magnet used in the investigation showed that disturbances of the earth's magnetic field occurred throughout the whole region of the line, and were caused either by magnets or masses of iron in the passing trains, or by currents passing through the earth.

NEW YORK CITY is now talking to Council Bluffs over the long distance telephone circuits, connections having been completed last week. Omaha was also put in circuit.

A DECADE OF ELECTRIC RAILWAY DEVELOPMENT.[1]

BY W. J. CLARK.

AN eminent writer on railway subjects has substantially said that a railway is a "machine for the manufacture of transportation."

Were we asked, in a single instance, to cover the full meaning of this paper's title, we might respond with such a quotation, for, most certainly, viewing the true objects of a Transportation Company in the broadest manner possible, it is to exemplify this theory, and probably in the whole history of transportation, no class of managers has done so much to create travel rather than to merely take care of what may seem to be the existing demand, as have those of American street railways, since they have had at their command that most

TABLE I.

GENERAL COMPARATIVE STATEMENT OF STREET RAILWAYS IN THE UNITED STATES, JANUARY 1, 1888, TO JANUARY 1, 1897.

	1888.	1897.
Total number of operating companies...	615	806
Number of street railway systems operated by horses	566	167
Number of street railway systems operated by cable	18	38
Number of street railway systems operated by steam dummies (not including elevated)	35	33
Number of street railway systems operated by electricity	21	698
Mileage of horse car track	5,474	1,010
Mileage of cable track	217	515
Mileage of steam dummy track (not including elevated)	216	145
Mileage of electric track	86	13,580

*Elevated and steam railways per passenger. [1]Decrease.

not begin to aggregate the blessings that electric traction has conferred upon those who are frequently the most anxious to condemn it as a motive power. It is with this phase of the situation that this paper will deal, rather than elaborating upon the conquests that have been achieved in the technical and engineering branch.

Going back to the commencement of the present decade, there was in your State but one electric line, some three miles in length, and this particular road, although it enjoys the distinction, Mr. President, of being the nucleus around which you have built an extensive and model electric railway system, you will concede was experimental in its character, and that those other small lines which were contemplated at the same period in New York State were of similar experimental character, so that, commercially, electric traction could not be said to have existed in the Empire State ten years ago; yet, at the present moment there are slightly over 6,000 motor cars in daily use within the territory covered by your association. But to grasp the extent and rapidity of electric railway development, the accompanying comparative statement, covering all the street railways in the United States (and never, I believe, given in this form to the public) will best serve as an illustration.

From such statement it should be noted, not only the tremendous increase in percentage of electric traction to the total, approximately 15,000 per cent., but also the fact that the street railway mileage of the United States has increased over 156 per cent. during the period given. During the same interval the mileage of American steam railways has increased but 31 per cent. This fact in itself would seem to demonstrate that the American street railway men have grasped the possibilities of building up transportation in a more thorough manner than have their brethren of the steam railway fraternity, as well as demonstrating the theory which we have advanced. But for a more immediate illustration of the comparative growth, as well as some other startling facts, let us come nearer home and introduce a comparative statement compiled from the reports of the Railroad Commissioners of the State of New York for the years 1887 and 1896, covering street railways, surface steam railways and steam elevated systems. See page 272.

It may be said that all of the wonderful progress above shown by the street railway interests cannot be directly attributable to electricity, as the introduction of cable in New York City is, to a certain extent, responsible for such progress, yet as the effect of the cable traction on our general proposition is so similar to that of electricity, and as New York is so fast becoming an electric traction city, it is considered unnecessary to go into the refinement of sub-division of mechanical traction methods in their effect, for both tend to demonstrate the theory which we have advanced, and show that as great benefits have been conferred upon the community served as can be done consistently with the financial investments, in the corporations, and, unquestionably, to a certain extent, show also that in development which discounts the future, resulting in the public benefit referred to, the interests of stockholders may not have been as thoroughly promoted as if a less liberal policy had been pursued. Yet, some of the figures, unless further explained might be grasped by those who advocate municipal ownership, reduced rates of fare, and additional burdens upon street railway corporations, as demonstrating the theories of increased earnings, reduced operating expenses and other things which they consider sufficient reasons for advocating the practical confiscation of vested rights of the greatest benefactors, in a corporate way, communities have ever had. True, street railway earnings have increased and operating expenses have decreased, and many other advantages have come to the street railway companies through the introduction of electricity, but for every dollar of actual net return which the investor in street railway securities has received in the Empire State, we do not hesitate to say that the municipalities and the general public have received at least $10 direct benefit, and that the general public has thus profited far more greatly from the advantages of rapid transit than have the investors who produced it.

Let us consider some of the figures quoted. In 1896, the operating street railways of New York State paid $1,164,820.40 in direct taxes—a good-sized percentage in itself on gross receipts, as will be noted. This, let it be remembered, does not include certain additional amounts paid by the holders of securities of lessor and other companies or certain percentage contributions, which, if calculated together, would compare favorably in amount with the demands for percentage payments made by some of the loudest advocates of such theories. A little calculation will also show that the street railway companies maintain about 9,000,000 square yards of street surface or paving; the practical equivalent of maintaining a street 250 miles long; yet, as is well known, with the now rare exception of horse railways, the street railways of New York State do not wear the surface of the street at all, but their tracks unquestionably save much wear from vehicle travel, as compared to the ordinary roadway, which must be maintained by the municipality. Remember these burdens are imposed for the privilege of running the "poor man's carriage."

From a calculation based upon the census returns of 1890, the average tax rates of the various cities in New York State, the owner of an ordinary carriage or vehicle pays, proportionately, only about one-sixth as much for his privilege of going where he will with the same and wearing out the pavements at pleasure.

One of the results, for which I presume electricity must be to a certain extent held responsible, owing to the expectation of greater returns and other excuses made by municipal officials, for unreasonable assessment, is inequality of taxation. To illustrate this point, the author has included a somewhat surprising calculation, compiled from the Railroad Commissioners' report for 1896, which would seem to demonstrate that valuation of property, earnings, passengers carried, car miles run, or no other intelligent basis of assessment of taxation on street railways in this State has been followed, and that certain hardships have resulted, is clearly apparent.

But to return to our analysis of the general statistics given, it is to be regretted that the data is not attainable which would show the exact increases in valuations of real estate, caused directly by the extensions of street railway lines during the past ten years. We believe, however, that such increases in New York State amount to $300,000,000, a direct gain to the holders of abutting and adjacent property and a direct benefit to the State and municipalities by increasing the amount of taxable property. This, it will be noted, is more than the entire investment in street railway properties.

Let us make another calculation: It is certainly reasonable to suppose that the extensions of street railway lines, and faster service obtained, during the past ten years, saves to each passenger at least ten minutes of time. This means annually to the citizens of New York State, a saving of 112,083,127 hours. Consider such time to be worth only an average of as low as 10 cents per hour, and we have a saving of $11,208,312, or nearly double the net earnings from the operation on all the street railways of the State.

Looking over our figures, we might be met with that oft-repeated statement that street railways have been overcapitalized. To this charge we cannot but reply that the promoters of some of the street railways have not been entirely guiltless of the sin of overcapitalization to a certain extent, yet far less than is ordinarily supposed. We believe, however, that the aggregate amount of all such illegitimate financiering in connection with the street railways of New York State, since the advent of mechanical traction is not so great as the unintelligent and wasteful expenditure of public funds in one or two large cities of the United States, for a fraction of this period, and we cheerfully invite the advocates of municipal ownership to devote some study to this feature. Where the money represented by the present investments has gone is in the legitimate purchase of underlying companies or companies antedating mechanical traction and in expensive construction and equipment, which could be duplicated to-day at a much smaller figure. Some illustrations of this feature. In the early days of electric traction, when most of the construction and equipment was done in this State, girder rails cost more than double their present figure; electric car equipments from 250 to 400 per cent. more; car bodies from 25 to 35 per cent. more; power station equipment from 100 to 300 per cent. more. That prices have depreciated is not the fault of the railway investors and managers, and surely does not affect the legitimacy of their investments. The public should feel grateful for the additional incentive which the present low prices now give the railway corporations for offering them still better transportation facilities. Somewhat on the same lines, we should refer to the mistaken impression generally prevailing, even among those who are supposed to have some knowledge of the subject, as regards the entire cost of thorough electric railway construction and equipment. As illustrating this, a few months since, I was called upon to prepare a careful estimate on cost of duplicating an extensive street railway system in the West, where the city engineer had stated that approximately $3,500,000 would rebuild the system in accordance with the most approved ideas. The engineer referred to was requested to answer a long list of questions, which practically constituted specifications, as to his ideas on construction and equipment, and a most careful calculation was made by myself and others in accordance with his ideas, the result being that at least $7,500,000 was found to be necessary to duplicate such a system in accordance with the specifications of such engineer. The opponents of the present methods of street railway ownership and operation would probably state that the rapid extension of street railway lines

would not have been made had not additional returns been expected by the investors, and that, to a certain extent at least, the results which we have quoted would verify this statement. Yet, far more apparent than this is the fact that with the extensions of lines have come the transfer system and lengthened routes, so that the average nickel will now carry a passenger three times as far on the street railways of New York than it would have done ten years ago; another illustration of the benefits which the public has derived, and it is safe to say we would hear no comments on the fact, that the rates per passenger had been reduced during the past ten years.

Let us now, for a moment, consider what might have been the result had the street railway management of New York State, as a whole, been less progressive than it has. All of the large systems are practically the outgrowths of old horse car companies, which were generally laid out on the principal thoroughfares, affording a large short haulage travel, and which could now be handled in a most profitable way by mechanical traction methods at an average rate much less than upon systems which have extended their lines, so that a large proportion of their mileage is suburban, or through comparatively unprofitable territory. Let us cite a case from actual records, showing what the effect would have been. A certain street railway system in a large city, operating about thirty miles of track by horse traction in 1887, equipped its lines with mechanical traction, but has never extended the same. It is well managed and gives magnificent service, but cannot be said to have conferred the benefits upon the community which other systems have that have followed the general programme of extension. The following shows the approximate results from its operation in 1887 and 1896:

	1887.	1896.
Gross receipts	$1,346,550.00	$2,680,448.00
Operating expenses	974,794.00	1,448,157.00
Per cent. operating expenses to gross receipts	72.5	54.2
Fixed charges	294,326.00	316,007.00
Net incomes	77,428.00	886,284.00
Dividends	60,000.00	800,000.00

We think no comment is necessary to illustrate this company's prosperity. Nor does it need any elaborate argument to show that in this particular case at least better results could not have been obtained had extensions been built.

We have heard it claimed that the employés of the street railway companies have not profited as they should through the advanced methods adopted by their companies. A glance at the statistics we have quoted illustrates how their number has increased and the following statement will, we think, demonstrate that the condition of the employés of no other large industry in this country has shown as comparatively great improvement in ten years as has that of the street railway employé in the Empire State.

COMPARATIVE STATEMENT OF AVERAGE WAGES AND SERVICES REQUIRED OF STREET RAILWAY EMPLOYEES OF NEW YORK STATE.

	1887.		1896.	
	Wages. Per hour.	Hours. Per day.	Wages. Per hour.	Hours. Per day.

We regret that time and space will not permit us to make an elaborate comparison of the wages paid street railway employés here with those prevailing abroad, or to demonstrate at length that electric traction increases the labor account, although it produces economy in other directions. We would note, however, that according to the last report of the Glasgow tramways—the model horse railway system of the world and the ideal of municipal ownership—that the total wages aggregate but 43 per cent. of the operating expenses, while on that model of electric street railways, the Buffalo (N. Y.) system, as shown by its report for 1896, over 77 per cent. of the entire operating expense is paid to labor, while this percentage holds practically good on all the street railways of the State operated by mechanical traction. This analyzed would mean that out of approximately $29,000,000 gross receipts received by the street railways of the State, $13,000,000 are paid directly to employés as wages, while, of course, a goodly share of the remainder of the operating expense goes indirectly to labor in the production of materials required in connection with operation and replacement. Against this, the stockholders of the operating companies get but, approximately, $3,400,000 annually in dividends for their large investment.

Now as to the most serious of all offenses that have been charged to mechanical traction, viz., accidents. The daily press is constantly filled with references to the "Deadly Trolley," with occasional remarks concerning Mr. Vreeland's cars of "Juggernaut," but what are the real facts concerning this very serious matter, and what are the comparative results between the present and the past on street railways in this State, and how does the annual result compare on street and steam railways. According to the Railroad Commissioners' report of 1896, there were killed on the street railways of New York State 13 passengers, 7 employés and 51 others, making a total of 71. This represents one for each 1,807,316 car miles run, or one for each 9,383,258 passengers carried. Against this number the surface steam railways killed 5 passengers, 211 employés and 544 others, or a total of 760. This represents one for each 241,950 train miles run, or one for each 235,941 passengers carried. So it is safe to say on fatalities that our steam railway friends are producing the same in the proportion of about eight to one, as against the street railways. In the same year the street railways injured 197 passengers, 35 employés and 157 others, or a total of 389. This represents one for each 329,875 car miles run, or one for each 1,728,788 passengers carried. During the same period the steam railways injured 174 passengers, 2,142 employés and 592 others, or a total of 2,908, running for each 63,233 train miles, or carrying 61,663. The total killed and injured on street railways was 462, or one for each 277,752 car miles run, or one for each 1,442,016 passengers carried. The total killed and injured on the steam railways amounted to 3,668, or one for each 50,131 train miles, or one for each 48,886 passengers carried. From this comparison it will be seen that if the daily press devoted as much space comparatively to steam railway accidents as to those on street railways they would have room for nothing else in their columns, and might require daily Sunday editions. To listen to some of the comments on street railway accidents, it would be supposed that no such thing had ever been heard of until the introduction of mechanical traction, yet in 1887 the street railways of New York killed one person for each 9,983,646 passengers carried; almost the same average as the present, as shown above. They injured one person for each 1,398,487 passengers carried, or proportionately 25 per cent. more than in 1896. This, we think, thoroughly demonstrates that mechanical traction is far safer than the horse car in every way. But another surprise. While, as shown, the percentage of accidents has been decreased, the natural inference would be that this improvement had occurred in connection with the passengers or employés, and that with increased speed must come greater danger to those upon the streets. Strange to say, however, the proportion of accidents between 1887 and 1896 to this class is 33⅓ per cent. less. It should be remembered in this connection also that the average speed of cars on the street railways of New York State has more than doubled during the past ten years.

The accumulation of statistics quoted has lengthened this paper far beyond my original expectations, until I fear it has became burdensome, and at the same time I may be accused of treating almost entirely subjects which would only indirectly come under the title, yet you are all practically as familiar as am I with the technical and engineering side of electric traction development, so I trust I may be pardoned for not dilating upon the same, and will close with the brief prophecy that another decade will find electric traction occupying the same position as regards operation of heavy standard railways that it now does toward the street railway.

MR. J. D. REID, who has so long been United States Consul at Dunfermline, Scotland, and has been one of the oldest officials in the consular service, will no longer hold that position, but is returning to this country on October 2.

THE CROCKER SAFETY SECTIONAL THIRD RAIL SYSTEM.

FOR some time past an experimental electric railway track has been in operation in the yards of the American Ordnance Company at Bridgeport, Conn., and on Aug. 23 a test of the system was made in the presence of a number of officials of the N. Y., N. H. & H. Railroad, including Col. Hefft, of the Consolidated Road.

The system is due to Mr. E. C. Crocker, electrical engineer of the American Ordnance Company, and its prime object is to render the exposed third rail harmless to persons and animals and to render short circuits, damaging to the station apparatus, impossible. To that end the third rail is divided

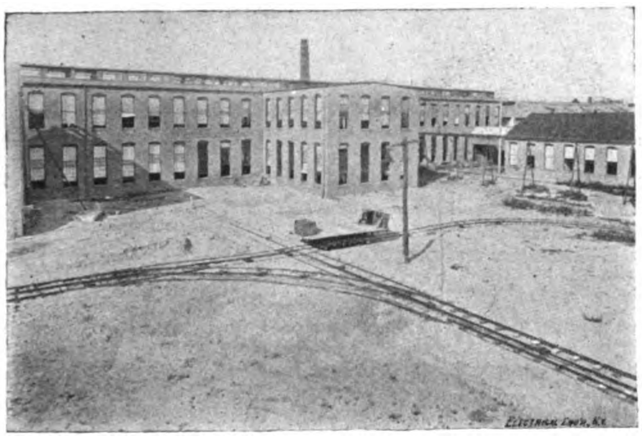

FIG. 1.—CROCKER SAFETY THIRD RAIL SYSTEM.

into sections, which are "alive" only during the passage of the car, being controlled by switches placed in boxes in the ground at short intervals.

The operation of the system will be made clear by reference to the accompanying engravings.

Referring to the diagram Fig. 2 S is the shoe carried by the car; 2, 2A and 2B represent the sectional third raials. 3 represents the feed wire. Fig. 4 shows a sketch of the way the third rail would be laid for street service.

If we start from the shoe S and trace back through magnet 1 it is evident, that magnet being energized by the current, it will draw the lever out of the contacts, the current passing on to magnet 2, energizing the magnets, drawing the lever into the contacts, passing through the contacts of the next box, which are closed from the fact that the car drawing current from the rail before has closed its contacts. The current then passes through magnet 4, drawing in the lever

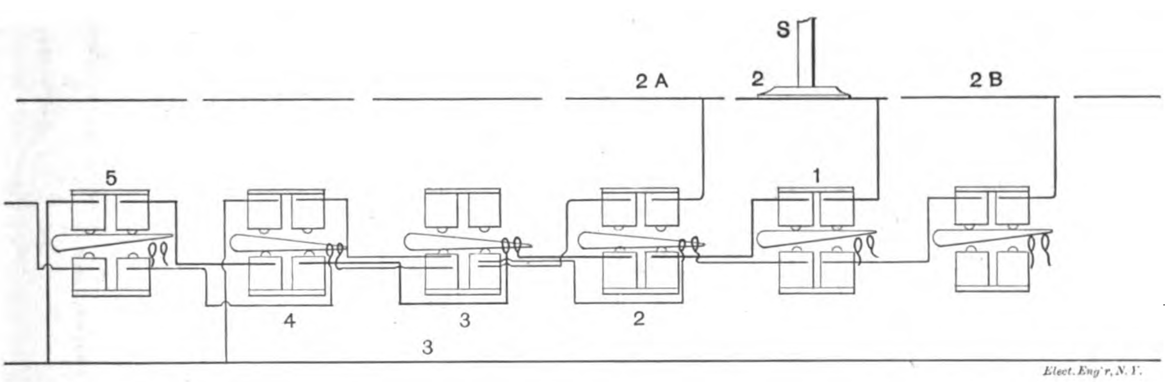

FIG. 2.—CROCKER SAFETY THIRD RAIL SYSTEM. DIAGRAM OF SWITCH OPERATION.

and closing the contacts; passing on to 5, drawing out the lever, opening the contacts and on to the feed wire.

It will become evident by tracing out the circuit that three sections are alive at a time. The current that the car draws cuts in the sections on either side of the section it draws from and cuts out the next preceding ones on either side, and repeats the operation as it goes along. By referring again to Fig. 2 it will be seen that when the shoe S passes on to 2B there will be an absolutely open circuit between 2A and feed wire 3; but if we go in the other direction and S passes on to 2A, then 2B will have an absolutely open circuit between the line wire and rail.

It will be evident that when power is shut off on the car and the car left running the car would slide over the line sections 2, 2A and 2B, and would leave them alive and hence the car could not start up again, as the section underneath would be dead. To eliminate this trouble an automatic switch is inserted with a resistance to use three amperes, so that when the controller is thrown around, shutting off the power from the motor, the automatic switch will drop, close the circuit with a resistance of three amperes, which is abundant to operate the magnets. Then when it is desired to start the motor again the current in the motor operates the automatic switch, cutting out the three ampere resistance, and allowing the motor current to operate the system. Of course it will be evident that in the winter time this automatic switch or the three ampere resistance will not be needed where heaters are used, as the current used in the latter will operate the magnet system.

The magnets are put in a cast iron box, enameled on the

FIG. 3.—THE MAGNET BOX.

inside and sealed so as to be water tight. The enamel prevents any sweating that might otherwise occur. The magnet boxes Fig. 3, are placed in the ground between the rails, over the top of which is run a conduit, into which the wires are run which lead out from the boxes. It will be evident by tracing out the circuit that there are four wires running between each box, which, with the feed wire, makes five.

Of course the third rail sections are made so that the car will cover the whole three sections at all times so as to make it impossible to get a shock from the system unless one gets underneath the car. The system installed at Bridgeport gives perfect satisfaction, nowithstanding that it is put in so exceedingly crudely that many who have seen it wonder how it is possible to operate it at all.

As to the cost of the system, it is estimated that it will reach anywhere from $5,000 to $10,000 per mile, depending on the place and number of boxes per mile. In some places, like steam or country roads, the cost will run as low as $4,000 per mile.

The design of magnets shown in Fig. 2 is not the design that will be put in for service, as the inventors have a method whereby the magnets, as soon as they have operated the switches and closed or opened the contacts, are cut out of circuit and the current goes through a shorter path, which eliminates all danger of the magnets burning out. It will be evident, too, from a study of the sketch, that there is no

possibility of the contacts in the boxes ever arcing or getting out of order, as the contacts, levers and magnets are all built rigidly on a bronze base. The reason that the contacts will not arc is that the circuit is never broken or closed in the boxes, as the section through which current is drawn closes and opens the contacts for sections where no current is

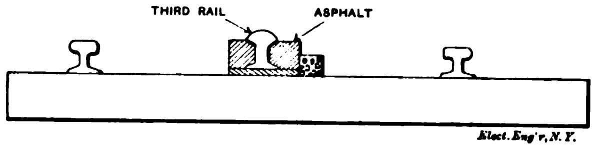

FIG. 4.—SECTION OF TRACK AND THIRD RAIL.

being drawn. The shoe used on the experimental track is a long, flat shoe, 24 x 4 inches, fastened in the middle of the car and held down by its own weight.

The track illustrated in Fig. 1 shows that the experimental installation embodies pretty nearly all the working conditions of practice, including as it does switches, curves, grades, crossovers and terminal facilities.

AMERICAN STREET RAILWAY CONVENTION HALL, NIAGARA FALLS.

As already announced by us, the convention of the American Street Railway Association will be held at Niagara Falls, Oct. 19-22. We are informed that the promised attendance will exceed that at any other convention in the association's history.

What will make the convention of particular interest to members is the exhibition of railroad apparatus to be made by the various manufacturers. This will be held in a special building recently arranged for the purpose, situated on Walnut avenue, midway between the two business sections of the city, and ten minutes' walk from the hotels.

The main floor, shown in plan in the accompanying diagram, Fig. 1, measures 132 x 132 feet. The front of the building, shown in Fig. 2, is two stories high and the upper floor is arranged for a convention hall capable of seating 300 people.

The floor plan shows the space and location of exhibitors. It will be noted that the whole floor has been spoken for and

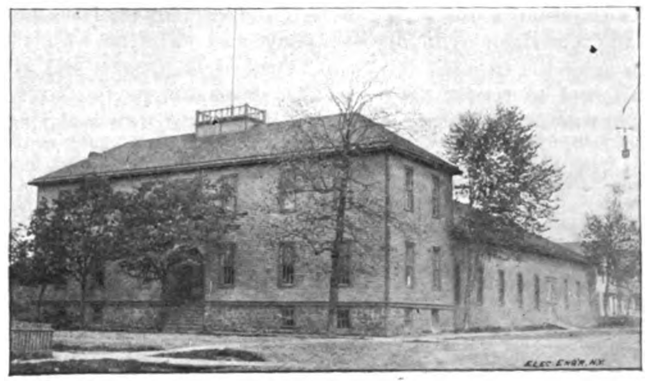

FIG. 2.-AMERICAN STREET RAILWAY ASSOCIATION EXPOSITION HALL.

we are informed that 5,000 feet additional could have been let had it been avaialable. This certainly speaks volumes for the interest taken in the coming meeting.

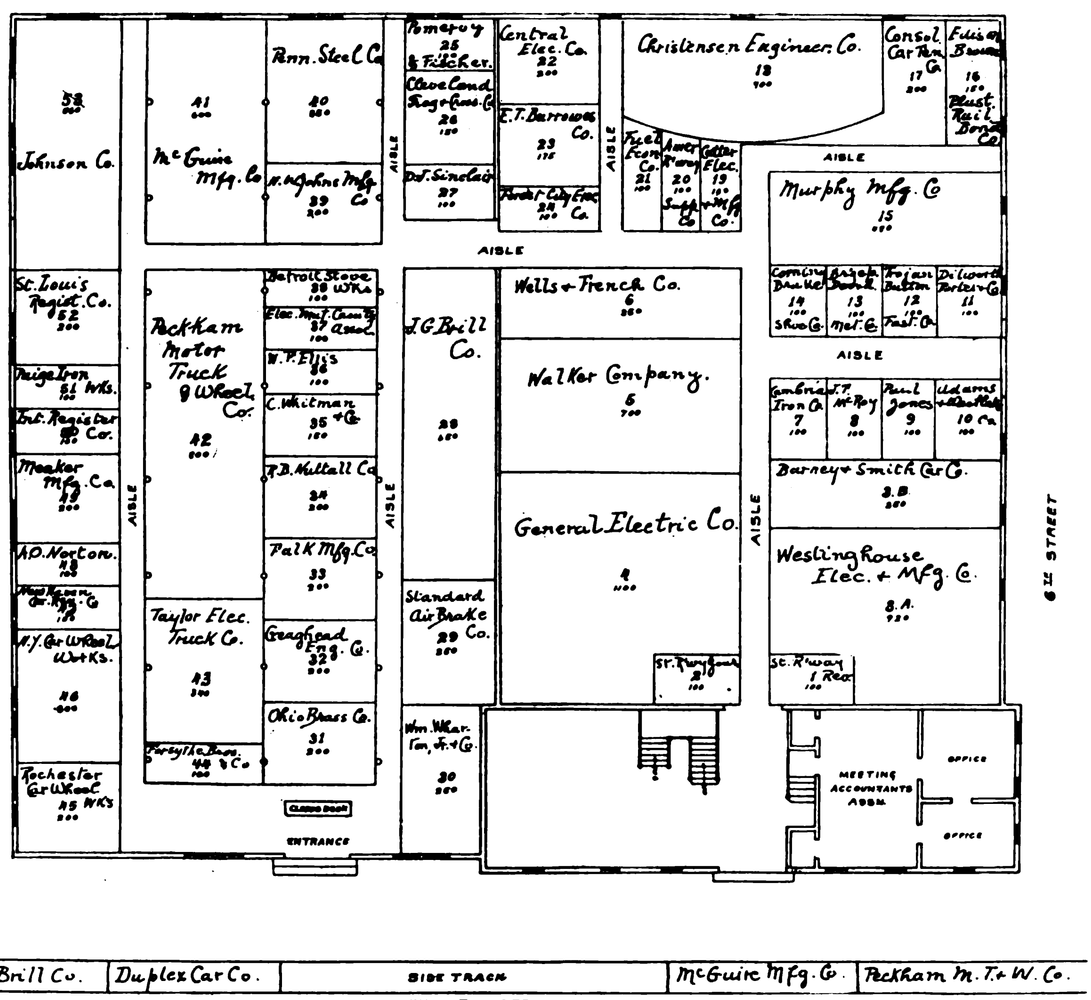

FIG. 1.—AMERICAN STREET RAILWAY ASSOCIATION.—FLOOR PLAN OF EXPOSITION HALL, NIAGARA FALLS.

We may add that the local street railway will run a branch to the hall for freight and passenger purposes, and a branch of the Erie Railroad will also run to the building.

THE JUNGFRAU ELECTRIC LOCOMOTIVE.

THE construction of the electric railway up the Jungfrau is being actively prosecuted, and it is expected that the first section of the road will be open for traffic by next season. All the constructive details have now nearly all been decided on and among the most important are the electric locomotives, which will depend for tractive effort on a rack rail, owing to the gradients which reach as high as 25 per cent.

The trains on this line are very heavy, on account of the endeavors of the management to combine great power with great economy. A train consists of one passenger car with motors on it, and one other car for either passengers or freight. Fig. 1 represents the cross-section, and Fig. 2 the longitudinal section of the car containing the motors and driving gear. The combination of the locomotive with a passenger car gives greater weight on the driving or braking wheels, and hence the cogs are less likely to rise out of the rack should the brakes be applied too suddenly. This arrangement also gives greater economy, in that the total weight of the train is reduced and its carrying capacity increased. The locomotive alone would have to weigh 12 tons, while the combined car as now to be constructed will only weigh 13 tons.

The carriage and the motor truck may be easily separated from each other in case repairs are necessary. The locomotive weight comes upon the two axles, seen in Fig. 2. The spiral springs shown are arranged to be not easily deflected, and their movement is limited to about 2-5 inch. The frame is built like the frame of an ordinary locomotive, and contains between the two supporting axles the two driving axles, on which are the cogwheels. Two electromotors, each of 125 h. p. at 800 revolutions, drive, by means of double reduction gearing, the main cogwheel. These reduction gears are duplicated on each motor, being arranged symmetrically on each side of the same.

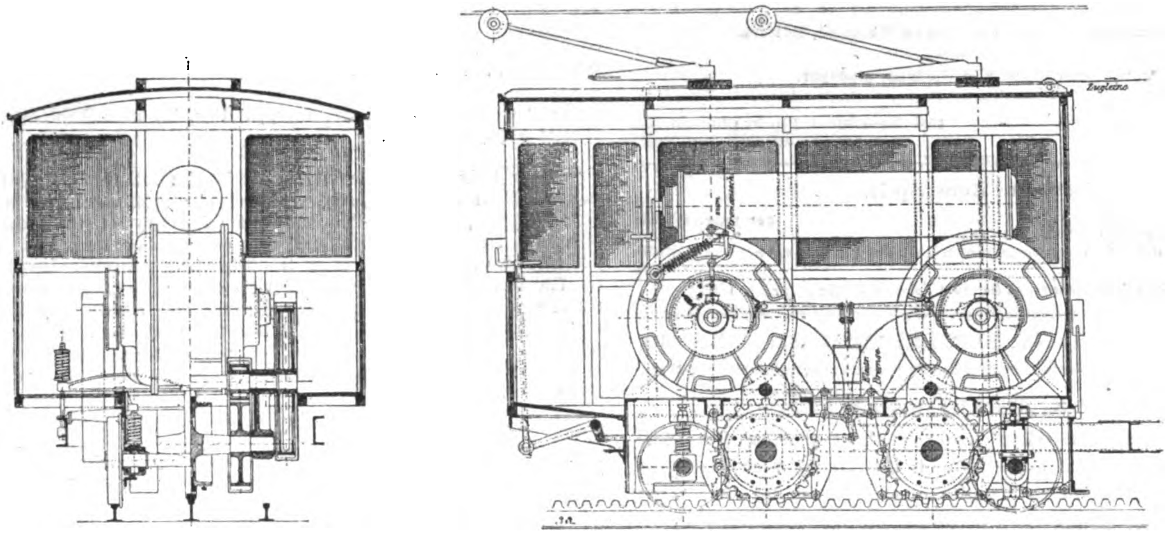
The highest output of these machines will be 300 h. p., corresponding to about 285 apparent kilowatts, or about 235 amperes per phase at a pressure of 500 volts. The pinions are made of aluminum bronze, the larger spur wheels of cast steel, and the driving cogwheels are made of cast steel which has also been wrought. The reduction gears have only a 1¾ inch pitch, and are machine-cut on the skew so as to secure an easy running and no side pressure. The driving cogwheels are made as large as possible in order to get a good grip of the teeth in the rack, and little wear from friction as possible. The driver's cab is enclosed, and is constructed of wood, on account of the cold. The locomotive has the following brakes:

1. An electric brake on the motor shaft, which is available as long as there is current passing through the motors. This brake is combined with the electric governor in this sense that the latter interrupts the current should an excessive speed obtain.

2. A hand-brake which acts by means of levers upon each of the brake blocks on the driving cog. The brake blocks are made of bronze.

3. The third set of brakes acts by gripping the rails. The engineer, as well as the conductor on the upper platform, may operate this brake. The gripping brake may also be used as a regulating brake when descending with the current interrupted.

The Jungfrau locomotive is the most powerful cogwheel locomotive which has been constructed so far. It has a tractive effort of 14,500 pounds. It will work on the three-phase system.



FIGS. 1 AND 2.—ELECTRIC RACK LOCOMOTIVE FOR THE JUNGFRAU RAILWAY, SWITZERLAND.

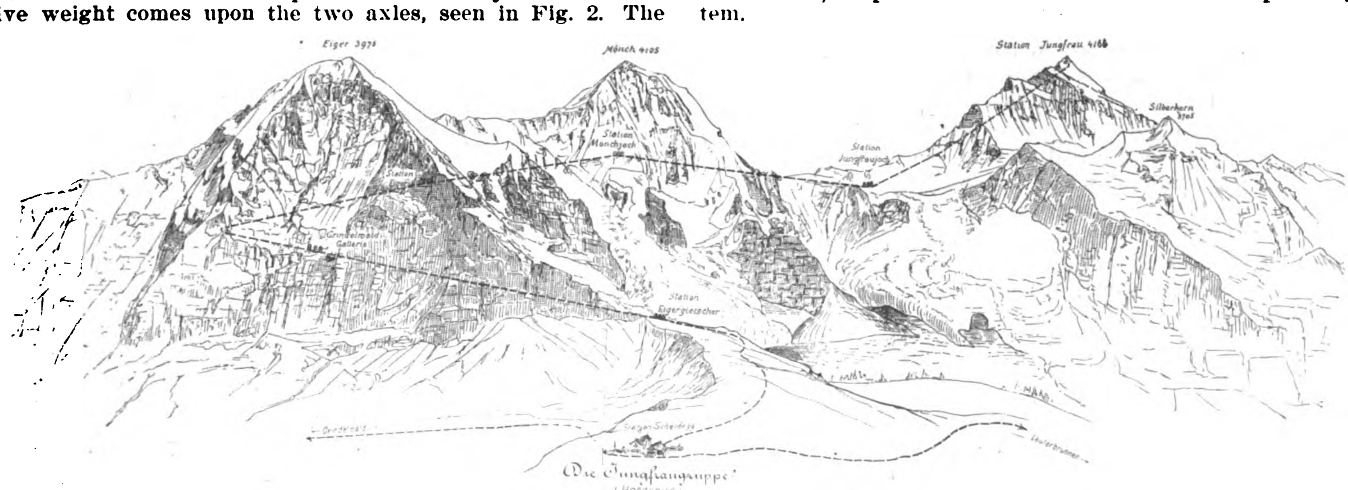


FIG. 3.—THE JUNGFRAU ELECTRIC RAILWAY. PERSPECTIVE VIEW OF ROUTE

The following are some of the principal data of the locomotive and road:

Gauge	1 metre
Maximum grade	25 per cent.
Diameter of driving gear	700 mm.
Number of drivers	2
Diameter of wheels	600 mm.
Speed	8½ km. per hour
Maximum pressure on gear teeth	6,500 kgm.
Speed of motor	800 r. p. m.
Weight of locomotive	13 tons

VOL. XXIV NEW YORK, SEPTEMBER 23, 1897. No. 490.

MUNICIPAL STREET RAILWAYS.

NEXT to "municipalizing" electric light plants, the idea most in favor with socialists of the Grout and Parsons type is that of "municipalizing" street railways; and they keep on quoting Glasgow as though instead of being one of the worst examples they could possibly cite, it was one of the best—a system which in private hands could be made to yield to the city many times the income and service that it now does under the glorified Bumbledom that is now being crowded upon us as the acme of perfected civilization. We are glad to note that President H. H. Vreeland, of the Metropolitan Traction Company, of New York, boldly and bravely met the issue at the Niagara Street Railway Convention in a very able paper on "Municipal Ownership." He said truly that the time had arrived for a clear understanding of what such ownership means, and his short but exhaustive argument penetrated to the very marrow of the subject. To be personal for a minute, we can readily imagine that a man who by sheer force of character and talent has lifted himself to such a conspicuous position would have many arguments in his mind, not set forth in his paper, against the disastrous modern tendency, if tendency it be, to reduce every large business to a government enterprise, with its deadening system of petty bureaucratic routine and régime.

Mr. Vreeland quotes in his paper the opinions of the courts, the opinions of leading authorities, and the anti-municipal views of the "municipalities" themselves. He states that it would cost the city of New York $295,000,000 to acquire the street railway properties alone; and as to the outrageously absurd statement that municipal ownership would cut the $42,000,000 of annual city taxes in two, he quotes Mr. E. E. Higgins to the effect that the net earnings of all the gas, electric light and street railway enterprises in this city is only $18,000,000 a year!

For his own company Mr. Vreeland, with commendable pride, puts forward a statistical table we cannot refrain from quoting. We only wish that water supply were in hands of a private concern, like this, and the matter of street paving and street cleaning also. Mr. Vreeland says:

"Nowhere in the debate on this subject have I been able to find, even in the statements of the most heated advocate of municipal ownership and operation, any denial of the fact that the centralizing under single management of the various railroads that make up the Metropolitan Street Railway system has improved the public comfort and convenience. The extent and nature of the benefits which this centralizing has achieved is best shown by the statistics. The following table shows the expansion of its transfer system for the last ten years:

Year.	Miles of Track.	Paying Passengers, Total Number.	Transfer Passengers, Total Number.	Transfer Passengers, Prop. to Paying.	Avr'ge Fare (Cents).
1896-97......	190	177,338,677	56,929,611	32*	3.78
1895-96......	172	145,965,251	28,450,996	19	4.18
1894-95......	140	109,686,472	9,671,697	9	4.59
1893-94......	131	107,036,524	5,306,654	5	4.76
1892-93......	80	63,011,785	3,203,832	5	4.76
1891-92......	61	45,259,670	2,645,800	6	4.72
1890-91......	37	39,971,929	2,766,080	7	4.68
1889-90......	36	39,571,464	2,523,239	6	4.70
1888-89......	36	37,386,809	2,206,866	6	4.72
1887-88......	36	37,318,730	1,996,871	5	4.75

*Years ending June 30, except 1887-88 and 1888-89, which ended September 30.

"From this table it will be noticed that in the first seven years about one passenger out of 15 or 20 received a transfer; in the year 1894-95, one out of every 11 passengers received a transfer; in 1895-96, one out of every 5; and in 1896-97, about one out of every 3. The phenomenal development by the company of this great privilege speaks for itself. By means of it, the general fare during the whole day has been reduced to 3.87 cents, and during the crowded, rush hours of morning and evening, when the working people are going to and coming from their work, the average rate of fare is only 2½ cents."

We venture to say that municipal street railways in New York would not do as much for the citizens in fifty years as Mr. Vreeland and his associates have done in five; and that Glasgow will grub along for a quarter of a century before it will be able to carry its citizens 25 miles for 5 cents, as Mr. Vreeland does without fuss or boast.

TELEPHONY IN NEWS TRANSMISSION.

WHATEVER may be the exact facts as to the new terms made between the American Bell and Western Union Companies, it would seem certain that another era has begun as to the transmission of news by telephone, something which the old contract frowned upon and forbade, although the prohibitory clause is said to have often been more honored in the breach than in the observance. A very striking instance of the new work being done is afforded by the recent telephonic transmission of intelligence from the Klondyke to San Francisco and New York. As a matter of fact, the telephone was in use only over a small part of the circuit to San Francisco; but that limitation aside, the work was remarkable in more ways than one. The news referred to had been sent to Mr. Hearst's two papers, the San Francisco "Examiner" and the New York "Journal," from St. Michael's by a staff correspondent. The matter had to be put on the wires on the arrival of the steamer at Puget Sound. From Port Townsend there to Olympia a circuit of 101 miles of telephone wire was available, and the newspaper representative at Port Townsend took the transmitter while a young lady at Olympia with a receiver to her ears, sat at a typewriter, the sheets from which were handed to a telegraph operator in circuit with San Francisco. Dictation began at 9:45 p. m., and was finished at 2:45 a. m., making just five hours, during which time 10,000 words are said to have been taken off with accuracy. The line was that of the Sunset Telephone Company, galvanized steel, running for about half the way through dense forest penetrable only by men when on foot. Of course, the work had been prearranged, and Mr. A. C. Sands, the company's superintendent of its first division, was present in person to supervise it at Olympia.

It will be remembered that there has been much discussion as to the capacity of a telephone line for transmission in bulk. So far as we are aware, this is the first authentic instance of the kind, and we are free to confess some slight disappointment as to the result. Mr. P. B. Delany has been asserting that the telephone and telegraph are on a par, and that, although one can easily talk and hear 120 words a minute intelligibly over the telephone, that is not the real test when it comes to the crucial point of recording. It will be seen that the speed made, over the 101 miles, between Port Townsend and Olympia, was 2,000 words per hour, or about 35 words per minute, if we allow for short interruptions and brief interrogations. It would be interesting to know just how much limitation of speed the use of the typewriting machine imposed. The speed made on that was not at all remarkable, but in

turn was obviously checked by the double strain imposed by the telephone on the young lady, Miss H. G. Hicks, of Tacoma, who received the long message. Are we to infer that 35 words is the limit when receiver and typewriter are thus used together? The question suggests many others, and opens up an interesting field of technical discussion and speculation.

ELECTRIC RAILWAY ADVANCES.

FEW men have been so actively connected with electric-railway exploitation in this country as Mr. W. J. Clark, whose paper on the advances of the decade is begun in our current issue. Merely to enumerate the roads that have been built, started, negotiated, laid out and reported on by that indefatigable and farsighted worker would fill columns of this journal; and it is to Mr. Clark's infinite credit that so little of his labor was done on wrong premises, or has not justified expectations. As his brilliant, yet solid, paper shows, he seeks data for all his results and for all his forecasts; and the picture he presents is one in which those who in various lines of electrical endeavor have toiled shoulder to shoulder with him can also contemplate with great satisfaction. Mr. Clark, it may be said, believes in the early beginning of a steam railway revolution equal to that which has seen the horse supplanted by the trolley; and we trust that ten years hence he may be able to stand up and enumerate the points in which electricity has again, on a larger scale even, benefited the great traveling public. Just at a time when social economists have been deploring the tendency of the population to crowd into narrow city limits, the trolley has set in motion enormous influences working in exactly the contrary direction, and sending great masses of the people out into the suburbs and the country to live. Mr. Clark's paper shows in detail this great fact, which we have summed up in a few words; and it is to be expected that the use of the trolley on steam lines, with smaller and more frequent trains, will aid in this desirable centrifugal movement of the population, by giving them homes of their own and a real stake in the real country.

THE FUTURE OF ELECTRICAL DISTRIBUTION.

IF as short a period as five years ago any member of the Edison Association had got up and advocated the use of the alternating current in any form he would probably have called down upon himself a shout of derision, and who knows but what something worse might have happened to him! The change of sentiment that has come over the electrical fraternity is well illustrated by the calmness and even approbation with which the association at its meeting last week listened to the advocacy of the alternating current as a transmission auxiliary to the three-wire direct current system of distribution in large cities.

Mr. Ferguson, of course, does not stand alone in his appreciation of the benefits to be derived from a judicious use of the high tension current, but the practical acquiescence in the arguments brought forward by him by the majority of the members present shows that chauvinism in electrical matters, as well as in politics, can only lead to retrogression, and that the station manager who would be up-to-date must choose wisely and without passion the means which the modern electrical arts place at his disposal.

What makes Mr. Ferguson's paper perhaps more striking is the fact that he practically discountenances the use of storage batteries as auxiliaries to distribution, in favor of the three-phase high tension distribution with local rotary converters. In this respect Mr. Ferguson's position differs from the stand taken by a number of the larger Eastern Edison companies, who have installed storage batteries to a considerable extent. Of course, no system of rotaries, whether high tension or not, can take the place of the battery as a storer of energy, nor do we, for a moment, imagine that Mr. Ferguson is of this opinion. The point he wishes to bring out evidently is that by means of high tension feeders with local rotary transformers all the generating units can be installed in a single station and there operated under the conditions of highest economy. Perhaps as good an example as the scheme which Mr. Ferguson advocates is that about to be put in operation by the Brooklyn Edison Company, and mentioned by Mr. Ferguson, where three-phase high tension current will be transmitted to various sub-stations and there converted into low tension for distribution on the three-wire system; but even in this instance storage batteries will ultimately in the majority of cases be installed in the local stations to take care of the local peaks, and periods of light load. We believe that Mr. Ferguson's thoughtful paper will have a marked influence on the extensions of the present Edison companies. But while they are now advocating high tension for transmission, one cannot fail to notice the strong allegiance of the old Edison man to the low tension direct current three-wire system as the system, par excellence, for distribution. One cannot help admitting that that system has certainly stood the test of time exceedingly well, and Mr. Ferguson was not too exuberant in his commendation of the system and its originator. There are, indeed, few examples afforded in the history of the arts in which a system has so long and so well served its purpose as has the Edison three-wire direct current system. Nevertheless, it is patent from Mr. Ferguson's paper, and from the work now going on in Edison stations, such as that in Brooklyn, that the old Edison engineers are both willing and able to keep up with the times, and to establish still further the supremacy of the low tension three-wire distribution by calling to its aid the powerful high tension allies now ready to their hands.

INDUSTRIAL PROPERTY CONVENTION.

TWO subjects of great importance came before the American Bar Association at its recent meeting in Cleveland. One, the arbitration treaty between this country and Great Britain, has been the subject of widespread popular interest and discussion; the other, the Convention for the Protection of Industrial Property, was passed almost wholly unnoticed, and yet if carried out in its spirit would remove in a large part the occasion for an arbitration treaty. By the Convention for the Protection of Industrial Property, concluded at Paris, March 20, 1883, and now existing between the United States, Great Britain, France, Belgium, Italy, Spain, Portugal, Holland, Norway and Sweden, Denmark, Servia, Switzerland and Brazil, rights arising from invention or from the reputation gained in trade are regulated and protected. In the case of invention, the favorable policy of this government as to publicity before patenting is extended to European nations, members of the convention, where the rule of secrecy before patenting prevails. Under the convention, a period of time, after the first application, is allowed, in which the acts which usually invalidate a patent, will be ineffective, viz., the publication of a description of the invention, its use, sale or exhibition. This period, which is seven months, is called a period of priority. The theory is that the applications made in all the countries during such period are made on the same day, i. e., on the day of the filing of the first application, and, therefore, that the invention is still secret at the time of the application. It results from the convention that the invention can be freely offered for sale for a period of seven months after the application in one of the countries of the Union, and still be the subject of a valid patent if the same is applied for within the period of delay. This gives an opportunity to our inventors to sell their intellectual productions without the necessity of prior patenting in the countries adhering to the convention. If all of our inventions, patented here, were sold abroad for but $100 each, they would bring into the country a vast sum each year. Trade-marks and commercial names are also provided for in the convention. In no class of merchandise is reputation more valuable than in that of electrical devices. The trade-marks and commercial names connected with these goods are worthy of the added protection which the convention gives. Under the convention, goods bearing false indications of origin are seized at the ports of entry or in the interior, in those countries which permit seizure, and in other countries the importation of articles so marked is forbidden. We are sorry to say that while Congress provided in the Dingley bill for the exclusion of articles bearing the trademarks of our manufacturers, those of manufacturers of other countries adhering to the convention were not noticed. This omission will, we hope, be corrected at the next meeting of Congress.

ECONOMY OF AMERICAN INCANDESCENT LAMPS.

WE print on another page a communication from a well known lamp manufacturer, in which the writer shows in a very clear manner just what degree of efficiency American incandescent lamps have attained. The communication is apropos to a note which appeared in a recent issue of The Engineer, calling attention to the new Maxim mineral filament lamp for which high efficiency is claimed. In the original dispatch containing the announcement the economy of American lamps was stated at a very low figure, so low, indeed, that we exonerated Mr. Maxim from all blame on this score. But it is just as well to have it distinctly shown just what can be done in lamp manufacture on this side of the water and Mr. Rhotehamel's communication will, therefore, be read with interest.

ELECTRIC LIGHTING

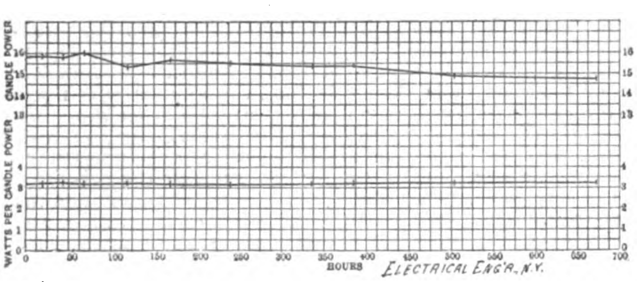
THE NEW MAXIM LAMP AND AMERICAN INCANDESCENT LAMPS COMPARED.

BY J. H. RHOTEHAMEL.

I HAVE noticed the Engineer's editorial on Maxim's new incandescent lamp in the issue of Sept. 2. I had also read the dispatch by Mr. Frank M. White, which has now been pretty generally published in all of the papers of the country.

The statement in the dispatch in regard to the economy of American lamps is in error. The best quality of American lamps average between 3.1 and 3 1-2 watts to the candle. It is stated in the dispatch that the American lamps run 4.8 to 5 watts to the candle. It is also stated that European lamps take 4.2 watts to the candle. The lamp of Mr. Maxim is reported to be a 40 c. p. lamp (voltage not stated), and taking 2.8 watts to the candle. In high candle power lamps one can readily get higher economy than when one makes lamps at 8, 10 and 16 candle power and an 8, 10 or 16 candle power lamp at 3.1 watts is, in fact, a showing of higher economy than forty candle power 2.8 watt lamps considering the relative amount of light furnished. When one attempts to get high economy in very low candle power one cannot succeed so well as if dealing with very high candle power.

The incandescent lamp is not generally understood, owing to the fact that the general public are not familiar with its qualities. The type of lamp manufactured in the United States for several years, and in fact until about three years ago, was of a type such that while starting at a high economy, the filaments increased in resistance to such an extent that the light



TEST OF COLUMBIA INCANDESCENT LAMP.

fell off so much that they soon became lamps of low economy. The lamps manufactured by the writer's company during the past three years possessed the following qualities: The resistance of the filaments from the beginning of its time of burning throughout the entire life of the lamp is almost absolutely maintained. This result brings naturally with it a maintenance of candle power. If the filaments increase in resistance it follows that the light also must decrease. We believe the present filament manufactured by us is superior to any yet attempted and that Maxim's filament, with all that is claimed for it, is not its equal.

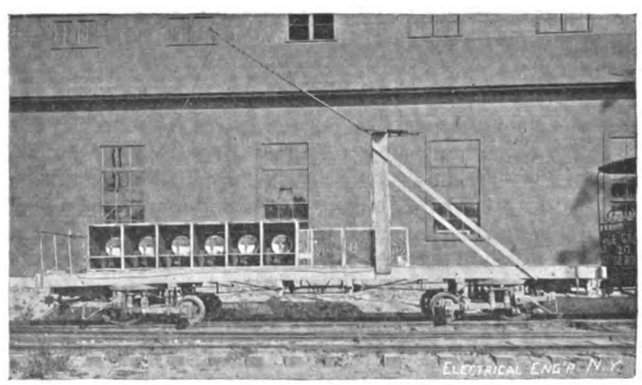
In view of sustaining our claims, I submit a diagram of a test made on lamps made from the filaments of which I speak, which shows the remarkable results outlined therein, and also proves that by the process employed by us in the manufacture of our new cellulose filaments we have obtained a material that practically maintains its resistance and gives a bright light throughout its life. We have already excelled the Maxim lamp in the fact that it is applied to a commercial product in all of the lower candle powers which are required for the purpose of economical illumination.

In reference to the cost of the mineral filament referred to in your editorial we do not think that the estimated cost by you would much exceed the cost of the present type of filament, but we very much doubt if a material from mineral can be made that will produce uniform results; that is, to undertake the manufacture of a certain type of lamp, say a 3.1 watt 110 volt lamp—can you produce filaments from a mineral substance that will give such results as to enable the manufacturer to make lamps that would be marketable in range of voltages? In the old types of lamps formerly produced it will be recalled there was a very great range of voltages. In the present types made by us we are able to guarantee almost absolute uniformity.

I think that the American manufacturer should be treated fairly in this matter and should not be misled by statements in regard to Maxim's lamp that are not correct, and your article does not seem to give any consideration to the quality of the American product in comparison with what Maxim claims. The result of this comparison would show that Maxim has, on the claims made, made no improvement over the American product, assuming that the statement of his correspondent is correct in regard to the quality of the lamp which he claims to have produced.

ILLUMINATING THE NIAGARA WHIRLPOOL RAPIDS.

IN The Electrical Engineer of Sept. 9, a very full account was given of the experiments carried out under the plans and direction of Mr. Luther Stieringer for the electrical illumination of the Niagara Whirlpool Rapids. We are now able to illustrate in the accompanying engraving the simple apparatus used. It consisted, as noted already, of six ordinary G. E. search lights set in plain wooden boxes, painted black inside, with a polished silvered reflector at the back of each. These were put in a bank, with a rheostat, and a switch for letting in the trolley current, and all mounted on a mere flat car. Along the front of the lamps were slid colored mica or gelatine screens, and thus beautiful and weird effects were obtained; the flat car being towed a few yards in front of the cars with passengers. The effects were so unique and so good, an extension and development of the scheme may be expected, and Mr. Stieringer is said to be now working upon the details with his usual thought and originality. Crude as the apparatus was, indications enough were given of the possibilities, and hereafter visitors to the Falls will want to take the Gorge trip by night as well as by day. Mr. S. D. Greene thinks he can arrange for a repetition on a larger and finer scale at the time of the national street railway convention next month.



ELECTRIC PROJECTOR CAR FOR LIGHTING WHIRLPOOL RAPIDS, NIAGARA FALLS.

The lamps will be put higher on the flat car so as to get a range for their beam from one bank to the other, and by means of lamps with a flatter beam, it is expected to illuminate as much as 300 or 400 feet of the "Atlantic in a spasm," at a time. And if this is successful, something will probably be done to make the Falls themselves visible at night, and to fit them up with displays on nights when the lunar rainbows are not due. At night the Falls are now only a voice, and there are rarely any public amusements in town; whereas hereafter by night as well as by day, Niagara will become the greatest show on earth.

THE TACOMA MUNICIPAL PLANT.

At Tacoma, Wash., the special council committee appointed to investigate the conduct of the light plant has made its report to the council. The committee found the plant in a very uneconomical condition. The engines and boilers and auxiliary apparatus were old-fashioned and uneconomical. It will cost about $40,000 to reconstruct the plant, so that it can be economically operated. In the month of May the committee states electricity produced at the city plants cost 2.76 cents per k. w. hour, or a total for the month of $1,752. The same amount of electricity at the rate paid for current now purchased under contract would have cost the city $952. Or, in other words, if the city had purchased its electricity at the rate paid for the day load it would have saved in May $800. This would amount to a saving of $9,600 a year.

ECONOMY IN DISTRIBUTION OF ELECTRICAL ENERGY.[1]

BY LOUIS A. FERGUSON.

EVER since the advent of the Edison Central Station for the distribution of electrical energy for lighting and power work, it has been the universal practice among the designing engineers of both the parent company and the local companies, to confine themselves almost exclusively to the use of the direct current for both transmission and distribution.

Following this idea it has been customary in the development of the lighting and power business of a large city, to erect the original central station in the heart of the business district, laying an Edison underground net work in that section and supplying it by feeders from the station.

With the successful lighting of the business district a demand is created for the electric light in the residence portion of the city, and to supply this the same method is followed as has been employed in the down-town district. Another steam plant must be erected at a central point and the territory covered by a net work of underground conductors. Other districts are covered in the same way until three, four and sometimes five steam stations are generating and supplying electricity to the several portions of the city; in some cases, each supplying its own respective district, and in others, all stations delivering energy into one general net work of conductors, covering the whole territory. It has been the practice in some cities to connect the bus bars of two or more stations by means of direct current tie lines; in some cases the tie lines being used to send current from one station to the other to assist at the time of maximum loau, or to charge storage batteries, or even to furnish the entire output during hours of minimum load in the territory supplied at other hours by a generating station.

In all cities of moderate size or considerable importance the service is furnished twenty-four hours every day in the year, therefore the cost per kilowatt hour of operating in the stations having a small load factor will be very high, especially during the hours of minimum load, which is often sixteen or eighteen hours each day. This has been realized for some time and many methods have been suggested and employed to reduce the cost of operating the smaller stations in the large cities.

We have all listened to the arguments in favor of the use of storage batteries in conjunction with the steam plant in these secondary stations and several companies have employed them. Some of us are using the direct current tie line from the main station to the secondary station to supply the entire output for the secondary territory during the greater portion of the day, operating the secondary stations as a steam plant from dusk until midnight only.

In Boston a storage battery sub-station supplies the residence portion, the battery being charged from the net work during the time of minimum load, and in that city also a tie line connects the main station in Atlantic avenue, with the Head Place Station, charging a battery in the latter station and also feeding the underground system. The direct current tie line is economical and useful for carrying during the minimum hours, the entire output of a residence district station, or other station, having a small load factor, when the distance between the two stations is not so great that the loss of energy in transmission and the interest and depreciation on the cost of the tie line will counterbalance the saving effected by shutting down the residence district station, but when the length of the direct current tie line is very long it then becomes uneconomical, owing to the excessive loss of energy in transmission. The pressure curve of a tie line fed sub-station whose underground net work is not interconnected with the net work supplied by the main station, will be a very bad one, owing to the fluctuations of pressure due to ordinary variations in load, and more especially so if the load on the sub-station be even slightly unbalanced, which condition causes an excessive drop on the neutral of the tie line.

If, however, the underground net work of the main station and the sub-station be interconnected and the tie line between the station bus bars be used only to take such a portion of the sub-station output as will be necessary to give the desired pressure at the sub-station bus bar, then the pressure curve of the sub-station will, without doubt, equal in regularity that of the main station and the use of the tie line under this method will be economical and satisfactory.

While direct current tie lines between stations over two miles apart are useful at times of maximum load and in cases of emergency, this method is not the most economical for shutting down the sub-station under the ordinary conditions existing in large cities, even when storage batteries are employed in the sub-station.

It has been my belief, for several years, that the day has passed when we should erect steam generating stations distributed in the various sections of our large cities, and I feel confident that the greatest and most profitable development in the lighting and power industry will be effected by intelligent combination of the alternating and the direct current, the former being used for transmission and the latter for distribution. I think it is generally conceded by all fair minded engineers in America, experienced in central station work, that despite all the advance in alternating current work in recent years, there has not yet been devised a system of alternating current distribution which possesses the advantages and simplicity of the three-wire direct current system for cities of moderate or large size. This being true, the underground system will remain as it is and any increase in economy of operation must come from the abandonment of steam generating stations, except one, or possibly two main stations located on the water front where multiple expansion condensing engines can be employed and cheap fuel may be obtained. The supplying of the business district will be from the main station by means of the three-wire direct current system if the distance from the station to the electrical center of distribution be less than, say, one mile. The remaining two, three or more stations, as the case may be, which formerly supplied the outlying territory will be abandoned as steam generating plants and will become simply sub-stations, receiving their electrical energy from the main station by means of three-phase alternating current transmission.

Under conditions where the main station is within a mile of the electrical center of the business district and the principal output is furnished by the three-wire system, there will be three methods of supplying the sub-stations, the apparatus in the sub-stations remaining the same in each case:

First:—In the main station we may install three-phase alternating current generators in suitable units to meet the conditions, the combined capacity being sufficient to take care of the entire output of all of the sub-stations. These generators should be built with rotating field and stationary armature and wound for the voltage of the line transmission, which should be from 2,000 to 6,000 volts.

In each sub-station there should be stationary transformers wound to reduce the pressure from that of the line to about 80 volts. The secondaries of these transformers in sets of three should then be connected to rotary current transformers in units of proper size to suit the conditions of the load in the sub-stations. The rotaries should be arranged in pairs, each rotary having an independent set of stationary transformers, and having the direct current side connected to the bus bars of sub-stations on three-wire plan. They will take the alternating current from the line, convert it to direct current at from 115 to 130 volts and deliver it to the bus bars for distribution, giving to the customer direct current as formerly supplied by the Edison dynamos. This method is an exceedingly efficient one and assuming that the efficiency of the alternating current generators in the main station is equal to that of the original Edison dynamos in sub-stations, which is very conservative, then the efficiency of the system from the switchboard in the main station to the switchboard in the sub-station will be from 84 to 86 per cent., based upon the following efficiency in apparatus; rotary transformers 91 per cent., stationary transformers 97½ per cent., line loss 3 to 5 per cent.

The Edison Electric Illuminating Company, of Brooklyn, has adopted this method of distribution for development of new outlying territory, and is now installing apparatus on a large scale.

The second method, which though apparently not as efficient as that just described, when the apparatus is considered by itself under full load, will be found exceedingly useful in developing new territory and for additions to existing plant and may yet, when all things are considered, prove nearly as efficient as the first method.

Instead of installing in the main station three-phase alternating current generators for the express purpose of delivering energy to the sub-stations, we may install in the main stations rotary current transformers so wound that their direct current sides may be connected to the positive and negative bus bars of the main station, and operating conversely to the manner of operating rotaries in the sub-station. They will then take direct current from the main station bus bars, convert it to three-phase alternating and send it through stationary step up transformers which will raise the pressure to the desired voltage required for line transmission. The apparatus in the substation will be exactly the same as that described in the first method. With this second method we have the advantage of only one kind of generating apparatus in the main station, all direct current on the three-wire plan, and further, all current required by the converse rotary to supply the sub-station trans-

[1]Read before the Assoc. of Edison Ill. Co.'s, Niagara Falls. Abstract.

mission will be obtained from the Edison generators in the main station, thus loading them and their engines and increasing their efficiency of operation. This method is being employed by the Chicago Edison Company temporarily, although the apparatus was originally built for the third method, which I am about to describe, and which will ultimately be adopted by that company for all its sub-station work. The apparent efficiency of the second method is 75 per cent. considering the losses in apparatus and line by themselves and not crediting the advantages gained by additional loading of engines and dynamos in the main station.

The third method combines all the advantages of the first and second methods and has none of their disadvantages. The main station in this case is the same as before, having dynamos operated on the three-wire system.

Instead of the three-phase generator, as mentioned in the first method, we will install generators designed and built to give three-phase alternating current, and direct current at the same time in any quantities desired, up to the capacity of the machines. These generators will be practically power driven rotary current transformers and may be directly coupled to the engine, or belted if preferred. They will furnish three-phase alternating current to the sub-station transmission line through step up transformers in quantities sufficient to operate the sub-station, and the balance of their output may be furnished at the same time in direct current to the three-wire bus bars of the main station. As the demand at the sub-station increases the quantity of alternating current delivered by the special generators will increase and the quantity of direct current furnished to the bus bars will decrease correspondingly until finally when the time of maximum load has been reached in the sub-station the generators will be working at their full capacity as three-phase alternators and will be disconnected from the direct current bus bars.

The efficiency of this method from the main station switchboard to sub-station switchboard is from 82 to 84 per cent., considering all stationary and rotary transformer losses and line losses.

It will be seen, too, that with these special generators we have the advantage of working them and their engines at full load all the time, and, therefore, at maximum efficiency, and we also have the additional important advantage of avoiding duplication in machinery and being enabled to use the same investment in machinery for the maximum load, both in the main station and sub-station, when the maximum loads do not coincide, which is the condition ordinarily met with in America.

In many of these sub-stations it may be found advantageous to operate series arc dynamos for municipal or commercial lighting in territory not covered by the Edison net work, and in this case the rotary current transformer becomes an exceedingly useful machine. The shaft of the rotary may be provided with a pulley and belted to a pair of arc dynamos in tandem or to a line shaft to which are belted the arc dynamos to be driven. The rotary may then be used as a convertor of alternating current to direct current, and at the same time as a motor driving the arc dynamos. In this way its capacity may be utilized advantageously and the machine operated at good efficiency.

The rotary current transformer is exceedingly useful in developing new territory, since the machines are very small for their output, and a rotary sub-station will thus require only one-third the space of a steam station of the same capacity, and moreover the investment will be less.

Compared in point of economy of operation with a direct current tie line sub-station, or a storage battery sub-station fed by a direct current tie line, the rotary current transformer sub-station is much more efficient and requires less investment for the same output when the average peak width of the sub-station is over three hours, as is the case in nearly all of our American stations.

We have seen that the efficiency of the various rotary transformer methods range from 74 to 85 per cent., and experience in the operation of storage battery sub-station shows the watt loss through the battery itself to be 25 per cent. In addition to this we must consider the energy required to operate the booster for charging the battery, and also the loss of energy in the tie line between the stations. The labor required to operate the rotary current transformer sub-station is very small, only dynamo tenders being required.

Compared with the ordinary steam station in the residence district the economy of operation of the rotary transformer stations is very pronounced; two-thirds of the cost of fuel in the steam station, and all labor and supplies incident to the operation of the boilers and engines may be saved, and during sixteen or eighteen hours each day the sub-station may be operated with only one man, and without any additional labor in the main station.

In connection with the rotary current transformers in the sub-station, storage batteries may be employed, if desired, to be used as auxiliaries in cases of emergency, but they will not increase the efficiency of the system.

Appreciating the value of broadening the load curve of their low tension stations, a few of the companies have taken up contract arc lighting, both for commercial and municipal service with the result that several of the residence stations which formerly had an average peak width of two to three hours, now enjoy a peak from five to seven hours in width. This tendency to widen the peak width lessens the value of the storage battery in residence stations, owing to its great cost, and increases the value of the rotary transformer method for sub-station work.

The real field for the storage battery as an economizer is in its employment in conjunction with the main steam generating station, erected in the station itself when the latter is located in the electrical center of the district, and at the center of distribution when the main generating station is situated at a point distant from the electrical center of the territory to be supplied. The rotary current transformer methods, besides being more efficient in themselves, when compared with other systems, increase the economy of the main station by loading the units in that station in a manner similar to the storage battery.

The field for economy in the manufacture and distribution of electrical energy has not yet been exhausted, and there remains much that may be accomplished in electrical as well as steam engineering, but the best results cannot always be obtained by adhering to old methods and barring from our doors the experience gained by those who have been thinking along different lines than ourselves.

We must acknowledge the good to be derived from the use of the alternating as well as the direct current, when properly applied, and we should so employ them that we may enjoy the benefit of the advantages of both without the disadvantages of either, and thus devise for ourselves a system of generation and distribution which will be more efficient and more flexible in operation than any method which lies within the reach of the alternating or direct current alone.

ON THE PHENOMENON OF THE ELECTRIC ARC.[1]

BY ANDRE BLONDEL.

It is well known that there is a very large difference of potential, amounting as a general rule to at least 25 volts, between the two carbons of an electric arc. This difference of potential, u, increases somewhat rapidly as the arc lengthens, following the nearly straight law first enunciated by Edlund in 1867 [(1)... $u = a + bl$] to which Mrs. Ayrton has lately given a more accurate and satisfactory shape. The greater part of the fall of potential takes place at the passage from the positive crater, at least so far as we can make out by measuring the potential difference between the positive carbon and a carbon rod plunged into the arc close to the surface of the crater. There are two possible explanations of this great difference of potential between the carbons.

First Hypothesis.—The current encounters a high resistance, especially as it passes from the solid to the gaseous carbon; hence, the great fall of potential. Thermo-electro phenomena, if there be any, are negligible as compared with the potential difference we are concerned with, so that the arc, whatever its exact nature, is "equivalent" to a simple resistance.

Second Hypothesis.—The arc is the seat of a very big counter electromotive force, almost independent of the current, and due either to a thermo-electric effect at the contact of the carbons and the arc or to a polarization of the electrodes. This is tantamount to an assumption that the arc is an electrolytic phenomenon in which, for instance, incandescent oxide of carbon is electrolyzed. The resistance of the arc proper has but little to do with the effect under discussion.

After detailing a series of experiments made to test these theories the author concludes as follows:

It seems to me that these experiments definitely show that the electric arc behaves sensibly, like a resistance, and possesses, in the ordinary acceptation of the term, no counter electromotive force comparable to the observed difference of potential; it is not due, therefore, to an electrolytic phenomenon. With the accuracy obtained we may assert that if there be a residual electromotive force, due to thermo-electric causes, for example, it cannot exceed a fraction of a volt.

[1]Abstract, Journ. de Phys.

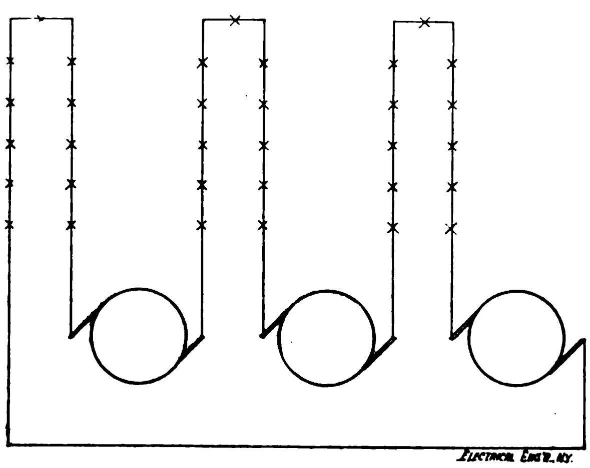
LETTERS TO THE EDITOR

ARC DYNAMOS FEEDING INDEPENDENT CIRCUITS.

Referring to the editorial, "The Future Arc Dynamo," in your issue of July 15, you state that "there are various situations in which 100 arc lamps are distributed on such classes of work that they are operated better on independent circuits. To enable arc machines of large capacity to fulfill this requisite has been the point kept in view in the latest constructions, one result of which is the most recent type of the Brush machine."

From the above it would seem that you considered the Brush machine capable of supplying several independent circuits, but it is not. The Brush machine of to-day is exactly the same in principle and operation as the old Brush machines of fifteen years ago. The latest type machine has three commutators, as before, all working in a single series, but instead of having all the commutators in one group and all the lamps in another group, as is the practice in most stations using the new machines, the lamps may be divided in three groups alternately with the commutators, as shown by enclosed diagram.

With this arrangement on a 150 light machine it is possible to run three circuits on which the voltage will normally not exceed 2,500 volts each, but if the circuit is accidentally



broken, or if the machine flashes, as it frequently does, the lamps all drop their carbons and the whole voltage of three 2,500 volt circuits, or 7,500 volts, to which is added the heavy discharge of the field coils, is piled up in a single discharge and at such times the strain on insulation and risk of life is fully as great as if the machine were supplying a single circuit of 150 lamps.

It is evident that the Brush arrangement of operating a number of circuits in series to keep down the voltage, when things are running normally, cannot be safely used for capacities any greater than for an equivalent capacity on a single unit, for arc machines will flash and circuits will be broken, and with a machine operating 500 lamps the discharge of 25,000 or 30,000 volts would break down any insulation that could be devised and it would require a splendid nerve to handle such a machine.

In my multi-circuit machine, which was described in the same issue, the circuits are all practically in parallel and the maximum voltage that can be obtained in any way is little higher than that required to operate a single circuit, and it is impossible to connect the circuits in series. It is entirely different from the Brush machine and the two should not be considered in the same class.

The interruption of one circuit, or the flashing of one commutator of the Brush machine, puts out the lights on all the circuits, as they are all in series. With my machine each circuit is as entirely independent, as if supplied from separate machines. SAM'L W. RUSHMORE.

THE LIFE OF WEATHER PROOF WIRE.

How many years is considered the lifetime or wearing time with absolute safety of No. 8 weather-proof wire, such as is used by the Heissler or other direct current systems for street wiring? O. B.

(Perhaps some of our central station readers will be glad to furnish one of their confreres with the desired information. —Eds. E. E.)

ROENTGEN RAYS

X-RAY DISCHARGES.

Jean Perrin, who has already done much to unravel the complex phenomena of the discharge of electrified bodies by Röntgen rays, has recently[1] made some decisive experiments with regard to the "effet metal," which is concerned in the discharge in addition to the better known "effet gaz." The latter as he showed before, is due to the ionisation of the gas traversed by the rays, and is proportional to the pressure, but independent of the temperature. As regards the metallic effect, it may be separated from the gas effect by a simple contrivance. A beam of X-rays is sent through between two plates of a condenser without touching them. A small piece is cut out of one of the condenser plates and is connected with an electrometer, while the remainder of the plate forms a kind of guard ring. The electrometer then indicates nothing but the gas effect. The same beam is allowed to impinge upon another condenser normally to the plates, and passes through an aluminum window on the second plate. In doing so it traverses a certain thickness of gas, which is made equal to the breadth of the small plate in the first condenser. This insures the identity of the gas effects in the two condensers. In addition, a metallic effect is produced in the second condenser, owing to the impact of the rays upon the second plate. By addition and subtraction the two effects may be separated. In this way it may be shown that the metallic effect disappears when the metallic surface is covered with petroleum, alcohol or water. When the metallic surface is clean the surface ionisation is constant for a given strength of source, distance, metal and gas. It varies inversely as the square of the distance. The constant depending upon the metal and the gas is analogous to surface tension or contact e. m. f., and is called the coefficient of surface ionisation. A definition of the strength of X-rays might be based upon this, but it is better to base it upon the gas effect, and to call unit quantity of X-rays that quantity which in air under 76 cm. pressure liberates in a spherical shell 1 cm. thick, with its center at the source, one electrostatic unit of positive electricity.

DISCHARGE OF CATHODE RAYS.

A fundamental difference between cathode rays and X-rays has been considered to lie in their manner of discharging electrified bodies. Whereas the former only discharge positively electrified bodies, the latter discharge any electrification, of whatever sign. Battelli and Garbasso, in "Nuovo Cimento," prove that cathode rays acquire the discharging properties of X-rays and Lenard rays when "filtered" through a plate of aluminum or glass, but that the change in properties is not due to the passage, but to the change in the medium surrounding the rays. The proof is conclusive. A charged terminal is mounted in the wall of the vacuum tube. A shutter of aluminum or lead is made to slide over and cover it. The discharging phenomena are the same in kind with or without the shutter, though differing in intensity. The discharging properties of Lenard rays are therefore due, like those of X-rays, to the ionisation of the air.

WIRES TO THE KLONDIKE.

It is understood that the Western Union Telegraph Company is contemplating the laying of a cable to St. Michael's, at the mouth of the Yukon River, and possibly putting up a line to the Klondike gold fields by the way of Juneau and over the mountain passes. The first step in that direction has been taken in the decision to lay open a line from Anacortes, Wash., to Victoria, B. C.

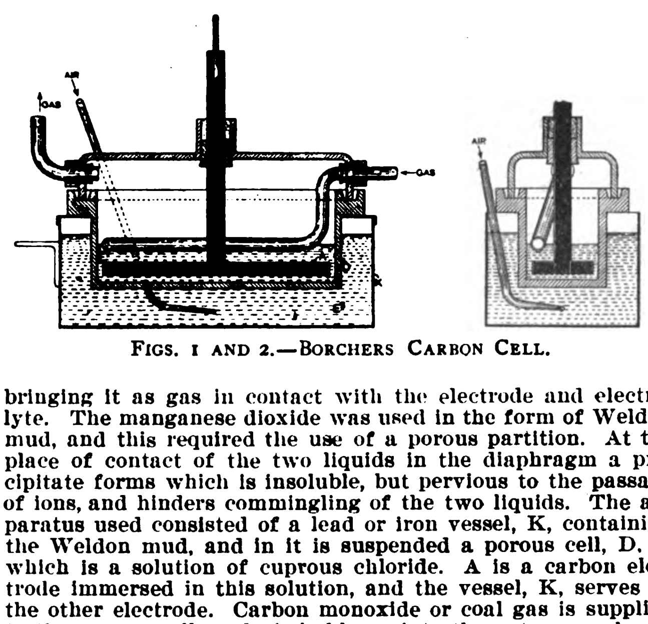
MISCELLANEOUS

THE BORCHERS CARBON CELL.

SOME little time ago Dr. Borchers published an account of a cell designed to produce electrical energy directly from the oxidation of carbon used in the form of its gaseous compounds, notably carbon monoxide. The original idea was to supply CO and air to indifferent electrodes immersed in a solution of cuprous chloride. This substance, having the property of reacting with both oxygen and carbon monoxide, was chosen to bring about the oxidation of the carbon monoxide in such a manner as to produce electrical energy instead of heat. The cell thus contrived was the object of severe criticism, and various experimenters carried out tests which tended to show that the current which was undoubtedly obtained was derived from the dissolution of copper used as an electrode, and was not due to the oxidation of carbon monoxide.

At the annual general meeting of the German Electro-Chemical Society, which was recently held at Munich, Dr. Borchers described various experiments which he had made to determine whether carbon monoxide could be oxidized in an electrolytic cell with the production of current.

Among others he constructed the cell illustrated in the accompanying diagrams, Figs. 1 and 2. In this cell Dr. Borchers used manganese dioxide as a carrier of the oxygen, instead of



FIGS. 1 AND 2.—BORCHERS CARBON CELL.

bringing it as gas in contact with the electrode and electrolyte. The manganese dioxide was used in the form of Weldon mud, and this required the use of a porous partition. At the place of contact of the two liquids in the diaphragm a precipitate forms which is insoluble, but pervious to the passage of ions, and hinders commingling of the two liquids. The apparatus used consisted of a lead or iron vessel, K, containing the Weldon mud, and in it is suspended a porous cell, D, in which is a solution of cuprous chloride. A is a carbon electrode immersed in this solution, and the vessel, K, serves as the other electrode. Carbon monoxide or coal gas is supplied to the porous cell, and air is blown into the outer vessel containing the Weldon mud. The cross-section of the apparatus shown in Fig. 2 makes the arrangement clear. The æration of the Weldon mud may be discontinuous, in which case when the cell ceases to give current the porous cell may be lifted out, a little more lime added to the Weldon mud (which normally contains a certain amount) and air blown through.

Details of the output of cells of this type are given in the form of tables. Thus, using in the porous compartment a solution containing 80 grammes of cuprous chloride, 100 grammes of sal ammoniac, 50 grammes of sulphuric acid, made up with water to a volume of 500 cc., and in the outer compartment Weldon mud as aforesaid, a voltage of 0.61 volt and a current of 0.01 ampere were observed with an external resistance of 100 ohms, and a voltage of 0.07 volt and a current of 0.42 ampere with an external resistance of 0.5 ohm.

DANGERS OF PINTSCH GAS AND TIME TRAIN ORDERS.

A valued correspondent and electrical engineer, who in his early career handled the telegraph key, writes us in reference to the frightful accident which recently occurred on the Denver & Rio Grande Railroad as follows:

Pintsch gas was the cause of many of the deaths. Time train orders instead of definite meeting points was another cause. It appears the freight train had permission to use one hour of the passenger train's time. They used several minutes more than this. When I was a train dispatcher we considered time orders unnecessary and dangerous.

FERRARIS AND ARNO PHASE TRANSFORMER.

The last electrotechnical contribution of the late Prof. Ferraris was a description of "a new system of electrical distribution" by means of the "Trasformatore di Fase," designed by himself and his disciple, Riccardo Arno. It was intended for circuits in which the energy was consumed to nearly the same extent for lighting and for power. The ordinary alternating current was to be sent through the lamps, and the power portion was to be transformed in a special manner to suit the requirements of polyphase motors. The phase transformers have, between the primary and secondary circuit, an intermediate rotating part which is kept in motion on the plan of the ordinary asynchronous motor. Any difference of phase required may be obtained by a suitable adjustment of the number of turns of each coil. The theory of this machine is one of considerable intricacy. It has been attacked by Luigi Lombardi, of Zürich, and compared with practical results. He finds that the transformer obeys most of the laws of the asynchronous motor. Its velocity is very slightly below perfect synchronism. There is a difference of phase between the tension and the primary current which diminishes to a limit as the load is increased. This limit is higher than in the motor, and increases with the difference of phase between the current and the secondary tension. The efficiency is considerably below that of the ordinary transformer, but it may be employed with advantage for starting asynchronous monophase motors.

THE RADIATION OF LIGHT IN THE MAGNETIC FIELD.[1]

DURING the past few months some interesting experiments have been made regarding the partial polarization of radiations emitted by certain luminous sources when they are placed under the influence of a magnetic field. Important investigations in this direction have been made by Dr. Zeeman, of the University of Leyden, who has shown that the perturbations experienced by the ions, under the influence of magnetic forces, produced new periods of luminous vibrations. Continuing this work, Messrs. Egoroff and Georgiewsky (Comptes rendus, April 5, 1897), with the aid of a Rowland grating and a Ruhmkorff coil, have observed a feeble broadening of the lines D_1 and D_2 in the spectra of both axial and equatorial radiations. In investigating the appearance of colored flames of polarized rays by using the Savart analyzer, it was observed that the partial rectilinear polarization of rays directed toward the equator of the magnetic field was easily observed, not only in flames of sodium, lithium and potassium, but in induction sparks between magnesium electrodes. In the cases of carbon, aluminum, mercury, zinc, bismuth and iron, the Savart analyzer showed no in..cation of rectilinear polarization. In a second communication to the same journal (Comptes Rendus for May 3), the results there enumerated may be summed up as follows. The relative quantity of equatorial radiations emitted by a sodium flame, and polarized rectilinearly, varies with the intensity of the magnetic field according to a particular curve. Under the influence of a magnetic field of given intensity, the qauntity of the light polarized rectilinearly, and emitted equatorially by the sodium flame, varies with the temperature of the flame. In studying the change of spectra of metals in a field of considerable intensity, a modification of the method of procedure was adopted, and resulted in the discovery of the rectilinear polarization of the equatorial radiations. Nearly all the metals employed—namely, Cu, Tl, Zn, Cd, In, Mg, Ca, Ba, etc.—showed polarization exclusively for those rays that are easily reversed. The phenomenon, the authors state, "is observed in a very instructive manner for the copper in the green part of the spectrum (the change is very large for the ray 5,105, most feeble for 5,153, and zero for the long waves 5,217 to 5,292). For indium, the change only occurred for the violet ray at 4,510, while the others (6,193, 5,230, 5,900, 4,680, 4,616 and 4,638) were not influenced by the field at all." In experiments with Geissler tubes containing hydrogen and helium, no definite results up to the present have been obtained.
